By far the greatest part of this genus consisting almost only of quite similarly coloured and marked species was described by LORD ROTHsCHILD in 1909 and the outlines adduced here are chiefly based upon his statements, verbally and pictorial. The marking of the forewings almost invariably consists of 2 or 3 parallel transverse lines on a yellow or red ground and frequently of an irregular vitreous spot behind the cell-end. The forewings are in a number of species angled, and these species are closely allied to the species enumerated last

*) **A. ochreogaster** Joicy (53 f). All white with a pale yellow abdomen. This Arctiid was described as *Automolis*, but according to HAMPSON, it is said to belong to the genus *Prumala* (p. 344). Paraguay.

under the *Automolis*, so that the line of separation of the two genera would perhaps be better drawn at some other place. The larvae have nothing to do with the Syntomid-like larvae of the typical *Automolis*; they are scantily haired in uniform light tufts, of a quite normal and inconspicuous, genuine Arctiid larval shape. The *Zatrephes* themselves, according to HAMPSON's new catalogue form a genus to be separated from the butterflies having formerly been denominated so and being now called *Azatrephes*; they have, however (as is already seen from the larvae) nothing in common with the Syntomids to which the *Zatrephes* were formerly reckoned. As an essential difference in the venation from the *Automolis* it is stated that in the hindwing the costal approaches the upper cell-wall, before the middle of the cell, and runs with it for some distance, in order to turn away again behind the middle of the cell. Thereby a small accessory cell is produced at the base; upon this peculiarity great stress is laid by some authors, but it is also found in other greatly specialized groups (*Agaristids* etc.) and it seems to have been of great moment in the separation of the *Hypsiidae* from the *Arctiidae*. — From the fact that almost all the *Zatrephes* have been discovered during the last years we may infer their infrequent occurrence. They are not to be found in day-time, but taken by the lantern.

A. Forewing with a distinct projection or angle above the middle of the margin.

Z. gigantea Rothsch. (52 i) is very similar to the preceding species (*Automolis excavata*), but the *gigantea*, forewing somewhat more obtusely angled, without the light marginal spots and with a large discal vitreous patch composed of several partly fused hyaline spots. Amazon (Fonte Boa).

Z. foliacea Rothsch. (52 i) is much smaller, the hyaline spots almost the same as in *gigantea*, but *foliacea*, the ground-colour is sometimes lighter, sometimes darker reddish yellowish-grey, the two dark transverse lines of the forewing bordered with whitish. The tooth at the border of the forewing is somewhat sharper than in *gigantea*. From the Amazon. — In **griseorufa** Rothsch. (52 i), like the preceding from Fonte Boa on the Amazon, *griseorufa*, the vitreous patch on the forewing is somewhat larger, and the antemedian line runs somewhat curved and less obliquely.

Z. bilineata Rothsch. (52 i) is presumably scarcely to be separated from *foliacea*; the transverse *bilineata*, lines on the forewing run almost quite straight, the antemedian line without any curve; the vitreous spot of the forewing is narrower, distally irregularly defined; from the Amazon and Peru. — **rufobrunnea** Rothsch. (52 i) *rufobrunnea*, likewise from the Amazon, has a more ruddle-red than yellowish-grey ground-colour of the forewings and the two transverse lines diverge very feebly at the proximal margin.

Z. trilineata Hmps. (52 l). Here the colouring is dull ochreous-yellow as in *bilineata*, slightly powdered *trilineata*, with pink, but the forewing has a much smaller hyaline spot and 3 transverse lines instead of 2. Surinam and Amazon. — The form **peruviana** Rothsch. is more white and less yellow, and the pink dusting is very trifling. *peruviana*, From Peru.

Z. cardytera Dyar. (52 l), from British Guiana, has only the proximal transverse line which, however, *cardytera*, is rather thick and not very distinct; the postmedian line is absent. The hyaline spot of the forewing is much larger than in the preceding. The hindwings pink, in contrast with the ochreous-yellow forewings.

Z. flavida Hmps. (= *albotestacea* Rothsch.) (52 i). Forewing monotonously ochreous-yellow, without *flavida*, any transverse lines; the vitreous spot bipartite, rather small. Hindwing brimstone-coloured. French Guiana.

Z. binotata Rothsch. (52 i). Similar to *flavida*, larger, darker, the two transverse lines faintly indicated, *binotata*, the vitreous spot on the forewing confined to 3 hyaline dots. Amazon.

Z. atrata Rothsch. (52 l). Recognizable by the deep dark brown ground-colour. The vitreous spot on *atrata*, the forewing tripartite, the tooth at the border of the forewing almost vanished, but the border in the middle somewhat indented. Demerara (Guiana).

Z. miniata Rothsch. (52 k) is quite similar, larger, the ground-colour of the forewing deep purple- *miniata*, brown, the two transverse lines recognizable as faint shades. Amazon (Fonte Boa).

Z. modesta Schs. (52 k) from Guiana is quite similarly coloured as *miniata*, but the forewing shows *modesta*, 3 parallel, grey transverse lines, and the angle at the border is quite obtuse, scarcely perceptible.

B. Margin of the forewing without a distinct tooth or angle above the middle.

Z. propinqua Rothsch. (52 k). Colouring lighter ruddle-red than in *miniata*, the vitreous spot similarly *propinqua*, shaped, but much larger. Peru.

Z. carmesina Rothsch. (52 k). Colouring as in *propinqua*, but the hyaline spot of the forewing only *carmesina*, about half as large and its distal margin not so deeply indented. Amazon (Fonte Boa).

- fasciola*. **Z. fasciola** *sp. nov.* (52 k) from Teffé (Amazon) shows the vitreous spot below blotted as far as the border above the anal angle. Perhaps only a form of *carmesina*.
- crocos*. **Z. crocos** *Cr.* (= *istria Drc.*) (52 l). Considerably larger, the yellowish hyaline spot reduced to a small curved band situate behind the cell-end of the forewing and projecting beyond the discocellulars downward in the ♂ little, in the ♀ not at all. Thorax and forewing otherwise violettish-brown, in the disc and at the border orange-yellow; speckled red; through the wing some red transverse lines. Hindwing and dorsum of abdomen purple. — Larvae rather scantily haired, when grown up with a black dorsal shabraek exhibiting on each segment 2 light transverse lines and 1 or 2 rows of dots; sides, venter and sham feet are either dark green or purple-red (which is said to be a sexual distinction). It lives on the coffee-tree and yields the imago already after a 6 days' pupal stage. Pupa dark purple-brown. Guiana and Amazon.
- flavipuncta*. **Z. flavipuncta** *Rothsch.* (52 k) from Surinam has, like *fasciola*, the spot on the forewing somewhat prolonged, but not yellow, but purely whitish hyaline; the transverse lines, being fiery red in *fasciola*, are scarcely visible, the whole animal much smaller. In the cell of the forewing a small, but distinct yellow dot.
- rosacea*. **Z. rosacea** *Rothsch.* (52 k). Forewing purple-brown with a narrow vitreous patch composed of 3 or 4 spots; hindwings deep pink, abdomen dark red. Amazon: Fonte Boa and Teffé. — **Z. rufescens** *Rothsch.*, likewise from the Amazon, has only a somewhat broader vitreous patch, more distinct transverse lines and more yellow hindwings.
- brunnea*. **Z. brunnea** (53 a) has the size of the preceding, but through the middle of the forewing extends a broad, darker transverse band, in the cell there is a black dot, and the vitreous spot is formed by a chain of 4 white, distally black dots. Body and hindwing yolk-coloured, the inner-marginal area of the hindwing with a pink tint. Peru.
- dithyris*. **Z. dithyris** *Hmps.* (52 l) is quite similar, but without the vitreous spot, which is replaced by a small white dot between the radials; hindwings crimson. Guiana.
- irrorata*. **Z. irrorata** *Rothsch.* (52 l). Forewing buff, densely strewn with red-brown, instead of the vitreous spot of most of the other *Zatrephes* there are here before the apical area some disperse white dots. Hindwings yellow, tinged pink. Amazon (Fonte Boa).
- variegata*. **Z. variegata** *Rothsch.* (53 a). Forewing similar, but between the cell-end and border there is a yellowish cloud formed of small, dull spots; the hindwing purple-pink, costal margin and fringes white. Amazon (Fonte Boa).
- arenosa*. **Z. arenosa** *Schs.* (53 a). Forewing red-brown with 2 dark transverse lines; behind the distal one, below the costal margin, 3 small white hyaline spots. Hindwings and abdomen purple-pink. French Guiana.
- klagesi*. **Z. klagesi** *Rothsch.* (53 a). Very similar to *variegata*, but the forewing of a clearer ochreous-yellow, the two transverse lines red-brown, the distal one only from the cell-end to the proximal margin; in the disc a white, anteriorly dark hyaline spot. Hindwings pink. Amazon (Fonte Boa).
- ockendeni*. **Z. ockendeni** *Rothsch.* (52 l) is larger, lighter, more thinly scaled and with duller markings, the proximal transverse line more distinct than the distal one; in the cell a black dot; in the disc a whitish, irregular hyaline spot. Hindwings whitish, feebly suffused with pink. Peru, Bolivia.
- bicolorata*. **Z. bicolorata** *Rothsch.* (= *sublutescens Rothsch.*) (53 a). Colouring and size of *ockendeni*, but instead of the white discal spot before the apical part of the forewing only a black dot, both transverse lines dull, but just in front of the apex of the forewing yet a small, fine dot; hindwings yellowish. Peru; presumably only a slightly different ♀ form of the preceding.
- cruciata*. **Z. cruciata** *Rothsch.* (53 a). Smaller than *bicolorata*, but coloured the same. The antemedian transverse line is situate as in the preceding species, but the postmedian one extends from the costa in a proximally convex bow towards the anal angle, and between it and the antemedian line there is a horizontal cross above the middle of the proximal margin. Hindwing whitish, proximal half pink. Amazon (Fonte Boa).
- albescens*. **Z. albescens** *Rothsch.* (53 a). Wings very light, almost bone-white, only the distal margins darker. Forewing with the usual transverse lines being almost parallel and scarcely convergent at the proximal margin and running quite straight. At their uppermost ends a minute black dot scarcely noticeable in the ♂. Abdomen purple-red. Amazon (Fonte Boa).
- subflavescens*. **Z. subflavescens** *Rothsch.* (53 a). Almost exactly like *albescens*, but in the ♂ the border of the forewing is almost straight, the forewings being consequently more pointed. Instead of the hyaline spot on the forewing of most of the *Zatrephes* there are here 2 distantly separated hyaline dots. Amazon (Fonte Boa) and Guiana.
- iridescens*. **Z. iridescens** *Rothsch.* (= *nitida Rothsch. nce Stoll*) (53 b) is almost exactly like the preceding, but the wings somewhat opalescent and the two transverse lines somewhat divergent towards the proximal margin. Amazon (Fonte Boa) and French Guiana.

Z. nitida Stoll (nec Rothsch.) is extremely similar to the preceding, but 2 dull lines in the middle *nitida*. of the forewing cut each other (like in *cruciata*) on the submedian vein, and behind the cell-end there is a small band of 4 or 5 small diaphanous light spots. The wings above with a slight mother-of-pearl lustre; hindwings pink with white fringes. Guiana and Peru.

Z. ossea Schs. (53 b). Forewing dull whitish with a brown border and 2 thick, oblique, brown transverse *ossea*. lines. In the hindwing the whole proximal area is purple-pink, like the abdomen. French Guiana.

Z. lentiginosa Rothsch. (53 b). Forewing yell-coloured, the two transverse streaks distinct only in *lentiginosa*. the inner-marginal area; between the radials a white dot finely excircled dark. Hindwing yellow with a red border and white costal area. French Guiana; discovered by LE MOULT.

Z. pseudopremolis Rothsch. (53 b) is quite unlike the genus by approaching species of the same *pseudopre-* range from other genera (*Neonerita arcifera*, *syriassa*, *Eupseudosoma affinis*, *Premolis rhyssa* etc.). Adjoining *molis*. to the purple-violet basal part a large, diaphanous pale yellow apical part. A purple-brown costal stripe sends from the apex a small faint costal band 2 or 3 mm far into the wing. Hindwings and abdomen pale pink. Peru.

Z. flavonotata Rothsch. (53 b) is somewhat similar, the brownish-violet preapical spot more intense, *flavonotata*. at the basal part a lemon-coloured semicircular spot is situate on the costa. Amazon.

49. Genus: **Azatrephe** Hmps.

5 species, allied to the preceding, chiefly distinguished by the venation of the hindwing, where the upper cell-wall, being unparted and unforked, is continued to the border. They are small butterflies with a large, lobated hyaline spot in the disc of the forewing. The centre of their range is like that of the preceding genus on the Amazon, presumably also near Fonte Boa; from there they are distributed as far as Guiana to the north-east and Peru to the south-west. The species in their habits do not differ from the allied genera and are probably without exception taken at the light.

A. paradisea Btlr. (46 m). Smaller than the smallest *Zatrephe*, recognizable by the large, hyaline *paradisaea*. postcellular spot with a slight silky lustre, on the forewing. Forewing golden yellow with a silvery reflection and a red, net-like marking. Proximally to the hyaline spot a brown oblique line runs from in front of the middle of the costa to beyond the anal angle to the border. Hindwings tinted pink, the costal part somewhat transparent. Abdomen of the ♂ and ♀ purple-red. Amazon, Peru.

A. traili Btlr. (46 m). Easily recognizable by the somewhat irregularly shaped, above narrower, greasy- *traili*. lustrous hyaline spot in the distal area of the forewing, extending from the 3rd costal vein to the submedian space; it is bordered with scarlet and somewhat irregularly defined towards the orange-yellow basal part intermixed with red lines and small spots. Hindwings tinted pink; abdomen above hemochrome. From the Amazon.

A. discalis Wkr. (46 m). The hyaline spot of the forewing is here very large and is defined towards *discalis*. the whitish and also somewhat silvery lustrous apical and basal areas by brown, distally very dull delimitations. Hindwing whitish, towards the border faintly tinted rosy. Abdomen in the ♂ buff, in the ♀ silvery white. Amazon. Peru.

A. argyrotis Hmps. (46 m) is almost like *discalis*, but the non-hyaline part of the forewing almost *argyrotis*. entirely silvery, with very few transverse markings. Peru.

A. fuliginosa Rothsch. (46 m). The typical form has, except the hyaline spot, almost quite purple- *fuliginosa*. brown forewings, and also the hindwings and abdomen are dark brown. There occur, however, transitions to the preceding species as well as quite dark forms, of which already LORD ROTHSCHILD figures a number of intermediate forms. We propose the following denominations only for the extremest forms entirely deviating from the type: ab. **transiens** *nom. nov.* (46 m) for the specimens with very light, partly silvery lustrous embed- *transiens*. ments in the forewings, and ab. **invenestrata** *nom. nov.* (46 m) for such with the hyaline spot being covered *invenestra-* with brown. In the latter the hindwings and abdomen are dark-brown, in ab. *transiens* lustrous yellowish-white, *ta*. faintly powdered with brown. — Amazon: Fonte Boa.

50. Genus: **Castrica** Schs.

This genus was established for a species having been known already for 150 years. It is closely allied to the *Automolis*, but it has a feebly angled border of the forewing, which is exhibited only by those *Automolis* of which it is doubtful whether they belong to the group. It otherwise greatly resembles in the exterior the *Aut. tybris*-group (52 g), differs, however, by the middle and lowest radials (= uppermost median vein) of the forewing not rising from the same place, but by a distinct lower discocellular being present in *Castrica*.

Besides, the ♂ of *Castrica* has an oval seent-pad on each wing; on the forewing in the submedian space, where it forms the centre of a reflecting spot, on the hindwing before the upper cell-angle.

phalaenoides.

C. phalaenoides Drury (= *oweni* Schs.) (53 b). Forewing light olive-grey, in the cell, in the disc, below the apex and along the border yellowish diaphanous spots; the ground-colour towards the proximal margin more yellow. Hindwings pale yellow, abdomen orange. From Honduras through Central and South America to Bolivia. It varies rather much, though not geographically.

sordidior.

C. sordidior Rothsch. (53 c) is darker than most of the *noides*, towards the proximal margin not distinctly more yellow, the hindwings dingy white, the abdominal dorsum dark grey. Described from Trinidad and the Amazon (Fonte Boa); the figured specimen from Villavicencio in Colombia (from where, however, there are also *phalaenoides*).

51. Genus: **Thyrarectia** Hmps.

This genus (*Parathyris* Hbn.) was established for the singular *cedo-nulli*, but so narrowly delimited that new genera had to be founded already for its nearest allies. I comprise therein 3 well-known species, all of which are sepia-brown, with hyaline spots partly covered with fine dots, on the forewing, and a rather sharp angle at the border, where the middle radial terminates. In the ♂ the collar is somewhat erect, the tibiae of all legs are long-haired, the last tarsal joint of the forelegs with a small curl of hair; proboscis small and not capable of action.

cedo-nulli.

Th. cedo-nulli Stoll (53 e). A large and conspicuous butterfly. The hyaline apical area is obliquely cut off from the disc; a large hyaline spot in the cell and one at the middle of the border, divided into two parts by a submarginal chain of brown spots. Abdominal dorsum in the ♀ banded orange; venter chalky-white. The butterfly is very widely distributed, but it is of rare occurrence everywhere and, to my knowledge, it was hitherto only taken at the light. The largest imagines occur in Bolivia, where it attains a size of close to 70 mm. We figure a Bolivian ♀ from the Rio Songo. From Guiana through Brazil as far as Rio de Janeiro, Bolivia and Peru.

semivitrea.

Th. semivitrea Joicey (53 c). In this species the hyaline spots are fused to such an extent that the whole apical half of the forewing is hyaline, only below the apex there is an antemarginal brown, distally pointed spot. Abdominal dorsum in the middle yellow. Peru, on the Upper Amazon.

frigga.

Th. frigga Dre. (53 c). Apical hyaline spot similar as in *cedo-nulli*, the hyaline spot in the cell quite small, the distal vitreous spot large, intensely dotted. This species has been separated as the genus *Gonotrephes* Hmps. Bolivia (Rio Songo). Peru and the Amazon District, more common than the preceding species, but much smaller.

52. Genus: **Zaeavius** Dyar.

The species on which this genus is based is unknown to me in nature. Proboscis small; palpi bent up as far as the middle of the forehead, antennae doubly combed with short branches; abdomen in the ♂ with a large anal tuft. Forewing at the apex somewhat sickle-shaped, the border below it excised, projecting again on the middle radial. The uppermost radial on a common pedicle with the 2nd to 5th subcostal vein. The only species known comes from Guiana.

calocore.

Z. calocore Dyar. Size and approximate shape of *Thyrarectia frigga* (53 e). Head and body orange, tinted red-brown. Forewings yellow, suffused with red-brown. Middle of costa white, before the apical part a small white transverse spot and a dot below it. On the anal marginal half there is a laciniiform, semi-transparent spot, the apex of which extends as far as behind the cell-end. The latter is surrounded by a flesh-colour; hindwings white diaphanous, abdomen pink. From Hoorie in British Guiana. Only the type seems to be known, in the National Museum at Washington.

53. Genus: **Epimolis** Dyar.

ROBERTO MUELLER, in 1913, discovered a butterfly from Misantla in Mexico, strikingly resembling *Zatrephes flavonotata* (53 b), but differing in the venation by no vein on the hindwing proceeding from the upper cell-wall towards the costal margin; only very shortly before terminating into the border the subcostal bifurcates. Thereby, as well as by the longer palpi rising in front of the forehead, the genus differs from the otherwise similar *Zaeavius*.

zatrephica.

E. zatrephica Dyar. Almost exactly like *Zatr. flavonotata* (53 b), from which it is exteriorly easily distinguishable by the yellow costal spot at the base of the forewing not forming one large semicircle, but 2 smaller ones following one upon the other. Mexico.

54. Genus: **Pseudalus** Schs.

In the way it is composed at present, the genus is rather abnormal. Proboscis mostly feeble, palpi sometimes rising before the forehead, but also quite stunted, the middle joint being also much shorter. Antennae combed or ciliated in tufts; cell of forewing closed sometimes with deeply, sometimes with scarcely angled discocellular. Venation of hindwing different nearly in every species. Preponderantly yellow species marked or tinged with red, of a very small size rising to a tolerably medium size. Nothing is known of the life-history.

Ps. leos Drc. (53 d), from Ecuador, is small, golden yellow, with lighter hindwings and often reddish dorsum of abdomen. The forewing shows 2 oblique brown transverse lines, an antemedian one being in typical specimens somewhat interrupted, continuous, however, in the smaller *occidentalis* Roths. (53 d), and a postmedian one from before the apex to the middle of the proximal margin. Between both there is a punctiform spot at the cell-end, being distinct in typical specimens. Bolivia and Peru. — **aurantiacus** Roths. (53 d), from Surinam, shows the cell-dot almost vanished, both lines, however, thick and coherent, the postmedian line almost quite straight. — In **strigatus** Roths. (53 c), from Guiana and Peru, the cell-dot in the ♀ is faint, the antemedian oblique line angled below the costa. — Range from Guiana to Bolivia and Peru; some of the forms mentioned here are probably distinct species, but they are much more closely allied to each other than to the other species of the genus.

Ps. limonia Schs. Quite similar to the preceding in size, shape and colour; like there the forewings are dark yellow, the hindwings whitish, but the forewings show only very fine cell-dots, of the transverse lines either nothing at all is to be seen, or their position is only indicated by very fine (3 antemedian, some postmedian) dots. Abdomen whitish. South Brazil.

Ps. salmonaceus Roths. (53 d). Forewing and body above of a delicate salmon-colour, margins, veins and a narrow stripe in the submedian space of the forewing yellow. Hindwing in the ♂ bone-white, in the inner-marginal area faintly tinged pink. The ♀ is much darker, suffused with a deep pink, and the hindwings are dark pink. Peru and Bolivia (from the Rio Songo).

Ps. pseudalus Roths. (53 d) is the largest species. Forewing honey-coloured, with a thick, dark spot round the whitish transverse vein, and traversed by 6 or 7 partly incomplete, parallel, red-brown dentate lines or macular chains. Hindwing in the ♀ (the ♂ is unknown) deep pink, towards the costa and at the proximal margin lighter. Amazon: Fonte Boa.

55. Genus: **Neidalia** Hmps.

The 4 species composing this genus have no proboscis, but rather long, somewhat rising palpi. The border of all the wings is rounded, wings and body like in the preceding yellow, tinged red, with transverse lines on the forewing, similar as in most of the *Zatrephes* and *Pseudalus*. The venation is in both quite the same except a trifling deviation in the subcostal system of the forewing: the cell of the forewing is more than half the length of the wing, bipartite by the discocellular being angled, that of the hindwing being shorter and broader, clean cut off. The former distant separation from *Pseudalus*, appears to be somewhat artificial.

N. irrorata Roths. (53 d) resembles in the habitus yellow specimens of *Eupseudosoma bifasciata irrorata*. (50 a), *Zatrephes lentiginosa* (53 b), *Pseudalus strigatus*, *aurantiacus* (53 d), and others. Veined and strewn orange-red, forewing with 2 dark transverse lines, the postmedian one forming an arch below the costa towards the margin. In the ♀ the resemblance to *Pseudalus strigatus* is increased by the forewing showing a dark punctiform spot at the cell-end and by its transverse lines being tinged deep red.

N. dognini Roths. (53 d) has more intensely red forewings, and the two transverse lines are more remote from each other at the proximal margin. Peru.

N. ockendeni Roths. (53 d). Coloured like *dognini*, but the transverse lines of the forewing at the costal margin more than twice as far remote from each other, the distal one straighter. Peru.

N. villacresi Dgn. Much larger; here the distal transverse line is absent, only the proximal one being present; it cuts a light yellow cuneiform streak situate in the cell and a light yellow spot below the cell. Veins in the distal area of the forewing black. 46 mm. Ecuador.

56. Genus: **Phaeomolis** Hmps.

Allied to the forms of *Aphyle* and *Prumala*, and like them with a strong proboscis. The venation is not homogeneous, that of the hindwing in the ♂ sometimes confined by scent-organs. By most of the species approximating the exterior of other genera, the colourings of the genus have become very multiform.

- manora*. **Ph. manora** Drc. (53 e) resembles some *Neaxia*, *Amasia*, *Prumala* etc. Body and forewings honey-coloured, covered with numerous small rings and ovals which are distinctly encircled with red. Hindwings of a lighter yellow, towards the costa lighter, towards the margin tinged orange. Peru.
- lepida*. **Ph. lepida** Schs. from Costa Rica is slightly smaller, but instead of the rings it has small blackish and red spots partly confluent in the basal part and near the apex of the wing and forming a large, cap-shaped cloud at the proximal margin. The hindwing tinged rosy in the proximal half.
- obscurata*. **Ph. obscurata** Bttr. (53 e). Forewings paler yellow, powdered with grey; this dusting flows together to oblique transverse bands. Hindwings pink. Amazon.
- mera*. **Ph. mera** Schs. (53 e). Larger; the greyish-brown dusting of the forewing covers the whole wing, leaving free only a submarginal row of small yellow internerval spots. Hindwing dull whitish, the border and the whole proximal half likewise suffused with brown. From the lower cell-angle, between the radials, extends a large, diaphanous whitish cuneiform spot intersected by the lowest radial (uppermost median). The species looks like an *Automolis* and like that it has also a variegated body; abdomen blackish, the 3 penultimate rings and the head orange, thorax dark brown, marked white. Costa Rica.
- brunnescens*. **Ph. brunnescens** Rothsch. (53 e). Smaller, but the abdomen, on the contrary, anteriorly and at the apex orange, the 3 penultimate segments rather darker. Instead of the large cuneiform spot, the otherwise greyish-brown forewing shows only yet a minute white punctiform spot behind the cell-end, which in the Bolivian form **unicolor** Rothsch. from Buenavista grows quite indistinct. Hindwing with a broadly dark shaded border. The typical form from Fonte Boa (Amazon).
- similis*. **Ph. similis** Rothsch. (53 e) resembles *Automolis ockendeni* (52 e) and with the latter also numerous other *Heterocera* (Arctiids, Syntomids, Geometrids) of its range. Quite sooty blackish-brown with a broad, orange transverse band through the wing. Fonte Boa (Amazon).

57. Genus: **Syntomostola** Dgn.

The only species forming this genus so very much resembles a Syntomid in the habitus and colouring, that it is much rather confounded with the latter than with an Arctiid. It actually resembles a Syntomid by the extremely reduced cell of the hindwing, whilst that of the forewing is long and broad. Proboscis well developed, palpi thin, but with a very long middle joint; body slender, abdomen projecting far beyond the anal angle. Hindwing of the ♂ (the ♀ is unknown) with a lobularly extended anal part.

- xanthosoma*. **S. xanthosoma** Dgn. (53 e). Forewing except border and cell-end, hindwing in the middle hyaline, otherwise black; abdomen orange. Discovered by A. H. FASSL near Medina in Colombia.

58. Genus: **Hypidalia** Hmps.

Preponderantly yellow butterflies with a pink abdomen. The anal part of the hindwing not lobated, the palpi much shorter and thicker than in *Syntomostola*. HAMPSON inserts the genus before *Cissura* (p. 338), from which, however, it differs by the absence of vein 5 in the hindwing, and by considerable differences in the veins of the forewing. Of the usual Arctiid shape, as it is found in the *Spilosoma*, *Phissama* etc. also in the palearctic. Only 2 species are known.

- sanguirena*. **H. sanguirena** Schs. (53 e) is brownish-red with black dots on the tegulae and across the dorsum of the abdomen; forewings yolk-coloured, the veins and 3 dentate transverse lines, the middle one of which is double, are red, the hindwings pink. From French Guiana.
- enervis*. **H. enervis** Drc. is much smaller (40 mm); forewings yellow with a white costal and proximal margin, on which there are purple basal streaks. Round the cell-end a purple-grey discal spot, between it and the border a transverse row of dark punctiform spots. Hindwings in the ♂ purely white. Rio, Petropolis and Paraná. Apparently rare.

59. Genus: **Hyperandra** Hmps.

The small butterfly forming this genus is so well distinguished by the shape of the ♂ that it cannot be mistaken for any other. The forewing is extraordinarily broad, particularly by the widening of the submedian space. The proximal margin passes over into the distal margin quite uniformly curved, so that there is no angle whatever at the turning. The hindwing is deeply indented in the middle of the border, and both wings are covered with a distinct scent-fur on the under surface.

H. appendiculata *H.-Schäff.* (45 f). Forewing dull violettish-grey with a light yellow marginal part. *appendiculata*. hindwing dull bone-white, in the costal part an ochreous-brown scent-spot on a creasy lustrous reflection. Brazil; the butterfly is apparently widely distributed and occurs also near Rio de Janeiro, but it is rare.

60. Genus: **Thyromolis** *Hmps.*

In common with *Hyperandra* it has a distorted hindwing the anal part of which is lobated, the lobe, however, being besides inverted. At the inversion itself a scent-pencil apt to be spread out. The hindlegs show long hair-brushes on the femora and tibiae. The cell of the forewing is of scarcely half the length of the wing, that of the hindwing still shorter. The only species of this genus exhibits the widely distributed colouring of numerous *Neritos*, *Paranerita*, *Hyponerita* etc.

Th. pythia *Drc.* (53 f). Forewing with a purple-brown basal half intermixed with yellow and violet, *pythia*. small spots, and a diaphanous yellow apical part; before the apex itself a purple-brown, circular spot with a darker pupil and a lighter bordering. Hindwing yellow with a deep orange inner-marginal area and a costal area dusted with brownish. From the Rio Songo in Bolivia; discovered by O. GARLEPP.

61. Genus: **Demolis** *Hmps.*

Distinguished from the preceding genus by the less distorted shape of the male butterflies. Still both wings show a rather broad submedian space. On the forewing the first subcostal vein branches off shortly before the upper cell-angle; the 2nd rises with the footstalk of the others from the cell-angle itself, from which also the upper radial rises; the cell is long and narrow. In the hindwing vein 5 is absent and the costal parts from the subcostal only behind the cell-end. Only 1 species:

D. albicostata *Hmps.* The species greatly reminds us of *Prumala albicollis* *Fldr.* (44 i) and of *Automolis albicostata sordida* *Rothsch.* (52 f), but it is somewhat smaller, the dark basal part of the forewing more reddish-brown than violettish-brown, with a purely white costal margin, the light marginal third of the forewing being yellow. Abdomen dark red, hindwings tinged light pink. From South Brazil.

62. Genus: **Protomolis** *Hmps.*

Proboscis strong, palpi obliquely rising, ♂ antennae doubly combed with rather long teeth. Wings of the common shape, the forewing with a cuneiform cell of almost two thirds of the length of the costa. On the forewing the upper median vein rises before the lower cell-angle, the lower radial above it; the two first subcostal veins branch off before the cell-end, the transverse vein is slightly angled. In the hindwing the submedian area in the ♂ is scarcely half the width of *Hyperandra* and neither attains that of *Demolis*. Only 1 species is known, an insignificant butterfly looking somewhat like a *Biturys* or *Agoraea*.

P. promathides *Drc.* (44 b). Dull white, the forewing finely dusted dark, abdomen hemochrome with *promathides*. black dorsal dots. Mexico.

63. Genus: **Epierisias** *Dyar.*

Of the usual shape, but immediately recognizable by the long palpal terminal joint attaining almost the size of the middle joint; thereby the palpi project far. On the forewing the two subcostal veins rise before the upper cell-angle, the middle discocellular is quite obtusely angled, the two lower radials are short-petioled. In the hindwing all the veins are present. Only 1 species.

E. eschara *Dyar* (53 f). Bright orange-yellow, head and thorax of a deeper colour, like the costa *eschara*. of the forewing; the disc of the forewing slightly tinged reddish. Hindwings coloured the same. In great contrast with the orange-pink body and wings are the long legs and antennae. Mexico, rare.

64. Genus: **Purius** *Wkr.*

The only species forming this genus is an insignificant, brown Aretiid of an expanse of 38 mm, distinguished by both wings having areolae. In the forewing the 2nd subcostal vein anastomoses with the footstalk of the 3rd to 5th in such a way that the areola produced thereby is as long as the free part of the 3rd subcostal vein. In the hindwing a basal areola is formed by the costal approaching the upper cell-wall only close before the middle of the cell. But right behind the middle of the cell it separates again from the subcostal.

pilumnia.

P. pilumnia Stoll (= sordidus Wkr.) (53 f). Head, thorax, and forewings light brown, the forewing densely strewn with blackish, particularly at the costa, cell-end and apex small blackish spots; hindwings diaphanous brown, abdomen black and banded dark pink. Costa Rica to the Amazon.

65. Genus: **Ammalo** Wkr.

This genus is very little homogeneous and is partly indistinct. The venation is very regular, offering no peculiarities whatever, the wings themselves show neither distortions nor scent-organs. The most conspicuous are the ♂ antennae being in some species very long and strongly combed, attaining a length of more than half the length of the costa. Across the base of the abdomen a long fleec of hair is spread. We come across all sizes, of medium size to large size and with colourings changing from dark brown and variegated to a diaphanous white; in their geographical range the species extend from the United States to South Brazil.

Proboscis strong, palpi with a stunted terminal joint. Forewings sometimes with a pointed apex, with a narrow, euneiform cell and an angled discocellular. The 1st subcostal vein branches off before the upper cell-angle, the 2nd together with the footstalk of the others from the cell-angle, from which also the uppermost radial rises. The radials 2 and 3 come from the lower cell-angle, mostly — though apparently not always — together with the upper median vein. — The larvae, as far as they are known, are genuine bear-caterpillars, with tufted velvety hair, without any pencils or hair-brushes. Some species are common, but are almost invariably taken only at the light.

tenerosa.

A. tenerosa Dyar (53 f). The smallest species, all white, only the collar, the base of the costa and abdomen (except the base) yellow; abdomen above and laterally with a row of dots. Discovered by ROBERTO MUELLER in Misantla in Mexico.

tenera.

A. tenera Hbn. (= collaris Fitch, antica Wkr.) (53 f, g). Very much like the preceding, not so purely white, head and thorax as well as abdomen yellow, the latter with rows of black dots. Beneath the costal part of the forewing is sooty dark except the apical part. Atlantic states of North America. — Whilst in typical specimen the costal part of the forewing appears yellow, in the Californian form: **sciurus** Bsd. (= yosemitae Edw.) only the costal basal part is faintly hued yellowish, and the prothorax is more greyish. — The grown-up larva is dull white with long, silky grey hair on tubercles being dotted black; stigmata black-curved; head flesh-coloured. It lives on *Asclepias* and *Apocynum* and the species is in some districts (e. g. in Carolina and Pennsylvania) not uncommon.

eglenensis.

A. eglenensis Clem. (= inopinatus Edw.) (53 g). Denominated by its resemblance to *Euchaetias egle* (39 f). ♂ dull greyish-brown with a yellow abdomen dotted black, and a white frons. In the ♀ the wings are dull whitish with an orange-yellow costal stripe. — Larva reddish-ochreous with an orange-yellow head, black tubercles and silvery grey hair on them; on *Asclepias tuberosum*. Southern states of the eastern part of North America.

insulata.

A. insulata Wkr. (= cadaverosa Grt., affinis Grt., aurata Btlr.) (53 g). Shape and size of *eglenensis*, but body and wings above unicolorously yellow. — **aravaca** Jord. does not differ exteriorly from *insulata*, but in the structure of the genitals. — Larva black, the 1st, 3rd, 7th and 9th segments brownish-red; across the dorsum a row of white spots, next to them thin subcostal streaks. Hair black, quite in front and behind intermixed with white hairs. Distributed from Florida through Mexico and Tropical America to the south as far as South Brazil and North Argentina, in some districts very common.

cirphoides.

A. cirphoides Rothsch. (53 g). Size of the preceding, but paler yellow, particularly in the disc of the forewing. The forewing is slightly brownish below an apical oblique streak and the fringes before the apical marginal half; also on the median, at the proximal margin and sometimes also above the submedian there is brownish scaling; discovered by FASSL in Colombia, on the Tolima, and the Quindin Pass.

bipunctata.

A. bipunctata Wkr. (53 g). Body and forewing ochreous, densely tinged with red-brown, at the cell-end a darker mark; the hindwings lighter, more yellowish-white, somewhat diaphanous. Pará.

signata.

A. signata Wkr. (53 g). The species which is said to originate from „Brazil“ and is not before me, shows a superficial colonial resemblance to species of *Hyperthaema*, such as *H. sanguineata* (43 c). Body and forewings brick-red, watered by yellow, undulate transverse stripes, with a white spot encircled by black near the base, a similar antemarginal one, and small dark spots in and behind the cell. Hindwings dull whitish.

constellata.

A. constellata Dgn. (53 i). Repeats the colouring being widely distributed in South America of *Tessellata sertata* (42 f), *Ochrodota pronipides* (43 a), different *Carathis* etc. Forewings dark sepia-brown with light yellow patches filled up with brown rings in the basal part and before the apex. Hindwings dark brown, cell and inner-marginal area lighter. Colombia.

A. paranomon Dyar (53 h) discovered by ROBERTO MUELLER near Zacualpan (Mexico), resembles *paranomon*, more certain *Pachydota*, *Mazaeras* etc. Forewings dark brown, with a broad, blackish transverse band before and behind the middle and at the margin, as well as a dark, costal demi-band above the cell-end. The inner-marginal base, hindwing and abdomen pink, hindwing with a dark distal band. Rare.

A. trujillaria Dgn. (53 i) from Peru resembles *Amastus* occurring there. Forewing dirty yellowish-brown, watered dark, and with a brown marginal band proximally undulately bordered. Hindwing lighter, only in the apical part dark. A large species. *trujillaria*.

A. helops. By this name the members of entirely different South American genera are presumably confounded even to this very day. This is easily possible, since on the one hand two forms (those with more unicolorously dark forewings and those with spotted yellow forewings), although they are easily discernible and are taken to be subspecies *), occur beside each other in certain habitats, on the other hand by reason of the entirely deviating larvae yielding the *helops*. Moreover, they are probably confounded with similar *Mazaeras* or *Elysius* (e. g. *cingulata*, 53 h). — **helops** Cr. (= *fervidus* Wkr.) (53 h) has the dark forewings intermixed with honey-coloured spots of an irregular shape, and the orange-yellow abdomen is banded black; its base, as well as the hindwings, tinged pink. Mexico, Central and South America, here particularly in the north and east. — In the south and west, but to the north as far as Costa Rica, we find the form with dark forewings being little or not at all spotted yellow, **megapyrrha** Wkr. (= *chrysogaster* Wkr., *impunctus* Grt.) (53 h). — The larva of the typical *helops*, which is lying before me from Mexico owing to the kindness of Prof. Dr. DRAUDT, is reddish greyish-brown, covered with a dense, short, velvety black, felt-like fur, the head reddish yellowish-brown, lustrous. In contrast with this, it is quite differently figured, greyish-brown, also the head, covered with thin tufts of long white hair; across the dorsum extends a broad white band bordered with dark and longitudinally traversed by three rows of green dots. (This latter larva will presumably much rather yield *Mazaeras conferta*). *helops*. *megapyrrha*.

A. klagesi Roths. (53 i) has unicolorously dark brown wings; the head, thorax, and apex of abdomen are red, the abdomen otherwise above black. According to HAMPSON, it belongs in the genus *Tessellartia*. From Fonte Boa (Amazon). *klagesi*.

66. Gattung: **Mazaeras** Wkr.

Large butterflies with a glaringly coloured body being uncommonly clumsy in the female, with a fully developed proboscis, the fur-like haired palpi being bent up and projecting somewhat, and in both sexes with doubly combed, rather long antennae. On the forewing the 1st and 2nd subcostal veins branch off before the cell-end, the latter anastomoses with the pedicle of the 4th and 5th, forming a long arcola; the discocellulars on both wings rather long, the transverse vein slightly bent in. Only 3 species are known, being rather similar to the palearctic *Arctia* in the structure; but whilst the stout *Arctia*-♀♀, as for instance those of *A. hebe*, are not well adapted for flying and, in depositing the eggs, run mostly only in a whizzing way along on the soil, the ♀♀ of *Mazaeras* easily rise to a considerable height and even fly across broad rivers. Their chief range is in South Brazil, where they come to the lantern rather late in the evening. As to the larva, comp. what has been said in *Ammalo helops*.

M. conferta Wkr. (53 h) is similarly coloured like the very variable *A. helops*, but of a much stouter structure, with shorter and feebler antennae. Hindwings purple, with a more pointed apex. Abdomen more thickly spotted black. ♂ considerably smaller than the ♀♀. Particularly on the eastern coast of South Brazil. *conferta*.

M. melanopyga Wkr. (53 g). Dark wood-coloured, forewing with a light dot at the cell-end, before the marginal area a small, undulate, light band. Hindwing in the proximal part thinly scaled, at the base reddish. Dorsum of abdomen as far as the middle of the abdomen pink, terminal half of abdomen, venter and sides of abdomen black. Eastern coast of Brazil, from Pernambuco to Sa. Catharina; the figured specimen from Santos. *melanopyga*.

M. janeira Schs. (53 i). Smaller, forewings more striated. Hindwings of a lighter greyish-brown, abdomen yolk-coloured, with black dorsal and lateral spots. South Brazil. *janeira*.

67. Genus: **Elysius** Wkr.

This genus, containing many species, forms a great contribution to the neotropical Arctiids. In tropical South America it proceeds relatively far to the south and in Mexico it is represented yet with rather many species, but it does not reach the United States any more. They are of a compact structure, the head is stout, woolly haired, with a strong proboscis; palpi densely haired with a short basal joint, long middle joint and stunted

*) ROTHSCHILD. Novitat. Zoolog. 17. p. 34.

terminal joint. ♂ antennae long and densely doubly combed, shorter than those of *Ammalo*, but longer than those of *Mazaeras*. Body mostly stout, sometimes clumsy, but in the species with large hindwings sometimes also slim. Particularly the slender species, deviating considerably from the type, have very long legs. Across the base of the abdomen a dense hairy fleece is spread. Forewing with a long cell and an inwardly angled transverse vein, without an areola. Hindwing sometimes with a straight border and a longish anal part. The animals keep very much out of the way and are presumably without exception taken at the light.

- ammaloides*. **E. ammaloides** Rothsch. (*ammeloides* in tab.) (53 i) strongly recalls a small *Ammalo helops* by its colouring, and particularly by the contours of the wings (the border of the forewing being somewhat indented) and by the long and strong ♂ antennae, but the forewing without the orange spots being often very numerous in *helops*, the abdomen more red than yellow, particularly the base strongly covered with red hair, the abdomen otherwise feebler and with duller transverse stripes. Amazon and Peru.
- francki*. **E. francki** Schs. (53 h) is similarly coloured, but of a more clumsy structure, the shape of the wings more like that of a *Mazaeras*, for which reason the species was often described as such a one. Forewing dark brown, only at the base of the proximal margin reddish-yellow. Hindwing transparent yellow-reddish, towards the margin darker, thinly scaled, but strongly haired; abdominal dorsum in the basal half red-haired, otherwise yellow-coloured with black transverse spots. South Brazil, Central Brazil and Bolivia. Bolivians have a darker head and already approach the following form.
- soteria*. **E. soteria** Drc. (54 a) is very closely allied to the preceding, of which it is the southern representative, from Argentina; the last 4 joints of the abdomen dark yellowish-brown, the hindwing in the ♂ whiter, only the border narrowly yellowish-pink.
- mediofascia*. **E. mediofascia** Joicey. Only the ♂ is known, somewhat larger than the preceding, the forewings red-brown, with dark brown and orange transverse striae, at the base of the proximal margin red; below the costa near the base an orange spot strewn with red, and one below the middle of the cell, a small one in the cell-end, behind the middle of the wing a macular band, and a broad band at the border. Hindwings orange, at the costal and proximal margin tinted red. Body orange, head and thorax coloured red, abdomen with a red base and black lateral spots. Peru.
- cingulata*. **E. cingulata** Wkr. (54 a) is much larger, the thorax spotted black and the abdomen with sharp black bands. The orange spots in the forewing are more dispersed, the hindwings of a bright flesh-colour. South Brazil (and Jamaica?).
- magnifica*. **E. magnifica** Rothsch. (54 a) is still much larger, instead of the orange-yellow spots of the forewing there are yellowish-brown shades; hindwings purple; abdomen with such broad black bands, that there only remain narrow transverse bands of the ground-colour. Peru.
- proba*. **E. proba** Schs. (54 a). Anterior body and forewings darker, abdomen and hindwings lighter dull yellowish-brown; the forewings feebly chased brown. Mexico, Honduras; the figured ♀ from Misantla.
- pachycera*. **E. pachycera** spec. nov. (54 b) from the Rio Songo in Bolivia is quite unicolorously dark brown, only at the cell-end and at the border of the forewing darker shades, the hindwings less yellow, darker brown.
- aeschista*. **E. aeschista** Dgn. (54 b) is quite similarly coloured as the preceding, but the body much more slender and the antennae much longer, almost to four fifths of the length of the costa, and therefore scarcely congeneric with the preceding. Colombia; like *pachycera* discovered by FASSL.
- hampsoni*. **E. hampsoni** Dgn. (54 e). Forewings of a paler red-brown, with 5 dark transverse bands. Abdomen purple pink, its anal part narrowly banded black. Peru.
- superba*. **E. superba** Drc. (54 b). Of the habitus of an *Amastus*; forewings similar as in *hampsoni*, but at the base a thick, blackish-brown spot, the abdomen more abundantly and more broadly banded black. Mexico and Central America.
- meridionalis*. **E. meridionalis** Rothsch. (54 b) resembles the preceding; bands of forewings likewise as in *superba*, but the colouring ochreous-yellow, instead of the black basal spot some dots and the abdomen yellow instead of pink, the black bands incomplete. São Paulo (Brazil).
- sebrus*. **E. sebrus** Drc. (54 b) is much smaller than the preceding, the forewings more dull orange than ochreous-yellow, the marginal area proximally bordered by an oblique shade proximally defined by black. Beneath the forewings are light yellow-coloured, the marking above only little shining through. South Brazil and Peru.
- hermia*. **E. hermia** Cr. is still smaller (40 mm). Forewings yellow, densely speckled brown; a yellow band marked with red at the base is connected with a yellow antemedian spot at the proximal margin, distally with a crooked brown line; in the cell-end a square spot, a postmedian macular band from the costa to the proximal margin before the anal angle; in the distal area some isolated spots and in the apex 2 coherent spots. Hindwings semi-diaphanous, the proximal area and marginal band rosy-red. Colombia and Surinam to South Brazil.

E. pyrosticta *Hmps.* (= *hermia* *Hmps.* nec *Cr.*) (53 i) resembles both *hermia* and *conspersus*, but it is much smaller, with an orange abdomen banded black, and in the basal part covered with vermilion hairy fleece, thus like *conjuncta*; the forewings, however, are like those of *conspersus* which, however, has a unicolorously golden yellow abdomen without any distinct black bands. The hindwings are again tinted brighter rosy-red, as in *conjuncta*. South Brazil, near Rio, in the Organ Mountains, rather rare. *pyrosticta*.

E. conspersus *Wkr.* (54 c). Forewings yellowish violettish-grey; the whole basal area, a broad median band, a laciniform spot on the costa before the marginal area, and a row of spots through the apical area are *conspersus*.
yolk-coloured, strewn with scarlet. Hindwings whitish, diaphanous; abdomen with some blackish belts, of which those on the rings 1 to 5 are present only on the sides, whilst in the middle of the dorsum they are covered by orange-yellow hair. Panama to Brazil and Bolivia.

E. conjuncta *Rothsch.* (54 c). Larger, similar, but the basal area is here flown together with the discal spot, so that the whole forewing is orange-yellow as far as beyond the middle. Venezuela, South Brazil. *conjuncta*.

E. melanoplaga *Hmps.* (54 c). Size of the preceding; forewing whitish violettish-grey with 5 brown transverse bands bordered with dark, and large brown spots at the base and behind the cell-end; hindwings dirty white with a dark median luna and a greyish-brown distal band close in front of the border. Costa Rica to Ecuador. — Specimens from the Rio Songo deviate from those from the Volcano Irazu and from HAMPSON's figure (Ecuador-specimen) by the dark bands being several times confluent in the distal part of the forewing and by the distal band of the hindwing being broader. This constantly varying form may be denominated: **amarua** *form. nov.* (54 c). Apparently not very rare. The species somewhat resembles *Opharus decrepidoides* (57 c) and its allies. *melanoplaga*.

E. atriceps *Hmps.* (54 c) resembles certain *Halisidota*, such as *andensis*, *argentata* or *caryae* (59 a, b) by the pointed shape of the forewing and the chains of lustrous white oval spots. From Colombia and Peru. *atriceps*.

E. immanis *Edw.* (= *jacca* *Drc.*) (54 d). Size and approximate shape of *atriceps*, but dust-grey, the forewing with nebulous bands dusted dark at the base, before the middle and in the distal third. Hindwing with a whitish basal half; sides and apex of abdomen light yellow. Mexico and Central America, as well as Peru. *immanis*.

E. jonesi *Rothsch.* (54 d). Head, thorax and forewings monotonously dark van Dyke-brown, only at the cell-end a blackish punctiform shade. Hindwing the same, in the middle whitish diaphanous. Abdomen dull yolk-coloured, with dorsal and subdorsal rows of black transverse dots. South Brazil (Santo). *jonesi*.

E. intensa *Rothsch.* (54 d) resembles the following species, but it differs by the absence of a marginal band in the hindwing, which is distally only somewhat darkened, as well as by the abdomen being yellowish-brown with faintly darker segmental indentations and a dull yellow venter, whereas in *dryas* it is above orange-yellow with 2 subdorsal rows of spots, beneath black. Amazon (Fonte Boa). *intensa*.

E. dryas *Cr.* (= *basipennis* *Wkr.*, *fimbria* *Mschlr.*) (54 e). Extremely variable, but the forewing is always dark sooty-brown, finely strewn with whitish, with a light dot on the transverse vein. Round the latter there may be a spot composed of small light scales, or a small twin dot next to it. The hindwing is in the proximal half light diaphanous whitish-yellow, sometimes quite hyaline, sometimes intensely tinted yellow. Abdomen yolk-coloured with a black apex and two rows of subdorsal punctiform spots in the posterior half. — In ab. **erythrinovertex** *Strd.* the abdominal dorsum and the ring round the neck, being otherwise mostly light yellow, are rosy red; this is, however, not a geographical race, but specimens with red bodies occur in some districts beside such with a yellow dorsum, e. g. near Villavicencio in Colombia. Widely distributed and common, from the West Indies and Central America to South Brazil and Bolivia. — **omissus** *Rothsch.* is a large, blackish form, with a broad dark marginal band of the hindwing. The bases of the shoulders, anterior chest and hips are tinted purple, so are the stripes of the forewings beneath. From Oxapampa. — K. JORDAN has examined the male genital organs and ascertained numerous differences among the ♂♂ of *dryas*; it does not seem, however, that they invariably coincide with the variations mentioned above in the exterior of the butterflies. Such forms, separable only anatomically, are: *megalobus*, *tupus*, *hora*, *najas*, *dimidiata*, *coccina*, *erubescens*, all of which were established by K. JORDAN, as well as *subtilis* *Btlr.* — The butterflies come to the lantern only late in the evening, but also the ♀♀. *dryas*. *erythrinovertex*. *omissus*.

E. disciplaga *Wkr.* (= *breviuscula* *Wkr.*, *aperta* *Edw.*) (54 d) greatly resembles the preceding, but the forewings are lighter, more chestnut-brown; hindwings dirty yellowish-white; in the ♂ the brown marginal band extends from the apex little beyond the middle, in the ♀ the hindwings are browner. Abdomen yolk-coloured, the middle part of the dorsum of the abdomen covered with blackish hair, in the terminal part spotted black. México, Central America and Colombia. *disciplaga*.

E. terranea *Rothsch.* is almost the size of the following, head, body and forewings are dark reddish-brown, the latter are densely watered light, with a small whitish dot at the cell-end, like in *dryas* (54 e). The hindwings are yellowish-white, the veins and marginal area tinted red-brown, beneath in the costal area reddish brown. Peru. *terranea*.

- thraikilli*. **E. thraikilli** Schs. (54 d) has the size and shape of a medium-sized *dryas*, but the forewings are more distinctly watered yellowish-brown, and the hindwing is in the distal half tinted rosy-red, without a dark marginal band. The body is of a bright ochreous-yellow, marked blackish-brown, the tegulae showing one thick black dot each, the patagia being quite blackish-brown with an orange-yellow proximal margin. Abdomen banded black. Mexico.
- systron*. **E. systron** Schs. (54 d) from Paraná is smaller and quite dark brown, with a collar finely edged with yellow, the abdomen posteriorly golden yellow, the segments margined dark; on the forewings there are some dispersed light dots; the hindwings are lighter smoky greyish-brown.
- colombiana*. **E. colombiana** Roths. (54 c) has unicolorously light yellowish-red forewings with a yellowish-white costal margin; in the cell and discal fold near the border a dull, dark streak. Hindwings diaphanous white. FASSL discovered it on Mount Tolima in Colombia.
- sarcochroa*. **E. sarcochroa** Dgn. (54 e) is very closely allied to *colombiana*, but the ground-colour of the forewings is more flesh-coloured, from which the name of the insect is derived. Also the hindwings are distally flesh-coloured. Like *colombiana* from Mount Tolima in Colombia.
- ochrota*. **E. ochrota** Hmps. (54 e) is the size of the preceding and has about the same colour of the forewings, but the hindwings are not diaphanous white, but dull greyish, with a rosy distal hue. The abdomen is yolk-coloured, with black bands. Colombia to Bolivia and Peru.
- umber*. **E. umber** Cr. Blackish-brown, hindhead and patagia with yellowish-red-orange spots; abdomen above orange, the margins of the segments and the hair towards the base of the abdomen brown. Hindwings of a rather much lighter brown. 70 (♂) to 86 (♀) mm. Surinam and Panama.
- castanea*. **E. castanea** Roths. (54 e) is much smaller than *umber*, almost quite unicolorously dark brown, but a slightly prominent, darker nebulous stripe defines proximally the marginal area of the forewing, a feeble darkening resting above the cell-end and hindwing as well as abdomen are lighter towards the base. Peru.
- hades*. **E. hades** Drc. (54 e) has the size and approximate shape of the preceding, but it is quite unicolorously deep blackish-brown with an orange-yellow apex of the abdomen. Likewise from Peru.
- atrata*. **E. atrata** Fldr. (54 f). This species initiates a series of almost black butterflies, and it is doubtful whether all that have been described as distinct species should remain or rather be regarded as vicarious forms of few species. In *atrata* the head and collar, the two first abdominal rings and two bands before the black terminal part of the abdomen are of a bright orange-yellow. These two dorsal bands may be so broad that the whole abdomen turns orange except a saddle-spot and the two last segments above. Tegulae and patagia show one thick black dot each; the middle of the hindwing is hyaline, traversed by thick black veins. From Colombia and Ecuador to Peru and Bolivia. The figured specimen from Pozuzo. — **E. felderi** Roths. (54 g), likewise from Peru, shows the orange ring of the base of the abdomen narrower, that before the apex, however, much broader, the hyaline area in the middle of the hindwing reduced.
- subterra*. **E. subterra** Roths. (54 f), likewise from Peru, but from a different district, as the preceding, has the abdomen above quite black except the narrow ring at the base, the sides and apex laterally and beneath; above the apex is also black.
- atrobrunnea*. **E. atrobrunnea** Roths. (54 f). Larger, with broader wings, head and collar orange, as well as the abdomen at the base and on the posterior segmental indentations. Hindwings dark brown, without the hyaline discal area. Venezuela.
- terraoides*. **E. terraoides** Roths. (54 f) from Peru and Bolivia is almost like *atrata*, but the dorsum of the abdomen is not yellow at the base; the hyaline spot in the hindwing only reaches about the middle. Perhaps a form of the following.
- terra*. **E. terra** Drc. (54 f) entirely resembles *terraoides*, but the abdominal dorsum laterally with small yellow dots, the hyaline part of the hindwing extends on the median beyond the middle of the wing. Peru and Bolivia. We figure it from the Rio Songo.
- chimaera*. **E. chimaera** Drc. (54 g) from South Brazil and Paraguay greatly resembles the preceding, but the head and collar are not yellow, but the vertex and patagia only show yellow dots, the abdomen is only laterally spotted yellow, the whole basal half of the hindwing white.
- fuliginosa*. **E. fuliginosa** Roths. (54 g). The whole body and forewings monotonously blackish-brown; the hindwings, however, quite white except the faintly brownish apical part. Peru.
- carbonaria*. **E. carbonaria** Dgn. (54 h). Body and forewings coloured like in *fuliginosa*, but the hindwings of a dirty earth-colour. Bolivia and Peru.

E. pallidicosta Wkr. (54 h). Above quite dark olive-brown, only the costal margin quite narrowly *pallidicosta*. sulphureous. Beneath the hips are yellowish-brown, the abdomen white. The ♂ has a straight border of the hindwing, so that it almost appears triangular. From Colombia (Pacho, Mount Tolima) through Venezuela as far as Bolivia and Peru.

E. flavicosta Drc. (54 g) has entirely the shape of the preceding, but above the head and the anterior edge of the thorax (are yellowish-white, and on the forewing the whole costal area is lighter, as well as the median and a parallel stripe in front of the darkened margin. The venter is likewise white. Reported from Peru, the figured specimens, however, are from Orosi in Costa Rica, from the Volcano Irazu, at an altitude of 1200 m.

E. lavinia Drc. (= *lavinea* Rothsch.) (54 g). Here the body and forewings are also blackish-brown, but the latter have a broad, sulphureous costal stripe and on the transverse vein a fine, yellow V. Hindwings white, with a brownish apical part and border. Peru.

E. bicolor Mssn. (54 f). Body and forewings sooty blackish-brown, the forewing (in the type figured here) with a deep yellowish-brown costal stripe, the hindwings diaphanous whitish. Ecuador, Peru.

E. barnesi Schs. (54 h). Body and wings white, the abdominal dorsum tinged orange-yellow. From Cuba, where the species is apparently rare.

E. insula Dgn. (54 g). Head and thorax sooty yellowish-brown, abdomen brownish-grey, towards the apex tinged dark brown, with a yellow anal tuft. Forewings yellowish-brown with slightly darker veins. Hindwings unicolorously dull dark brown. Loja (Ecuador).

E. tricyphoides Rothsch. (54 h). Smaller, above likewise dull dark brown, but the head above bone-white, abdominal end laterally, the last segment also above yolk-coloured. Forewing with a black dot at the cell-end, and an undulate, W-shaped, dark antemarginal line. Guiana and Amazon.

E. phantasma Schs. (54 h). Smaller and paler, thorax and forewings light earth-grey, with a brownish apical area, hindwing whitish, at the costal margin and apex broadly greyish-brown; inner-marginal area and abdomen honey-coloured. Guiana.

E. deceptura Drc. (54 h). Size of the preceding, the forewings of a purer greyish-brown, and the hindwings all white. Head above yellowish, thorax greyish-brown, abdomen dark brown, at the base whitish and at the end yellow. Peru.

68. Genus: **Pelochyta** Hbn. (*Sontia* Wkr.)

The 16 species united to this group are mostly medium-small, unicolorously brown or yellowish insects without any peculiarities. In their range they agree with the *Elysius*. They also have a strong proboscis, but mostly also large palpi obliquely bent up, with a distinct terminal joint resting on a long and thick middle joint ♂ antennae with strong, in the ♀ with short pinnæ in a double row. Like in *Elysius* the abdominal dorsum is in the basal half densely covered with hair. In the forewing the 2nd subcostal vein rises before the upper cell-angle, the upper median vein before the lower cell-angle. No areola; transverse vein angular. The lower median vein only rises in the middle of the wing from the cell-wall. In the hindwing all the veins are present; they are often rather small. — Of the larva I only know SEPP's figure of *P. arontes* (= neuroptera Sepp). It has unpaired, stunted brushes across the dorsum, on the 3rd and 9th segment long pencils and on the 4th ring a cap-shaped hair-pad. It thus recalls some Syntomid larvae, such as those of *Episcepsis thetis* etc. Type: *P. arontes*.

P. atra Rothsch. (55 a, b). ♂ blackish-brown, frons and tegulae with yellowish-red dots, bases of wings black dots. Abdomen beneath white. ♀ more reddish-brown, frons yellowish; much larger than the ♂. Peru.

P. nigrescens Dgn. (55 a) is quite similar, the ♂ somewhat lighter (the ♀ is not known), upper head, collar, metathorax, and dorsum of abdomen purple except a dark middle stripe. Colombia, Ecuador, Peru and Bolivia.

P. haemapleura Dgn. (55 a) is almost entirely like *nigrescens*, the red of the head and thorax more covered by brown hair, the sides of the abdomen narrower red. It might be a small ♀ of *nigrescens*. Colombia.

P. misera Schs. (55 a). Wings like in *haemapleura*, but the head and collar yellowish-brown, on the vertex and each of the tegulae one black dot each. Apex of abdomen laterally orange. Costa Rica.

P. bicolor Rothsch. (55 a). Wings dark chestnut-brown, like the body, and the head above with purple dots, and the dorsum of the abdomen posteriorly tinted red. Peru.

P. brunnescens Rothsch. (55 a) resembles *bicolor*, but it is larger and of a somewhat lighter brown, the hindwing in the cell somewhat diaphanous, abdomen laterally orange, with black lateral dots. Panama to Peru.

- dorsicincta*. **P. dorsicincta** *Hmps.* (= *colombiana* *Rothsch.*) (55 a). Wings broader, lighter brown, particularly the hindwings. Head and prothorax dotted black, abdomen posteriorly banded yellow; frons and neck sometimes yellowish red. Colombia.
- albipars*. **P. albipars** *Hmps.* (55 b). Almost exactly like the preceding, also the black dots on the forehead and prothorax, hindwing except the apical part lighter, but the abdomen posteriorly without the yellow transverse bands. Peru.
- umbrata*. **P. umbrata** *Hmps.* (55 c). Sooty blackish-brown, in the cell and basal part of the hindwing lighter patches. Head and prothorax, like in the preceding, dotted black, abdomen yellowish-grey with black transverse bands, and the basal part covered with dark hair. Bolivia, discovered by O. GARLEPP.
- suffusa*. **P. suffusa** *Joicey*. As large as *umbrata*, but the forewing red-brown with a grey antemedian shade and an oblique postmedian one, as well as with a narrow antemarginal shade; hindwings pale red-brown with yellow at the proximal margin, and towards the base lighter. Abdomen above orange, posteriorly with blackish macular bands. Peru.
- cervina*. **P. cervina** *Edw.* (55 c). Head and body yolk-coloured, prothorax with fine black dots, abdominal dorsum posteriorly with jet-black, sometimes interrupted transverse bands. In typical ♂♂ the hindwings are orange-yellow. — In ab. **guatemalae** *Strd.* from Guatemala they are brown, with a yellow costal and proximal area. — In ab. **brunnitricha** *Strd.*, lying before us from Orizaba (Mexico), the hindwings are black with a greyish-blue reflection. The ♀ is more ochreous. Mexico and Central America.
- cinerea*. **P. cinerea** *Wkr.* (55 c) resembles the preceding in its size and shape, but the wings are more ashy-grey, and the thoracic dorsum is covered with greyish-brown hair. Prothorax and bases of the wings yellowish with fine black dots; abdomen above with black transverse bands. — ab. **lystra** *Drc.* is less unicolorous, forewings more violettish-brown, hindwing towards the margin more intensely brown; from the Chiriqui. — The species is not rare and extends from Panama to Bolivia and Paraguay.
- pallida*. **P. pallida** *Dgn.* (55 b). Smaller, body and forewings pale brownish ochreous-yellow, with dull dots on the upperhead and prothorax, those at the bases of the wings being absent. Abdomen greyish-brown with black lateral punctiform spots; hindwings diaphanous whitish. Colombia and Peru.
- arontes*. **P. arontes** *Stoll* (= *neuroptera* *Sepp*, *degenera* *Wkr.*) (55 b). Head, prothorax and base of forewing with black dots, abdomen yellowish-brown, at the base covered with dark hair, across the dorsum 2 rows of black dots, which are sometimes confluent on the rings 1 to 4. Forewings almost violettish-brown with blackish veins, hindwings tinted dark brown. — Larva iron-grey with a yellow anterior part and a red-brown dorsal stripe as well as very conspicuous hair. The whole larva is covered with blackish-grey, laterally also whitish hair. Behind the 3rd ring a cap-shaped transverse pad of velvety-black hair; before it two white pencils of more than one centimeter's length, between them 4 ear-shaped hairs. Across the dorsum similar brushes as in the larvae of *Orgyia*; before the anal end again long white pencils with a grey one between them, and oar-shaped hairs on the rings 10 to 12. It lives on *Inga vera*, changes in a grey, oviform web intermixed with hair into a red-brown pupa creeping out after about 12 days. Central America to Bolivia and Paraguay.
- affinis*. **P. affinis** *Rothsch.* (55 d) is smaller than the preceding, body ruddle-red, the black dots on the head, prothorax and base of forewing fine, but distinct. Forewing at the base pale reddish, otherwise dark red-brown with a blackish transverse vein; hindwing in the proximal area lighter. Ecuador.
- albotestaceus*. **P. albotestaceus** *Rothsch.* (55 e). One of the largest and lightest *Pelochyta*. Colouring monotonously dirty whitish-grey. Of the dots there are on the thorax only one on each patagium, and some four or five are scattered in the basal half of the forewing. At the cell-end a brownish C-spot. Hindwing at the apex somewhat brownish. Venezuela.

69. Genus: **Agoraea** *H. Schöff.*

This genus contains about more than a dozen of very small butterflies, which, however, in spite of their shape, show already a resemblance with the *Halisidota* being dealt with later on. Proboscis strong (when extended more than the length of the thorax), palpi rising obliquely, the middle joint sometimes very long, the terminal joint neither stunted. Body sometimes slender, sometimes compact, hairing smoothly appressed; the base of the abdomen is not covered with a fleece of woolly hair, as in the *Pelochyta*. Cell of forewing rather broad, mostly with a distinct proximal vein; no areola. Hindwing with all the veins. The wings are thinly scaled, sometimes hyaline, as in the following genus, without any remarkable marking; the species, however, are easily distinguished by the colouring and marking of the body.

- minuta*. **A. minuta** *Schs.* (55 e). Wings hyaline, head white, thorax dirty yellow, abdomen orange with a dorsal row of black dots. Mexico to South Brazil.

A. ockendeni *Rothsch.* (55 d) from Peru is almost exactly the same, but the abdomen without the *ockendeni* row of black dots.

A. citrinotincta *Rothsch.* (55 e) has somewhat longer and narrower forewings, the veins more distinct, *citrinotincta* head and body monotonously yolk-coloured. Colombia and Venezuela.

A. klagesi *Rothsch.* (55 d) has the veins still more prominent and distinct than *citrinotincta*, but *klagesi* dorsal dots on the abdomen like *minuta*. Amazon (Fonte Boa).

A. longicornis *H.-Schäff.* (= *venosa* *Wkr.*, *emendatus* *Edw.*, *schausi* *Rothsch.*) (55 d). Antennae very *longicornis* long, as long as in *citrinotincta*; wings hyaline, faintly brownish, abdomen orange, in the basal part brown with a dull dorsal stripe, the terminal half with black dorsal dots. Head orange. Hindwings whitish. Mexico to South Brazil, not rare.

A. phaeophlebia *Hmps.* (55 d) from Venezuela, is much larger, with broad, hyaline wings tinted *phaeophlebia* yellowish at the margins; head, thorax and abdomen yolk-coloured, without dorsal dots.

A. atrivena *Dgn.* (55 d) is still larger, all the wings with black veins and internerval streaks. Abdomen *atrivena* orange, basal part blackish. Colombia.

A. inconspicua *Schs.* (55 d) from Costa Rica has a sooty black body and wings, only the upperhead *inconspicua* and the apex of the abdomen are orange-yellow.

A. boettgeri *Rothsch.* is larger than *inconspicua*, wings tinged more brownish, beside the head also the *boettgeri* tegulae and patagia, as well as the last 2 or 3 abdominal rings are orange-yellow. Peru.

A. semivitrea *Rothsch.* (= *pellucida* *Hmps.* n. *Sepp*) (55 e). Forewings more pointed than in the *semivitrea* preceding species; head and thorax creamy-white, tinged with yellow, patagia with a fine black median stripe. Abdomen orange with a series of dorsal dots; in the forewing there is a blackish dot on the transverse vein and a dark comma-shaped spot before the rise of the lower median vein. Panama to Surinam.

A. nigrostriata *Rothsch.* (55 e) is easily recognized by the black lines marking the upper cell-wall and *nigrostriata* still more distinctly the lower one. Thorax yellowish with fine black longitudinal lines, abdomen yolk-coloured. Tucuman in North Argentina.

A. rectilinea *Burm.* (55 d). Somewhat larger, forewings creamy yellow with a thick black line proceeding from the base along the median as far as the middle of the border. On the thorax only one dark middle streak is distinct; abdomen yolk-coloured, at the base whitish. South Brazil.

A. ruficauda *Rothsch.* (55 f) is rather similar to *longicornis*, but the abdomen above purple-red, therefore not to be mistaken for another species. Minas Geraes.

70. Genus : **Bituryx** *Wkr.*

On the whole very much like the preceding genus, chiefly distinguished from the *Agoraea* by the short straightly porrect palpi, as well as by the 2nd subcostal vein not branching off from the upper cell-wall, but only behind the cell-angle. Only few species are known, not differing from the *Agoraea* in their habits.

B. lanceolata *Wkr.* (55 e) is the largest species; head, thorax and forewings milky-white, hindwings *lanceolata* dirty white; abdomen scarlet with black dorsal and lateral dots. From Hayti.

B. diversipes *Wkr.* (= *rhodogaster* *Snell.*). Beside *lanceolata* the only *Bituryx* with a red abdomen, *diversipes* but smaller than *lanceolata*, and the forewings not milky-white, but dull diaphanous whitish with brown veins. Venezuela.

B. venosata *Wkr.* (55 e) is quite similar as *diversipes*, but the abdominal dorsum yolk-coloured, *venosata* with a white terminal joint; in the ♀ the dorsal dots are often absent. Mexico and Central America.

B. grisea *Dgn.* (55 e). Forewing and apex of the hindwing tinged brownish; before the border of *grisea* the forewing a row of black dots; otherwise almost exactly like the preceding. Colombia and Peru.

B. intacta *Wkr.* (55 e). Thorax and wings white, but head, collar and abdomen bright orange-yellow. *intacta* Venezuela and Amazon.

B. pellucida *Sepp.* Quite similar to *intacta*, but much smaller; the thorax between the yellow collar *pellucida* and the orange abdomen not white, but tinged brown, and the forewings light greyish-brown with a violet hue and more distinctly dark veins. Venezuela and Guiana.

71. Genus: **Arctagyrtia** Hmps.

This genus was established in 1901 for one of the smallest species having been before inserted in the Syntomid genus *Agyrtia*. At once recognizable by the reduced subcostal system of the forewing showing only 3 subcostal veins. Proboscis strong, palpi very thin. Wings rounded.

- nana*. **A. nana** Wkr. (44 b). Black, all the wings with a hyaline centre and black margins which are broadest in the apical part. Amazon. The species is apparently not common, but it is also perhaps easily overlooked on account of its small size (expanse scarcely 2 cm) or also for its superficial similarity with numerous Syntomids such as *Euagra cerymica* (23 h), *fenestra* (23 i), *Teucer carmania* (20 a) etc.

72. Genus: **Ischnocampa** Fldr.

The two dozen species belonging hereto mostly approximate the following *Opharus*, only some being considerably different, such as *I. nigrivena*, in which we may presume a mimicry of other genera (*Pachydota striata*, 55 i). Proboscis strong, palpi, however, slender, delicate, with a comparatively long, porrect terminal joint. Antennae doubly combed, in most of the species not so long as in the allied *Opharus*, *Amastus* etc. In the forewing the 1st subcostal vein rises before the cell-end, from the angle itself rises the footstalk of the 2nd to 5th, from the same place with the upper radial. From the lower cell-angle rise the two other radials and the upper median vein likewise from one and the same spot. In the hindwing all the veins are present.

- griseola*. **I. griseola** Rothsch. (55 f), the smallest species, is only the size of an *Agoraea*. Wings brown, densely powdered with an ashy grey, forewings with a black dot in the cell-end and a curved antemarginal transverse stripe sending forth on the submedian an obtuse tooth turned inward. From Jamaica, rare.
- admata*. **I. admata** Rothsch. (= *lithosioides* Rothsch. p. p.) (55 g) is somewhat larger than *griseola*, the antemarginal stripe not curved, but through the middle extends another dark transverse band, and a third, curved one is before the middle. Venezuela.
- lithosioides*. **I. lithosioides** Rothsch. (55 g). Forewings more ochreous, the 3 transverse bands are represented by curved, indistinctly defined nebulous stripes. Abdominal end orange-yellow. From Rio de Janeiro, rare.
- celer*. **I. celer** Schs. (55 f). Forewings more reddish-ochreous; the distal transverse stripe forms a longish W, the middle one being S-shaped, the proximal one interrupted on the submedian fold; hindwings dusted with grey. Likewise from South Brazil (Novo Friburgo).
- sordida*. **I. sordida** Fldr. (55 h). Forewings ochreous, very much strewn with black. Marking very much like that of the preceding; with a black dot in the cell-end, a W-shaped antemarginal stripe and a postmedian transverse shade only distinct at the proximal margin. Size of the preceding. Colombia, Bolivia and Peru.
- sordidior*. **I. sordidior** Rothsch. (55 f). Only the punctiform shade at the cell-end and the nebulous antemarginal stripe are distinct, otherwise the forewing is reddish-ochreous, striated and strewn with black. Hindwing at the border very brownish, otherwise diaphanous white; apex of abdomen orange-yellow. Peru.
- floccosa*. **I. floccosa** Rothsch. (55 g). Like *sordidior*, but the ground-colour of the forewing more greyish-yellow, and most purely and brightly covered with striae at the border, distally to the transverse stripe, proximally to it, however, very much with dark striae. Peru.
- ignava*. **I. ignava** Dgn. (55 f). Wings much longer than in the preceding, body slim. Forewings reddish ochreous; a dark marginal nebulous stripe, an antemarginal one, and a postmedian one being somewhat curved. Colombia.
- perirrorata*. **I. perirrorata** Hmps. (55 f). Forewings ochreous-yellow, densely dusted with blackish-brown, the small scales before the apex at the costa and right through the middle condensed to nebulous bands. Hindwings diaphanous bluish-white, the margins and apical part brownish. Thorax and abdominal end yellow, dorsum of abdomen blackish. Bolivia.
- remissa*. **I. remissa** Dgn. (55 f). Wings white, the margins ochreous-yellow, the veins dark; in the forewing at the cell-end a yellowish-brown demi-band and before the distal margin a transverse row of blackish streak-shaped and cap-shaped spots. Venezuela.
- hemihyala*. **I. hemihyala** Hmps. (= *tolimensis* Rothsch.) (55 g). Body blackish-brown with a yellow apex of the abdomen. Wings hyaline, the margins of the forewings yellowish-brown: in, below and behind the cell dark dots. Colombia to Peru.

I. achrosis Dgn. (55 f). Forewings bone-white, at the margins broadly tinged yellow; also the head *achrosis*. and body pale yellow; above the anal angle of the forewing some small, blackish antemarginal streaks situate in a faint subterminal shade. Loja in Ecuador.

I. obscurata Hmps. (55 g) pale brownish-yellow, forewing dirty ochreous, the marginal part of the *obscurata*. purest tinge. Before the apex at the costa a brown shade; hindwings somewhat diaphanous whitish, at the border dark ochreous. Colombia and Peru.

I. mamona Dgn. (55 h). Yellowish-grey, abdomen darker with a yellow apex. Forewing with a dark *mamona*. dot in the cell and blackish streaks in the spaces between the veins before the margin. Hindwing with a darker marginal shade, being broadest at the apex, but not reaching the anal angle. Loja (Ecuador).

I. nubilosa Dgn. (55 h) is very closely allied to *mamona*, but it has a black dot also in the cell of *nubilosa*. the hindwing. The colour is a more reddish tinge. Likewise from Loja.

I. discopuncta Hmps. (= *tovia* Dgn., *barbata* Drc.) (55 g). Greyish-brown; forewing in the cell *discopuncta*. with lighter stripes, on the median, from the base, a dark, longitudinal, nebulous streak crosses the wing; in the internerval spaces brown dots. Hindwing with a brownish border, particularly in the apical part, otherwise diaphanous whitish. Bolivia and Peru.

I. albiceps Dgn. (55 h). Greyish-brown, the forewing covered with dark sepia-brown small streaks, *albiceps*. the hindwing lighter in the disc. Thereby the colouring of numerous other butterflies, such as *Opharus*, *Elysius*, *Pelochyta* etc. is produced; but the species is at once discernible from all of them by the head being white above and by a white spot on the mesothorax. Colombia, found by FASSL.

I. lugubris Schs. (55 b,k) greatly resembles *albiceps*, but the forewing is suffused with a more leaden- *lugubris*. grey tinge, the head above dark brown, not white, and on the thorax no white spot. South Brazil.

I. tristis Schs. (= *dolens* Drc.) (55 g). Almost exactly like *lugubris*, but the tegulae and patagia *tristis*. whitish, the hindwing in the disc of a clearer, lighter tinge, the abdomen with white sides parted by a dark longitudinal furrow. Mexico, Central America, Venezuela and South Brazil.

I. ferrea Dgn. (55 h). Body slender, antennae very long, almost the same as in *Opharus*. Forewing *ferrea*. light brown, with dark margin and thick, blackish-brown veins; hindwing diaphanous white, at the border darker. Colombia, found by FASSL.

I. mundator Drc. Similarly coloured as *tristis*, but much larger (66 mm). Recognizable besides by the *mundator*. whitish apices of the patagia; also the abdominal sides are spotted whitish. Costa Rica.

I. styx Jones (55 h). Considerably smaller than *mundator*, which it otherwise resembles, but the *styx*. forewing more umbra-brown, the hindwing not diaphanous white in the disc as in *mundator*, but a little lighter than the border. Trinidad and Santos in South Brazil, rare.

I. nigridorsata Schs. (55 e). Body yolk-coloured, thorax marked orange, above the middle of the *nigridorsata*. abdomen a broad, blackish saddle-spot. Wings creamy-white with dark veins, the hindwing tinged brownish. Peru.

I. nigrivena Schs. (55 h). Body golden-yellow, wings dark yellow, the forewing in the costal area *nigrivena*. milky-white; all the veins (except the discocellulars) marked with a thick blackish-brown; also the vein in the cell thickly black. The largest species of the genus; in some districts of Bolivia common.

Note: according to recent investigations by HAMPSON, *Desmotricha uniformis* Hmps. also belongs to this genus (p. 153, t. 23 c), having hitherto been dealt with as a Syntomid.

73. Genus: **Pachydota** Hmps.

About a dozen forms of a robust, in the ♀ clumsy structure, being divided into two groups. The first only contains 2 species and so exactly approximates *Ischnocampa nigrivena* in the colouring, that it is often mistaken or confounded with it in the collections. The second group contains a number of very closely allied species. Formerly still more forms were distinguished, but some have been eliminated as synonyms. The *Pachydota* have a strong proboscis, rather short, steeply rising palpi with a rudimentary terminal joint, a very broad forehead, doubly combed antennae with rather short teeth, a broad thorax; in the forewing the 1st and 2nd subcostal vein have a common footstalk. The two groups differ beside the colouring, above all by the first group having a round apex of the forewing, whilst the ♂♂ of the 2nd group show the distal margin indented

below the apex of the forewing. Although the numerous, very closely allied forms of this group are probably only partly distinct species, they are still enumerated separately here, since they have since been kept separate in the catalogues.

1. Colouring unicolorously yellow.

- striata*. **P. striata** Dgn. (55 i). Of a bright dark yellow, forewing with a white longitudinal stripe above the upper cell-wall and above the base of the proximal margin; veins of the forewing black except the transverse vein, abdominal dorsum with a black saddle-spot. From Colombia to Bolivia, in some places common. Not rare.
- nervosa*. **P. nervosa** Fldr. (55 i) is very much like *striata*, but the veins of the forewing finer black, and on the dorsum of the abdomen no black saddle-spot. Colombia to Bolivia and Peru. Not rare.
2. Forewing violettish-grey with dark bands; head above white.
- affinis*. **P. affinis** Rothsch. (55 i), from Popayan and Merida in Venezuela, has (in the ♀) quite unicolorously dark brown hindwings. Abdomen orange with a dark dorsal spot on the 1st, 2nd and 3rd ring. — **palmeri** Rothsch. is larger and the ♂ has the whole hindwing almost as far as the fringes diaphanous white, much farther than the ♂ of the typical *affinis*. San Antonio in West Colombia.
- drucei*. **P. drucei** Rothsch. (= *josephina* Schs.) (55 i). The dark dorsal spot on the abdomen extends as far as the 5th ring and is continued in minute spots to the end of the abdomen. Mexico, Colombia.
- iodea*. **P. iodea** H.-Schüff. (56 a) is very similar to *drucei*, abdomen above in the ♂ quite black except the margins. Hindwing quite blackish-brown, only the inner-marginal area yellowish. Jamaica, Mexico to Guiana.
- rosenbergi*. **P. rosenbergi** Rothsch. (55 k) is the smallest species; hindwing only at the base white, abdomen with yellow lateral spots, otherwise the abdomen blackish-brown. Ecuador.
- peruviana*. **P. peruviana** Rothsch. (55 k). Abdomen with a black belt (rings 2 and 3) being extended yet on the middle of the dorsum of ring 4, the posterior half of the abdomen again yellow, with narrow dark segmental margins; hindwings (in the ♂) whitish diaphanous, apex and inner-marginal area brown. Border of the forewing straight, not indented. Peru.
- albiceps*. **P. albiceps** Wkr. (= *inermis* Schs.). Forewing less banded than in the species enumerated so far; abdomen as far as ring 3 dark brown, then yellow with a blackish apex, dark segmental margins and a blackish-brown dorsal spot on ring 3. Panama to Brazil. — In *luciana* Strand from Sa. Lucia, the head is above yellow instead of white.
- ducasa*. **P. ducasa** Schs. (= *palmeri* Rothsch. ♂ nec ♀) (55 k) has the abdomen above quite blackish-brown except the broad golden yellow belt at the base and narrow, small, yellow transverse bands at the end of the abdomen. Hindwing entirely whitish hyaline except the brown apical part and dark dusting on the border and inner-marginal area. Venezuela.
- saduca*. **P. saduca** Drc. is almost exactly like *albiceps*, but with a broad orange belt at the base of the abdomen, like *iodea*, but the latter is without the dark wings in the posterior half of the abdomen. Costa Rica to Bolivia.
- punctata*. **P. punctata** Rothsch. (= *albiceps* Hmps. nec Wkr.) (55 k) is one of the smallest forms with very dark, broadly banded forewings, the abdomen orange-yellow as far as the apex, with but narrow black segmental margins. Described from Surinam; the figured specimen, however, from Mexico.

74. Genus: **Xanthophaeina** Hmps.

This genus is based upon the ♂ of a species entirely unknown to me. The type is in the Oxford Museum and another example is in FELDER's collection in the Tring Museum. According to HAMPSON, the species has a strong proboscis, palpi of medium length the terminal joint not stunted, doubly-combed ♂ antennae with the teeth widened at the ends, a broad, densely haired thorax and rather broad, normally shaped wings. The 1st subcostal vein rises shortly before the upper cell-angle, out of which rises the footstalk common to the 2nd to 5th, from the same spot as the upper radial. The two other radials proceed from the lower cell-angle; close before the latter the upper median vein branches off. Hindwing with all the veins, the discocellulars being angled.

- levis*. **X. levis** Drc. 58 mm; head, thorax and the basal part of the abdomen dark brown with a violet reflection. On the hindwing in the discal area a V-shaped spot is placed in such a way that the ends of the sides are situate below the costa at the beginning and end of the discal area, whereas the lower apex of the V is situate above the middle of the proximal margin. The proximal side of the V is much broader, particularly in its lower part, than the distal one. Posterior half of abdomen orange, the 4th segment above black, the others with a black dorsal dot. Beneath the abdomen is black with rows of yellow punctiform spots. Popayan in Colombia; beneath FELDER's specimen it only says: „Brazil“.

75. Genus: **Pitane** Wkr.

The genus already has the entire structure and character of *Calidota* from which it chiefly differs only by the proboscis being strongly haired in its basal part. Like *Calidota* it has on the forewing a very long and narrow accessory cell produced by the 2nd subcostal vein anastomosing with the bifurcation of the 3rd and 4th, the 2nd palpal joint being long, the terminal joint well developed. The only species known is very characteristically coloured.

P. fervens Wkr. (56 a). Forewings violettish-red with 3 large orange spots in the basal, median, and distal areas; hindwing red with a blackish marginal band. Peru and Bolivia; in the specimen before me from the Rio Songo the orange spots are smaller than in the Peruvians. *fervens.*

76. Genus: **Stidzaeras** Hmps.

Distinguished from the preceding genus by the course of the anastomosis extending from the 2nd subcostal vein to the bifurcation of the 4th and 5th veins, in *Pitane* to the 3rd and 4th. One species was described as *Pitane*, the other, typical one has the venation of the ♂ forewing distorted on account of a scent-apparatus.

P. evora Drc. Shape similar to *Pit. fervens*, size just a little smaller; forewing greyish-brown, the marginal area red-brown, hindwing in the proximal half pale yellow, in the distal half dark brown; head and collar as well as the anterior half of the abdomen yellow, thorax and end of abdomen dark brown. Peru (Pozzuzo). *evora.*

P. strigifera Drc. is somewhat larger, the forewings brown with numerous light transverse striae and a hyaline wedge in the cell. Hindwing with a yellow proximal and blackish-brown distal half. Head and collar as well as the abdomen orange, the latter posteriorly with some narrow black transverse bands. Venezuela. — In the form **ockendeni** Rothsch. the striae of the forewing are obsolete, head and collar are red; from Peru. — The species is at once recognizable by a cuneiform scent-pad filling up the whole cell of the forewing beneath and distorting the wing in such a way that the distal margin is shortened like in some *Tineids* and the veins are crooked in the apical part. *strigifera.* *ockendeni.*

77. Genus: **Calidota** Dyar.

3 dozen forms are known, being placed here and partly attaining a rather considerable size. The colouring is preponderantly grey, brown or blackish; antennae partly very long, proboscis strong, palpi obliquely ascending. The long areola was already mentioned in *Pitane*; the cell of the forewing is broad, the transverse vein angled. In contrast with purely neotropical genera having been dealt with so far, this genus reaches with some species the southern part of the United States. — The genus is, moreover, not homogeneous and contains a group of lank, slender species with broad wings and extremely long antennae, and another group of robust, relatively small-winged forms with a very stout thorax. Only of one of the latter species the larva is known, being provided with radiatingly haired tubercles; of the hair those on the anterior and posterior parts are longer, whilst those on the middle segments are shorter.

C. strigosa Wkr. (= *loqueata* Edw., *cubensis* Grt.) (56 a). As large about as an *Acronicta aceris*, thorax and forewings light grey, marked brownish from dark longitudinal streaks above the middle of the proximal margin and in the distal area. Abdomen vermilion, sometimes with some dorsal dots, oftener without them. Texas, Florida, Cuba, Hayti. — **jamaicensis** Strd. is the form from Jamaica with more distinct black markings of the forewing and the abdomen often shaded dark at the base. — Larva in its early stage variegated, with yellow or salmon-coloured patches, in its grown-up state flesh-coloured brown with a dark dorsal stripe and yellowish-brown hair, those on the anterior and posterior parts being longer. It lives on *Guettarda elliptica* and changes in an oviform web intermixed with hair into a mahagoni-coloured pupa. *strigosa.* *jamaicensis.*

C. rema Dgn. (56 a). Yellowish-brown, tegulae with a black dot, dorsum of abdomen blackish. Forewing with 4 black punctiform spots, of which 1 is in the cell, 1 below it and 2 behind it. Hindwing dusted dark brown, towards the base lighter. South Brazil. *rema.*

C. euchaetiformis Edw. (56 a), from Mexico, is similar, but the abdomen golden yellow with black dorsal dots; the black punctiform spots more numerous in the disc of the forewing. *euchaetiformis.*

C. muricolor Dyar (56 d). Wings diaphanous whitish-grey, without markings, thorax brown, head and ring round the neck yellow, abdomen above buff with dark dorsal dots. Arizona. *muricolor.*

C. paulina Jones (56 b). Body stout and clumsy. Head and thorax dark brown, marked orange; abdomen dark brown, beginning from the 3rd ring with large orange lateral spots almost touching each other near *paulina.*

the apex. Forewings dark brown with darker nebulous dots and larger spots in and behind the cell-end; hindwing lighter, a basal spot in and behind the cell white. São Paulo.

- rubrosignata*. **C. rubrosignata** Weym. (56 b). As large as *paulina*, head, thorax and wings black with a bluish reflection, the forewing with a red costal stripe at the base, and again beyond the middle as far as the apex dark red. Dorsum of abdomen purple-red, at the base covered with black hair. Venezuela.
- palmeri*. **C. palmeri** Drc. (56 b). Slender, with broad wings, very long antennae, almost like an *Opharus*. Head orange, thorax and forewing dark brown, hindwing of a lighter brown with a darker apical part, abdomen orange with black transverse bands. Colombia.
- conspicuus*. **C. conspicuus** Drc. (56 b). Much smaller, head, thorax and forewings dark brown, ring round the neck and abdomen orange, hindwing with a white median part in and behind the cell. Peru.
- leucocorypha*. **C. leucocorypha** Dgn. (56 b). Head above white, thorax and forewing dark brown, hindwing only in the costal and marginal areas dark brown, basal half yellowish-white, with a dark brown, posteriorly narrowed dorsal band, and transverse bands on the 2nd and 3rd rings. Peru.
- gigas*. **C. gigas** Dgn. (56 c). Size of the preceding, but the hindwing without the whitish-yellow basal part. Head dark brown with orange dots; abdomen with transverse bands on all rings. Panamá, Ecuador, Peru, occurring yet at great altitudes.
- similis*. **C. similis** Hmps. (56 c). Somewhat smaller and lighter brown, head above whitish-yellow, dorsum of abdomen posteriorly quite golden yellow, anteriorly only on the sides. Peru and Bolivia.
- gemma*. **C. gemma** Schs. (56 c) is much smaller, but similarly coloured; head and thorax yolk-coloured, marked brownish, abdomen yellow with a dark brown dorsal stripe. Forewing with a black dot in the cell, hindwing in the disc and inner-marginal area lighter. Venezuela and South Brazil.
- albiceps*. **C. albiceps** Dgn. (56 c), very similar to *gemma*, but the yellow thorax anteriorly dotted dark, hindwing brownish only at the border, forewing with a darker cell-end, but without a real black dot in the cell. Venezuela.
- rudis*. **C. rudis** Schs. (56 d). Head and body honey-coloured, thorax marked brown; wings dark brown with a blackish cell-end and veins. Hindwings a little lighter than forewings. Costa Rica.
- morosa*. **C. morosa** Schs. (56 c). Head, thorax and forewing pale greyish-brown, the latter with a dark transverse shade in the middle, behind it hyaline parts. Hindwing dull diaphanous whitish, at the border faintly brownish; abdomen whitish-grey. Peru.
- momis*. **C. momis** Dyar (56 d). Head and thorax whitish, marked dark with a dot on the vertex and tegulae. Forewing light brown with 3 dark dots in the cell-end. Hindwing in the proximal part diaphanous whitish, apical half brown. Abdomen ochreous-yellow with dark dorsal dots. Orizaba (Mexico).
- quadripunctata*. **C. quadripunctata** Schs. (56 d). Quite similar to *momis*, but the dorsal dots of the abdomen more intense, the hindwings quite whitish, only the apex brownish. Costa Rica.
- calosoma*. **C. calosoma** Dyar (56 d). Head, thorax and anterior half of abdomen yellow, marked brownish-red; posterior half of abdomen blackish. Wings dirty diaphanous, yellowish-white, at the cell-end a darker crescent. Mexico. Type in the National Museum at Washington.
- angelus*. **C. angelus** Dyar (56 f). Head and thorax creamy white, marked red, abdomen dark red. Forewing drab with a yellow costal-marginal stripe. Hindwing white. Mexico, discovered by ROBERTO MUELLER.
- albaticosta*. **C. albaticosta** Dyar (56 e). Quite similar to *angelus*, different by the dark violettish-grey head, thorax and forewing. Mexico; discovered by ROBERTO MUELLER.
- zella*. **C. zella** Dyar (56 b). Much smaller than the preceding; head, thorax and forewings dark brownish-grey, hindwings diaphanous white, abdomen flesh-coloured, with dark lateral dots. Discovered in the district of the hot springs in Arizona.
- obscurator*. **C. obscurator** Drc. (= *obscurata* Hmps.) (56 d). Middle and posterior legs very long, also the wings very much extended, forewings yellowish-brown, but densely watered with brown atoms and minute dark spots, as if bestrewed with coarse sand or saw-dust. On the median the dark parts are united to a frequently interrupted longitudinal stripe. Hindwing of a more uniform brown, in the disc somewhat diaphanous. Abdomen dull yolk-coloured with small black transverse spots across the dorsum. Mexico and Central America, in some districts common.

C. phryganoides Wkr. (56 e). Smaller, just as coarsely strewn and striated as *obscurator*, but the marking is already arranged to a light, curved antemedian band, a postmedian undulate line, and an obsolete, undulate antimarginal line. Hindwing diaphanous brownish, towards the apex darker. Dorsum of abdomen yellow, spotted black. Mexico. *phryganoides*.

C. divina Schs. (56 e). Size of *obscurator*, more brightly marked, particularly distinct a costal transverse bar in about $\frac{1}{4}$ of the costa, an antemedian costal spot reaching yet the cell, a postmedian undulate stripe dissolving distally, and an antimarginal dentate stripe; recognizable above all by the dark red abdominal dorsum being dotted black. Mexico. *divina*.

C. clarcana Dyar (56 e) is much smaller than *divina*, the forewing similarly marked, but all the markings broadly tinged white, particularly distinct the antemedian transverse bar, the spot at the cell-end, the median oblique stripe towards the middle of the proximal margin and the subterminal dentate stripe. Hindwing greyish-brown with a broad, curved, white median band. Abdominal dorsum red with rows of black dots. Mexico. *clarcana*.

78. Genus: **Opharus** Wkr.

Many of the most conspicuous species of this multiform genus have been published by HERRICH-SCHAEFFER, almost at the same time with (or already before) WALKER's diagnose (1855), as *Phegoptera*, but as no description of the genus was given and the first animal mentioned by this name (*porphyrea*, Außereurop. Schmett. p. 81, fig. 283) is a form of *Halisidota caryae*, the name was entirely cancelled; it might, however, be employed, if that group to which most of H.-SCHAEFFER's *Phegoptera* (*histrionica-piperita* group) belong would be considered as a special genus. But as one genus has already previously also been denominated „*Phaeoptera*“ (the first species enumerated being *Automolis erythronotus*, and the forms preponderantly belonging to *Amastus*), which is certainly due to inaccuracy and must lead to confusions, the name has been cancelled altogether. The genus *Opharus* itself, however, is not distinctly outlined and already according to its founder not uniform. In their exterior some strike us as *Amastus*, others as *Halisidota*, and some almost mimicry-like resemblances exist between *Opharus* and certain *Elysins*. The palpi are long and may be straightly porrect — occasionally even lowered —, but also bent up; the palpal terminal joint being stunted in most of the *Phegopterini*, may be even prolonged (*ruficollis*, *rhodosoma*). Also the antennae may be as long as those of *Amastus* and also be of normal length; they are mostly long, their teeth thickened at the ends. The venation is greatly modified already by the very different shape of the wings (*rhodosoma* very long, *aurogutta* quite short); the 1st subcostal vein in the forewing may branch off already right behind the middle of the upper cell-wall, but it may also accompany it beyond the cell etc. There is no anastomosis; the last bifurcation of the subcostal sometimes only takes place directly before the apical fringes, the upper radial comes from the upper, the two lower ones as well as the upper median from the lower cell-angle. The cell itself is of different length, in long-winged species with a very strong interior vein; the lower median vein leaves the median late. The genus extends from Mexico through the whole of Tropical America, but it reaches the United States only with 1 species extending little beyond the frontier; nothing seems to be known about the larvae.

O. flavicostata Dgn. (56 f), unknown to me, is based upon a ♂ from the Cauca Valley. Body dark brown, forewing lightbrown with a darker nebulous spot at the cell-end, and a sulphureous costal stripe. Hindwing whitish, at the apical marginal part brownish. *flavicostata*.

O. roseistriga Schs. (56 f). Forewings more stretched. Head light yellow, thorax honey-coloured, dorsum of abdomen brown, sides and apex golden yellow. Wings unicolorously dark sooty brown, forewing with a narrow, brownish-yellow costal-marginal stripe. Costa Rica, discovered by W. SCHAUS. *roseistriga*.

O. ferruginea Wkr. (56 e). More robust, thorax stouter, the border of the forewing steeper. Head above yellow, thorax and forewing nut-brown, the latter with a yellowish-brown costal-marginal and inner-marginal stripe as far as behind the middle of the wing. Hindwing diaphanous light brown, dorsum of abdomen orange, posteriorly with black transverse bands. Colombia. *ferruginea*.

O. brunneitincta Roths. (56 f). Unicolorously dark brown, forewing in the disc faintly lighter, hindwing diaphanous whitish except the brown margins and the apex, the veins dark brown. Peru. *brunneitincta*.

O. consimilis Hmps. (= *procroides* Drc. nec Wkr.) (56 e) is quite unicolorously brownish dusty-grey like *brunneitincta*, forewing little lighter, hindwing much lighter in the disc, but the abdomen has intense dark yellow lateral spots almost flowing together to bands towards the apex. Mexico and Central America and Colombia far as Peru. *consimilis*.

O. linus Drc. (56 f). Dirty greyish-brown, wings unmarked. Head above yellow, thorax marked pink with dark patagia, end of abdomen and sides of it yellowish-pink. Mexico. *linus*.

- albijuncta*. **O. albijuncta** Rothsch. (56 f). Dark brown, head and collar golden yellow, on the metathorax a bone-white spot. Captured by A. H. FASSL on Mt. Tolima in Colombia.
- bimaculata*. **O. bimaculata** Dew. (= *albipunctatus* Drc.) (56 g) has the shape of a Syntomid: forewings dark drab, hindwings hyaline except the dark margins. Head and thorax blackish, the patagia conspicuously creamy-white. Abdomen posteriorly sulphur-yellow with dark segmental indentations and a dark median line. Mexico, through Central America as far as South Brazil, local, but in some districts not rare. — Specimens from Venezuela are larger, the forewings of a less brown tinge, the hindwings not white but diaphanous grey, the posterior *major* dorsum of the abdomen more orange; this is the form **major** Rothsch.
- basalis*. **O. basalis** Wkr. (57 a). Greyish-brown, immediately recognizable by the head being yellow above and the yellow thorax, as well as a short, thick, yellowish-white streak at the base of the proximal margin of the forewing. Venezuela to South Brazil and Bolivia, dispersed.
- ruficollis*. **O. ruficollis** Drc. (56 g). Greyish-brown; head above and collar marked rosy-red, abdomen likewise purple-pink, also the inner-marginal area of the hindwing extensively tinged pink. Panama, the figured specimen from Costa Rica.
- draudti*. **O. draudti** sp. nov. (57 a). Size and shape of *laudia*, but wings dark brown head and collar fiery yellowish-red, and abdomen light brownish-yellow. The prothorax has 6 black dots, the abdomen a lateral row of dots, and the hindwing has a light yellow basal part. Forewing with an entirely obsolete, antemarginal transverse shade being defined on the lower radial. Beneath the body is dull orange, abdomen more brownish, wings coloured as above, all with a light yellow-ochreous base. Taken by ROBERTO MUELLER near Zaeualpan in Mexico.
- rhodosoma*. **O. rhodosoma** Btlr. (56 g) is much larger, the forewings finely transversely striated, the hindwings in the inner-marginal areas of a very bright pink tinge and haired. Head above and neck of a bright creamy yellow, abdomen pink, the posterior half with black transverse bands. Colombia and Venezuela to Peru and Brazil, apparently an alpine animal occurring only at great altitudes.
- almopia*. **O. almopia** Drc. (56 g). Wings much shorter and broader with a steeper border. Dark nutbrown, hindwing in the inner-marginal area a little lighter; abdomen posteriorly banded yellow. Colombia and Peru.
- procroides*. **O. procroides** Wkr. (56 g). Unicolorously sooty blackish-brown, hindwings in and below the cell of a whitish reflection and thinly sealed, abdomen posteriorly with large, lateral orange spots, those of the last segments touching each other above. Panama to South Brazil and Bolivia.
- belus*. **O. belus** Drc. (56 f). Head, collar and patagia, as well as the end of the abdomen yolk-coloured, the latter with a row of dorsal dots. Wings greyish-brown, hindwing lighter, forewing with 4 transverse bands bordered with dark, the distal ones being confluent towards the proximal margin. From the Chiriqui in Panama.
- laudia*. **O. laudia** Drc. (57 a). Body dull yolk-coloured, wings diaphanous whitish, tinged ochreous, with brown veins; forewing round the cell-end with a circular brightening encircled by a dark shade. Before me only from Venezuela, but apparently rather common near Merida. Reported also from Trinidad.
- trama*. **O. trama** Dgn. (= *euripides* Drc.) (57 b). Forewing dull yellowish-brown, the margins tinted ochreous-yellow, hindwing dirty yellowish-white diaphanous with a yellow margin. Also the body is yolk-coloured, shaded faintly darker. On the forewing the middle radial after its rise from the upper cell-angle slightly bends upward; here the veins are intensely marked dark. Colombia, Bolivia.
- polystrigata*. **O. polystrigata** Hmps. (57 b). Head and thorax dull honey-coloured, marked blackish; abdomen yellow with black transverse bands. Forewing whitish-grey, thinly sealed, all covered over with light yellow dots and striae, the veins and costal margin darker, border yellow. Hindwing dirty white, diaphanous, towards the margin darkened by grey. Bolivia and Peru.
- astur*. **O. astur** Cr. (= *albescens* Wkr., *maculicollis* Wkr., *pustulata* Pack.) (56 h). A very widely distributed lantern-butterfly mostly very common in dry districts. Head and thorax white, vividly dotted black, abdomen yellow with dorsal and lateral rows of dots. Forewing dull white, with brown, interspersed spots and undulate lines leaving round white spots between them. According to the district and season, the markings may be more intense or more feeble, but the species varies very much individually, mostly, however, only in the distinctness and intensity of the speckling and marking. — **arizonensis** Rothsch. (= *fumata* Barnes) (56 h), described from the Huachuco Mountains in Arizona, is distinguished by the light brownish marking on a uniformly whitish-grey ground-colour. This form seems to me to be one belonging to the very dry climate of the prairies, for it occurs again in Argentina in very hot and dry districts, from where I figure it. — **cubensis** Rothsch., on the contrary, has very dark markings in the ♂ and faded ones in the ♀, the ground-colour being brownish buff; from Cuba. — The species is extremely common in tropical districts and is to be found in almost every country from Arizona to North Argentina, being, however, mostly local.

O. nexa *H.-Schäff.* (= *flavopunctata* *Wkr.* nec *H.-Schäff.*) (56 h) has the size and shape of a strong *nexa*, *astur*, but the spots of the chains on the forewing are much more intensely encircled by black, and the ground-colour between is more intensely marked and shaded dark, the hindwing is grey with a distinct dark cell-end luna and a broad marginal band watered somewhat yellow and light; the dorsum of the abdomen is without the dark dorsal dots, but its proximal half covered with a black fur; from Brazil. — **albimacula** *Jones* (= *albimaculata* *albimacula*, *Rothsch.*) is smaller, the spots on the forewing encircled more with brown than black, the hindwing being light whitish-grey, darkened only at the border, only the 3 last abdominal segments being orange-yellow above. Likewise from Brazil; I do not find any more exact habitats stated.

O. punctularis *H.-Schäff.* stands between *flavopunctata* *H.-Schäff.* and *astur* which it resembles so *punctularis*, much that it was taken to be the ♀ of it. By the white colour being increased and very light it resembles a specimen of *flavopunctata* with a very light ground-colour. Brazil.

O. flavopunctata *H.-Schäff.* (56 h). Like *punctularis*, but the abdomen is more extensively marked *flavopunctata*, black, and the ground-colour of the forewing is a delicate, light violettish-grey. Brazil.

O. depicta *H.-Schäff.* (56 h). Larger, similarly marked to the preceding, but the spots of the forewing *depicta*, being encircled by black almost recall an *Ecpantheria*; thorax above marked in a bright purple and the abdominal dorsum is likewise purple-red except a blackish-brown shabrack. South Brazil.

O. hampsoni *Rothsch.* (= *decrepida* *Hmps.* nec *H.-Schäff.*) (57 a). Much smaller than *depicta*, *hampsoni*, thorax and forewing light chestnut-brown, with very few, thin, white catenary markings bordered with dark and not reaching the proximal margin. Abdomen all over haired blackish-brown, only the last third is orange with black dorsal and lateral dots, the apex being again black. From Venezuela and Ecuador to Bolivia and Peru. — **discisema** *Hmps.* (= *irregularis* *Rothsch.*) (57 a) scarcely differs from light specimens of *hampsoni*, *discisema*, as they are before me from the Rio Songo (beside darker ones), except the white markings being somewhat broader and thereby more coherent. Colombia, the type from Mt. Tolima. According to HAMPSON a distinct species.

O. granifera *Schs.* (56 h). Not much larger, but with much broader wings than the preceding; between *granifera*, the white macular markings the yellow ring-chains extend, like in *depicta* and its allies. Hindwing grey, towards the margin darker. Thorax with bright white and yellow markings; abdomen posteriorly orange. South Brazil.

O. schäfferi *Schs.* (= *nexoides* *Schs.*) (57 b). Larger than the two preceding; on the forewing the *schäfferi*, yellow catenary markings are reduced, the white markings, however, increased. Base of forewing dark brown with 2 thick orange dots. South Brazil, Venezuela.

O. histrionica *H.-Schäff.* (57 b). Still larger, the white markings of the forewing increased to a net *histrionica*, with wide meshes of white bands, the pupils of the macular chains, as well as the terminal third of the abdomen of a deep orange-red. Hindwings spotted whitish-grey, without any real hyaline patches. South Brazil, from the more distant surroundings of Rio, and in São Paulo.

O. chorima *Schs.* (57 b). Size and habitus of *histrionica*, but the white markings on the forewing *chorima*, of the latter are in *chorima* brownish-yellow, the ring-spots, particularly those in the distal third larger, the hindwings more uniformly dark grey. In the Brazilian state Paraná, discovered by W. SCHAUS near Castro.

O. superba *Dre.* (57 c). A very beautiful and large species. Head and thorax marked fiery reddish- *superba*, yellow, the forewing grey with reddish-yellow, black-encircled ring-spots and bands, the antemedian one bent round on the median, the postmedian one interrupted several times, the subterminal one broken up into isolated rings, the terminal one formed of cucullate spots; hindwing reddish-yellow with a blackish median luna and marginal band, abdomen fiery reddish-yellow, the middle of the dorsum dark with red hair. Santos in South Brazil, rare.

O. sestia *Dre.* (57 c) is much smaller, the ground of the forewing dark brown, intermixed with *sestia*, chains of guttiform spots; behind the base, from the apex and proximal angle large, bone-yellow demi-bands. Hindwing with a whitish proximal and greyish-brown marginal half, at the cell-end a greyish-brown nebulous spot. Head and thorax brown, marked whitish and orange, abdomen orange, banded dark. Peru.

O. picturata *Burm.* from Uruguay is known to me from BURMEISTER's description. Somewhat larger *picturata*, than the preceding, head and body orange, head and thorax marked black, abdomen orange, the 2nd ring almost quite black, in the terminal part black dorsal spots. Forewing with 6 black oblique bands, on which there are rows of dull spots, the 6th band narrow. Hindwing with traces of 3 dark bands, that at the margin being the most distinct. Conchas.

O. decrepidoides *Rothsch.* (57 c) is somewhat allied to *O. hampsoni*, but the light markings are not *decrepidoides*, white, but brownish bone-coloured, between the median and distal costal macular bands an intensely dark brown cloud. Hindwing faintly diaphanous greyish-yellow, with a dark cell-end spot and distal band leaving

free, however, the margin in the apical area. It somewhat resembles in the habitus *Elysius melanoplaga* (54c) occurring also at the same place. Colombia to Peru.

decrepida. **O. decrepida** H.-Schäff. (57 c) also exhibits a resemblance to *hampsoni*, but the transverse bands which are there only indicated by dispersed, whitish, small crescents and spots, are here passing through from the costa to the median, those in the basal and terminal thirds reaching even the proximal margin; they are of a dark yellow tinge, bordered with blackish. Hindwing similar as in *decrepidoides*, but without the distinct median luna, and the apex itself is still darker than the marginal band, not lighter. Guiana, Venezuela and Peru.

flavostrigata. **O. flavostrigata** H.-Schäff. (57 c). Wings coloured not dissimilarly to *nexa* (56 h), but the forewing above without the purely white embeddings, only with a light violettish-grey subterminal band being continued also on the hindwing. Easily recognizable by the black, somewhat lustrous bluish-grey abdominal dorsum, the sides of which there are rows of deep orange-red spots. „Brazil“, the exact habitat not being mentioned.

flavimaculata. **O. flavimaculata** Hmps. (57 d). Dark greyish-brown, with bone-white spots on the tegulae, a broad macular band behind the base of the forewing, an oval spot before the upper cell-angle and 3 spots at the costa before the marginal fourth; some more minute, yellowish-white spots are dispersed across the forewing with 2 small purple spots in the cell-angles. Hindwing with 3 spots in the cell being above tinged pink, beneath yellow. The subbasal spots of the forewing, however, are on the contrary yellow above and beneath partly pink. Abdomen banded purple. South Brazil and Peru, figured according to a Bolivian specimen from the Rio Songo.

piperita. **O. piperita** H.-Schäff. (= *aureopuna* Rothsch.) (57 d). In this species there are only yet small bone-white spots scattered over the forewing and thorax, being in the ♂ only of the size of a pin's head, in the ♀ of a millet-grain. But sometimes the ground of the wing is densely covered with small light dots. Hindwing light yellowish-grey, faintly diaphanous, with a large costal-marginal spot at the cell-end and a broad marginal band. Abdomen posteriorly banded purple. From Trinidad and Costa Rica to Brazil, Peru and Bolivia; the figured ♀ from the Rio Songo.

ovuliger. **O. ovuliger** sp. nov. (57 d) differs from the preceding genus by the more abundant and more dense bestrewing with lemon-coloured, small oval spots. They are united to thronged rows and appear more distinctly also on the thorax, and the ♂♂ are besides much larger than in *piperita*, even in the ♀. Found by A. H. FASSL near Pacho in Colombia. Type in the Coll. FASSL.

intermedia. **O. intermedia** Rothsch. (57 d). One specimen (♀) in the Tring Museum, the habitat being unknown, in contrast with *ovuliger*, shows the yellow above compared to *piperita* reduced to single spots, of which there are only a few larger ones at the costa. The hindwing is quite dark brown except some discal spots. We have copied HAMPSON's figure of the species in his „Catalogue“.

aurogutta. **O. aurogutta** Schs. (57 d). Spots of the forewing very numerous, more circular than oval. Hindwing dirty yellowish-white, in the ♀ shaded with grey. Bogotá (Colombia).

fasciatus. **O. fasciatus** Rothsch. (57 e). Habitus of a *Calidota*, also the head and prothorax dotted black like in them, too. Forewing light brown, with transverse rows of white oval spots. hindwing dirty white, at the border brownish. Venezuela.

ochracea. **O. ochracea** Joicey (57 e) is somewhat smaller and distinguished from *fasciatus* only by the white spots in the proximal part of the forewing being extended into short bands which are much smaller in the distal part. Peru.

elota. **O. elota** Mschlr. (57 e). Unicolorously ochreous-yellow, wings lighter in the disc, body shaded darker. Jamaica; described as *Halisidota*.

thalassina. **O. thalassina** H.-Schäff. (57 e). One of the largest species; body yolk-coloured, marked whitish. Wings diaphanous Nile-green with dark veins, the marginal parts tinged yellowish. From Central America through Colombia, Venezuela and Brazil as far as Rio de Janeiro; in many places rare, in some, however, (e. g. Merida in Venezuela) common on lanterns. Its exterior already reminds us of the *Amastus*.

albescens. **O. albescens** Rothsch. (57 e) which we append here, according to HAMPSON belongs to the genus *Ochrodota* and would, therefore, have to be inserted on p. 334. It is quite pale ochreous-yellow, the forewing covered with small dark dots and small brown spots in such a way that the animal looks like a *Halisidota* and might be compared to *H. cirphis* (57 k) or *jonesi* (58 e); from Venezuela and Guiana.

79. Genus: **Graphelysia** Hmps.

A very peculiarly marked butterfly, described as *Elysius*, but probably not even distantly related to this genus, was discovered in a male specimen in Peru (la Union) and figured by LORD ROTHCHILD. It is

perhaps the most closely allied to the *Euchaetias*-group and the larva may prove it to be alien to the *Phegopterini*. Characteristic marks are: a pointed frontal cone, a very feeble proboscis, and short, projecting palpi. In the forewing the 1st subcostal vein rises shortly before the upper cell-angle, the 4 others have a long, common footstalk. The upper discocellular is of medium length, the middle one bent in angularly, the lower one short. All the veins are present in the hindwing.

G. strigillata *Rothsch.* (49 h). Blackish-brown, collar and metathorax, as well as chest orange, forewing *strigillata*. with numerous, silvery white transverse striae. Carabaya (Peru).

80. Genus: **Hyalarectia** *Hmps.*

This genus contains 2 pale yellow butterflies of an *Halisidota*-like habitus. On both wings the upper median vein branches off far before the lower cell-angle, the two lower radials come from the lower cell-angle itself, the upper one with the subcostal resp. with the pedicle of its 3 last branches from the upper cell-angle. On the forewing the two first subcostal veins rise from the upper cell-wall.

H. tepica *Dyar* (48 g) is before me only from Mexico. Wings quite unicolorously pale yellow, head *tepica*. orange, body tinted orange. Rare.

H. sericea *Schs.* is somewhat more robust, but of the same expanse of wings, likewise quite pale *sericea*. yellow, diaphanous, somewhat silky lustrous, with darker veins; at the base of the forewing a small orange spot; the dark dots on the patagia a little more distinct. Castro, in the Brazilian State Paraná.

81. Genus: **Pseudopharus** *Hmps.*

Almost exactly like the preceding genus, on the forewing the 2nd subcostal vein also rises from the upper cell-wall, and all the discocellulars are strongly angled like in *Hyalarectia*, but on the hindwing vein 5 is absent and the upper median vein rises with the lower radial from the lower cell-angle. 4 species are known.

Ps. domingona *Drc.* (48 g). By the white spots on the patagia it somewhat recalls *Opharus bimaculata domingona*. (56 g), of which it has also the sooty blackish-brown forewings, diaphanous white hindwings, and posteriorly orange abdomen; but the abdominal bands are not separated into lateral spots by a dorsal line, and beside the two white patagial spots there is a third on the metathorax. Peru.

Ps. hades *Dgn.* Size and colouring similar to the preceding, but the whole marginal half of the hindwing *hades*. sooty dark. Abdomen with only very narrow orange bands, otherwise blackish-brown. From Mt. Tolima in Colombia.

Ps. cornelia *Drc.* (48 g). Likewise greatly approximating the preceding, hindwing only in and round *cornelia*. the cell diaphanous whitish, abdomen with orange-yellow dorsal bands and lateral spots. Peru.

Ps. amata *Drc.* Somewhat larger than the preceding (50 mm), head and thorax sooty black, and *amata*. the abdomen above with orange transverse bands. Forewing deep olive-brown, suffused with a dark brown, particularly towards the margin. Hindwing black, in and round the cell somewhat more diaphanous, but not white as in the preceding. Venezuela.

82. Genus: **Metacrisia** *Hmps.*

This genus in its habitus already approaches the *Halisidota*, but the whole body, particularly tibiae and femora of all the legs, are very strongly haired. Proboscis strong, palpi projecting directly forward, the terminal joint not stunted. Head and thorax densely and long haired. The two first subcostal veins rise separately before the upper cell-angle; out of the latter rise, from the same place, the footstalk of the 3rd to 5th subcostal veins and the uppermost radial; the upper median branches off somewhat before the lower cell-angle; the same is the case on the hindwing, where all the veins are present. They are alpine animals, adapted to a more rough climate, nothing is known about the larvae.

M. schausi *Dgn.* (57 f). Head and thorax chestnut-brown, abdomen dark, yolk-coloured. Forewing *schausi*. in the median area chestnut-brown with yellow spots in and below the cell, marginal and basal areas pale yellow with royal yellow embedments, the border between the basal and median areas is formed by a distally convex bow. Hindwings of a paler yellow. Quindiu Pass (Colombia).

M. courregesi *Dgn.*, known only from Loja in Ecuador, is similar but more unicolorous, the median *courregesi*. area of the forewing not so prominently dark; the border between the light basal area and the median area forms an acute angle with a distally directed vertex, situate in the middle of the cell.

pua. **M. pua** Dyar (57 e) is quite unicolorously pale ochreous-yellow, the forewing traversed by lighter veins. Larger than the preceding. From Mexico (Guerrero).

83. Genus: **Hypidota** Schs.

Distinguished from all its allies by the stunted proboscis, owing to which also the palpi are much shorter; the middle joint scarcely longer than the short basal joint, the terminal joint rudimentary. In the forewing the 1st subcostal vein comes about from the middle of the upper cell-wall, the 2nd branches off rather far before its end, 3 to 5 have a long footstalk. Transverse vein very slightly curved in. Only 1 unicolorously yellowish species is known, from the northern part of South Brazil, and of this only the ♂.

neurias. **H. neurias** Schs. (57 f). Unicolorously whitish ochreous-yellow, with reddish-yellow antennae, orange-yellow abdomen, and brownish veins on the wings. Castro (Paraná).

80. Genus: **Microdota** Dgn.

Proboscis feeble, but still present. Palpi long, projecting, particularly the middle joint well developed, twice as long as in the preceding genus. Cell very broad and long, the 1st subcostal vein branching off behind the middle of the upper cell-wall, the 2nd rising directly before the upper cell-angle. Only one very small species (expanse: 20 mm).

lenistriata. **M. lenistriata** Dgn. (= *pellucida* Rothsch.) (57 f). Wings almost quite hyaline, forewing at the border, and hindwings quite faintly tinged yellowish. The transverse vein of the forewing and the posterior part of the lower cell-wall more distinctly marked. Venezuela, Paraguay.

85. Genus: **Nannodota** Hmps.

Scarcely larger than the preceding genus, but the proboscis fully developed. Different besides from *Hypidota* by the palpi not being shortened, but in contrast with *Microdota*, they are not straightly porrect, but bent up before the face. The anterior legs show long hair-brushes on the inside of the tibiae and femora. On the forewing the 2nd subcostal vein rises but slightly before the upper cell-angle, this being a mark of distinction from *Halisidota* which genus the *Nannodota* already approximate very much.

minuta. **N. minuta** Rothsch. (57 f). Like a very small *Halisidota*, as which it was also described. Body and forewings of a very bright yellow, the latter bestrewed with numerous, small, brown dots and hooks, a somewhat distinct, small, dark spot above the anal angle. Hindwings pale yellow. Peru; apparently not common.

86. Genus: **Thalesa** Schs.

Almost entirely like *Halisidota*, approaching some of them (for instance *annulosa*, *catenulata* a. o.) so very much that the distinction is only possible by means of a magnifying glass, the difference consisting in the absence of vein 5 on the hindwing, whereas in *Halisidota* all the veins are present. The larva exhibiting also the white, long, thin pencils on the anterior and posterior parts has besides paired, above smoothly elipped brushes on the 3rd to 10th segments. All the forms are very closely allied to each other.

citrina. **Th. citrina** Sepp (57 f). Forewing bright yellow with numerous, finely marked annular rows running parallel to the border. Behind the middle, likewise parallel to the border, a brown nebulous line. The apical part of the costa and the whole proximal margin, except the base of it, are brown. Mexico to the Amazon. —

seruba. **seruba** H.-Schäff. (= *albipuncta* Rothsch.) is a larger form from Ecuador and Peru with a very strong median oblique stripe and thick inner-marginal stripe. — **parva** Rothsch. (57 f), from East Colombia to Guiana and the Amazon, is a small form of pale markings, which I figure from Villavicencio. — Larva of a delicate rosy-red with a similar head with white markings, and yellow lateral markings tinted in a flesh-colour. Across the dorsum and on both sides longitudinal rows of brownish brushes with reddish-white crowns, and on the anterior and posterior parts there are long, white hair-pencils projecting beyond the larva. It lives on *Inga vera* and changes into a mahagoni-brown pupa in an oviform web intermixed with hair, yielding the imago after about 11 days.

amaxiaeformis. **Th. amaxiaeformis** Rothsch. (57 f) entirely resembles a *citrina* in its shape and size, but the forewing is of a paler yellow, the median stripe is absent and the dark annular rows are more scanty, in some places scarcely indicated. Ecuador.

Th. debilis Schs., from Mexico and Central America, is unknown to me. Expanse of wings: 31 mm. *debilis*. Body and forewings light brownish-yellow, the hindwings with numerous, undulate transverse lines, an antemedian line is bordered by greyish shades, and a similar one extends from the subcostal through the middle to the proximal margin. On the tegulae and the transverse vein 1 black dot each; hindwings yellowish-white.

87. Genus: **Halisidota** Hbn.

A collective genus of very numerous, often rather similar and transitory species, which has several times been divided into subordinate groups (*Euhalisidota*, *Schausia*, *Euschausia* etc.). The prevailing colour is a straw-colour, the chief marking consisting of annular rows parallel to the border, mostly only noughts or ovals of the ground-colour, sometimes, however, also filled with white. Some species exhibit also cell-end shades in the forewing, and the ♂♂ of certain species have scent-pads in various places of the wing. Proboscis always strong, palpi bent up and of medium length, with long middle and stunted terminal joints, body of the ♂ pointed, of the ♀ cylindrical, but not essentially swollen. The venation is not quite homogeneous in the genus. The 2nd subcostal vein of the forewing may branch off before and behind the cell-end. Also the antennae may have long or also short teeth in the ♂. More typical is the larva, i. e. as far as its early stages are known hitherto. In its anterior part there are some thin long hair-pencils mostly pointing forward, whilst in the posterior part there are 2 to 4 of them pointing backward, the dorsum itself being rather uniformly haired. Pupa mostly in a thin, but very equally worked cocoon.

More than 250 names have been given to the species of the genus, but the delimitation of the species from each other and the homogeneousness of the forms is still very imperfectly known. Many species are extraordinarily wide-spread and are found without any conspicuous deviations from South Canada to Buenos Ayres, and there is hardly any place in Tropical America where there is not at least one *Halisidota*-species to be found. Some species are, moreover, very common, particularly on the light. All seek their food, have an active proboscis and seem to visit the saps of fruit as well as blossoms. In day-time they are not very much inclined to fly, but by means of their agile legs they are able to move quickly, in spite of the structure of the ♀♀ being sometimes clumsy. The butterflies, whilst creeping around with their long legs, their shuffling bodies, their long, groping antennae and the long wings shoved together posteriorly, entirely resemble the *Rhodogastria* of the east.

When grasping the animal, and particularly when pressing the thorax with one's fingers, the body proves to be very elastic and succulent. The sap exuding from the glands at the neck in the shape of drops, has an oily smell and consistency. The *Halisidota* are very tenacious of life.

H. catenulata Hbn. (57 g). The smallest species of the genus, rather similar to the species of the *catenulata*. preceding genus (*Thalesa*); forewing yellow with a dark proximal margin, transverse rows of brownish rings and brown transverse bands, of which in typical specimens mostly an antemedian and a postmedian stripe are distinct. — In the form *sesia* Sepp there is in addition yet a proximal (basal), a median and a shortened *sesia*. subapical, dark brown stripe, whereas contrarily to *walkeri* Rothsch. only the postmedian stripe is distinctly *walkeri*. prominent. — Larva white and white-haired with a yellowish-brown head, green anterior end, and black dorsal spot on the 2nd segment. Across the dorsum runs a dark longitudinal stripe. The pencils at the anterior end are pointing obliquely forward, those at the posterior end backward. It lives on *Inga vera*, and in a white web similar to a bird's egg it changes into a green pupa yielding the imago after a fortnight. From Mexico to Argentina and Bolivia, also in Cuba, nearly everywhere common.

H. polyodonta Hmps. (57 g). Slightly larger, likewise yellow, but somewhat darker, the forewing *polyodonta*. without the dark transverse stripes of the preceding species, with rows of small dark dots; below the cell-end a nebulous spot. From Trinidad through Venezuela, the Amazon District and Colombia as far as Ecuador and Peru.

H. subannula Hmps. (57 g). Somewhat larger than the preceding, pale yellow, the forewings with *subannula*. faint traces of the undulate lines, or rows of small dots, but with distinct dark transverse lines, 3 of which are in the basal third, behind the middle, and one in the marginal third. At the end of the cell on the forewing above a dark dot, and below the middle of the costa on the hindwing beneath a brown ring. Costa Rica, Peru.

H. annulosa Wkr. (= *nimbifacta* Dyar) (57 g). Like the preceding rather small, pale yellow, the *annulosa*. brownish undulate lines complete, but rather indistinct; distinct only a somewhat curved, oblique transverse streak through the middle of the forewing. No dark marginal dots; the brownish inner-marginal streak of the forewing quite faint. — In the form *niveigutta* Wkr. there is behind the lower cell-angle of the forewing a small, *niveigutta*. silvery white guttiform spot. Mexico.

H. texta H.-Schüff. (= *thyophora* Schs.) (57 g) is similar, larger; instead of one median there are *texta*. here 2 brown transverse stripes in the forewing, an antemedian and a postmedian one. Both come from brown, triangular, small costal spots. The inner-marginal stripe is distinct and of a deep brown in Mexican speci-

mens. — In specimens which I took at Montevideo, corresponding to such described by ROTHSCILD from Peru, the inner-marginal stripe is absent, the forewings and above all the abdominal dorsum are quite pale yellow; this is *pallida* Roths. — In *tucumana* Roths. from North West Argentina, on the reverse, the brown inner-marginal streak is short, but strong and dark, and the distal oblique streak in the forewing is broad. Brazil, Argentina, Uruguay, and Peru.

distincta. **H. distincta** Roths. (57 g). Considerably larger, the undulate transverse lines of the forewings numerous and mostly distinct, a median and mostly also a subbasal, nebulous transverse stripe of the forewing distinct, into the middle of the thick, deep brown inner-marginal stripe a small, bone-coloured longitudinal spot is embedded. From the preceding it differs by deep-brown marginal dots of the forewing. From Venezuela and Colombia, particularly common on Mount Tolima. — *brunnes-cens*. **H. brunnes-cens** Roths. from Peru differs by a more reddish tinge and more expanded brown markings.

major. **H. major** Roths. (57 h). Considerably smaller than the preceding, owes its name only to the resemblance to *walkeri* to which it was at first added as a larger form of it. Like in *walkeri*, there is here no distinct inner-marginal streak of the forewing; the red-brown undulate lines are distinct and very uniform, and of the transverse shades mostly only that directly behind the middle is distinct. Widely distributed, from Costa Rica through Colombia, Venezuela to Brazil and Peru.

alsus. **H. alsus** Cr. (= *pectina* Schaus) (57 h) is immediately recognizable by the very long-pinnated antennae, otherwise in the marking very much like the preceding, but the transverse shades in the forewing are broader, the proximal one being angled on the median, touching at the proximal margin a dentate line which is not angled on the median. The distal transverse shade brown, on both margins worn out, intermixed with small yellow spots and a small, white vitreous spot at the lower cell-angle. Hindwings quite pale yellowish-white. Mexico and Central America through Colombia and Venezuela to Ecuador and Peru.

sobrina. **H. sobrina** Mschr. (= *modesta* Ky., *laropia* Dre., *laripa* Dgn.) (57 h). Very much like the preceding, but the ♂ with narrower wings, the forewings without any real transverse bands, only before the middle of the cell there is a large, brown costal spot, and another interrupted or sand-glass shaped spot at the cell-end. The species is recognizable by a longish, reddish-yellow scent-pad on the forewing beneath covering the whole cell as far as the lower cell-angle. From Costa Rica through the northern parts of South America as far as Bolivia and Peru.

eudolobota. **H. eudolobota** Hmps. Above quite similar to the preceding species, in its size and yellow colouring like *sobrina*, but the dark spots at the costa and cell-end less prominent and the single waves of the undulate lines not so coherent. Immediately recognizable by 2 hairlocks at the sides of the abdominal base in the ♂, as well as by a dense scent-fur occupying the whole submedian space of the hindwing beneath. From the Upper Amazon.

atrimaculata. **H. atrimaculata** Hmps. (57 i). Similar to the preceding, but along the costa and proximal margin of the pale yellow forewing there are single, scattered, thick, blackish-brown spots, like in the cell, and at the margin there are thick marginal dots. From Venezuela to South Brazil and Peru.

dognini. **H. dognini** Roths. (57 k) is unicolorously yellow, the hindwings lighter, forewings and patagia with small black dots. Besides there is in the cell of the forewing an angular, at the cell-end an interrupted spot and from the latter to the proximal margin behind the middle a row of dark striae. Peru.

endrolepia. **H. endrolepia** Dgn. (= *androlepia* Hmps., *sobrinoides* Roths.) (57 h) approximates *atrimaculata*, but the ♂ is without the thick dark spots, pale yellow and very finely marked; forewings of the ♀ coarsely strewn dark. From Guiana, Trinidad, and Venezuela to Bolivia and Peru.

maroniensis. **H. maroniensis** Schs. (= *buchwaldi* Roths.) (57 h). Smaller than *endrolepia*, the forewings without the coarse dark strewing of the ♀ of *endrolepia*, the transverse lines, however, particularly in the median area, are distinct and coherent; at the margin faint marginal dots. Guiana and Amazon.

cyclozonata. **H. cyclozonata** Hmps. (57 i) differs from the preceding by the antemedian dark band running thick and twice interrupted through the forewing, and by the distal part of the forewing showing a violetish-grey, cloudy darkening, in which the yellow ground-colour is only yet left in single yellow, partly red-pupilled, small guttiform spots. Guiana through the Amazon District to Ecuador and Peru.

grandis. **H. grandis** Roths. (57 i) differs from *cyclozonata* chiefly only by the small red-pupilled spots in the distal part of the forewing being arranged to transverse rows. Costa Rica to Peru. — This form, according to HAMPSON, might be an aberrative form of the preceding, like *sammionis* (57 h) which was described as *Baritius* and, therefore, also dealt with at large by us on p. 332.

lactogrisea. **H. lactogrisea** Roths. (57 i). Considerably larger than the preceding, the forewing light yellow, strewn with golden yellow, the small golden yellow spots with dark borders and arranged to an antemedian band as well as a submarginal row of spots. In the disc 2 dark cloudy spots, at the cell-end and in the submedian space. Venezuela.

H. stipulatoides *Rothsch.* (57 i). Forewing pale yellow, in the proximal part, particularly at the costal and proximal margins, of a bright golden yellow tinge. The small dark spots are small and faded in the basal and median areas, larger antemarginal nebulous spots are at the costa, behind the lower cell-angle and above the proximal margin; right through the marginal area extends a curved row of proximally pointed sagittiform spots. From Guiana through Venezuela and the Amazon District to Peru. *stipulatoides.*

H. malodonta *Dyar* (57 i). Size and shape of *lactogrisea*, but the dark markings of the forewing are quite scanty and faded except an antemarginal row of brown ellipses. Body and principal veins of the forewings of an orange-red tinge. From Huadquina in Peru. *malodonta.*

H. nebulosa *Rothsch.* (57 i). Smaller, of a paler yellow, the dark undulate lines in the forewing entangled, on the median a brown streak, continued to the apex; an antemarginal row of small dark rings. Amazon, Ecuador and Peru. *nebulosa.*

H. longipennis *Dgn.* (57 i). The dark markings on the pale yellow forewing are arranged in longitudinal rows extending through the cell and along the submedian. An antemarginal, interrupted chain of faded rings, at the border a row of dots. From Yungas de la Paz in Bolivia. *longipennis.*

H. pulverea *Schs.* (57 k). This apparently rare species approximates *stipulatoides* (57 i), of which it has the orange body, costal margin and border of the forewing; the latter otherwise exhibits only dull grey punctiform spots divided in irregular groups. South Brazil (Rio, Castro). *pulverea.*

H. perdita *Schs.* is allied to *pulverea* (57 k). Collar and thorax ochreous-brown, abdominal dorsum dull brown. Forewings dull yellowish, darkly strewn, indistinct lines; a line from the costa near the base, below the cell well bent out and rounded off; a less distinct line as far as vein 2 and connected with the first above the submedian by a denser strewing. A double, dentate postmedian chain of small crescents; an antemarginal, deeply angled line; the angle marked at the proximal side by black dots; black marginal vein-dots; a thick black dot at the cell-end, from which a faint dark line extends to the apex. On the hindwing the space below the cell and from vein 2 to the proximal margin smoky-grey. 42 mm. Guatemala (Cayuga). *perdita.*

H. liparoides *Rothsch.* (57 k). Forewing similar as in the preceding except in the median area some larger, narrowing dark spots, but easily recognizable by a chain of 4 large brown spots before the anal part of the border of the hindwing. Also the abdominal end shows black dorsal dots on an orange ground. Guiana, Amazon, Peru. *liparoides.*

H. contempta *Rothsch.* (57 k). In this small, pale yellow species with a slim body the only markings consist of some small, obsolete dark dots before the border of the forewing and in the disc, and a nebulous, diffuse spot on the submedian. From Fonte Boa (Amazon). *contempta.*

H. nimbiscripta *Dyar* (= *pseudofalacra* *Rothsch.*) (57 k). Unicolorously pale bone-coloured, the forewings intermixed only with single, small black scales grouped to a pale basal ray on the median. some few ellipses in the cell and a black middle dot at the lower cell-angle. Mexico and Nicaragua. *nimbiscripta.*

H. cirphis *Schs.* (57 k) approaches the preceding, but beside the basal ray and cell-end dot the forewings are also strewn with other dark brown dots; besides the abdominal dorsum is blackish-brown, except the yellow end. Costa Rica. *cirphis.*

H. democrata *Schs.* ♀. Body pale ochreous, the patagia anteriorly with a black dot. Forewings whitish-yellow, a slightly darker strewing forms rather indistinct markings; an antemedian undulate line in the cell bent out about in the middle of it, then bent into the submedian; above and below the cell-end some shading; at the cell-end a small dark spot; a postmedian interrupted line and a marginal undulate line. Guatemala (Cayuga). 40 mm. — The description neither mentions, where the species is to be inserted, nor does it compare it with a well-known species. *democrata.*

H. leucanina *Fldr.* (= *infucata* *Berg*, *phellia* *Drc.*) (57 k). Forewings dull ochreous-yellow, sometimes tinted grey or brownish, little marked, intermixed with single, small blackish scales, only one intense, sometimes light-centred dot at the lower cell-angle being blackish-brown. At the border a series of very fine ellipses, the proximal part of which is filled up by a brown dot. Abdominal dorsum blackish-brown, the apex pale yellow. Colombia through Brazil to Ecuador and Argentina. *leucanina.*

H. bactris *Sepp* (= *luideoides* *Rothsch.*). This rather widely distributed species resembles a large *bactris*. *Leucania* in the shape of the forewings by the curved border and the somewhat projecting apex. It is easily recognizable by the long antennae provided with very long teeth, the dark grey abdominal dorsum and the hindwing being sometimes quite blackish-grey in the anal half. The marking of the wings is very inconstant.

- jalacra*. In typical *bactris* the forewings are by far more traversed by transverse nebulous stripes than in the form *falacra* Dgn. (57 k) figured by us, where they are almost unicolorously yellowish-brown, finely dusted with blackish. Whilst *bactris* is described from *Surinam*, *jalacra* originates from Colombia and is distributed as far as Bolivia and Peru. — ***apicepunctata* Schs.** (58 a) looks very differently, but it still seems to me to belong to this species. Here the forewing has, beside the dot at the lower cell-angle, another one in and before the apex, and the hindwing an antemarginal band of greyish-brown nebulous spots, tapering off from the anal angle towards the apex and withdrawing from the border, not reaching, however, the apex. — The larva of *bactris* is black and black-haired, with yellowish-red feet, the pencil at the anterior and posterior ends golden yellow directed in front resp. behind, as in most of the *Halisidota*. It lives on *Bactris acanthocarpus* and changes from a grey cocoon into a brown pupa *).
- coniota*. ***H. coniota* Hmps.** (58 a) is a large species with an entirely grey body tinged orange only at the head and prothorax. Forewing dull bone-yellow irrorated with fine brown atoms and small dark punctiform spots along the costal margin and border, as well as at the lower cell-angle. Hindwings grey, in some parts tinted yellowish-red. Guiana to South Brazil, Bolivia and Ecuador.
- longa*. ***H. longa* Grt.** (58 a) replaces *coniota* in the north and seems mostly or exclusively to come from Florida (Jacksonville, February; Enterprise). Here the marking is very dull, more distinct are only a streak through the small dark spot at the lower cell-angle and some small preapical spots. Hindwings diaphanous yellowish-white.
- cuneipuncta*. ***H. cuneipuncta* Rothsch.** (58 a). Body and wings unicolorously pale ochreous-yellow, the forewing with quite faintly darker markings consisting of a feeble shade at the forkings of the median, some striae at the costa, small antemarginal sagittiform spots and small marginal rings. Mexico.
- angulata*. ***H. angulata* Rothsch.** (58 a). Whilst the ♀ greatly resembles *cuneipuncta*, the ♂ shows bright colours, particularly a red tinge at the thorax and a blackish-brown tinge at the end of the abdomen. Forewing with a dark brown costal stripe, a brown longitudinal ray in the submedian space, a blackish bow behind the cell-end and a curved brown antemarginal line. Peru.
- epinephete*. ***H. epinephete* Hmps.** (= *nebulosa* Rothsch.) (58 a) is dull ochreous-yellow, the forewing with very numerous rows of yellowish-red rings and undulate lines. A small, postmedian, somewhat curved, little prominent nebulous band. Hindwings diaphanous bone-coloured. Rio, through the Amazon District as far as Ecuador and Peru.
- pseudomanda*. ***H. pseudomanda* Rothsch.** (58 b) is similar, but the forewing scarcely shows traces of the dark transverse band, but a brighter brown costal margin and more densely arranged undulate lines. Guiana, Peru.
- dallipa*. ***H. dallipa* Jones** (58 b). Almost quite unicolorously bone-white, only the prothorax and neck finely tinged purple. Forewing strewn with scanty, small, black scales; an antemarginal row of extremely delicate, tiny dots. From the Brazilian state of Paraná.
- flavorufa*. ***H. flavorufa* Rothsch.** (58 b). Body yellow, brightly tinged pink. Hindwings pale yellow, irrorated with many red-brown atoms, which are concentrated behind the lower cell-angle round a white guttiform spot and form likewise behind the cell a brown, white-pupilled diffuse spot and a similar one above the proximal margin. Guiana and Ecuador.
- perdentata*. ***H. perdentata* Schs.** (58 b). Greyish ochreous-yellow, the forewing in its apical part very much darkened its marking consists of two rows of brown hook-shaped spots and of an antemarginal row of small dark rings. Mexico; the species is apparently rare or of a small range.
- albipennis*. ***H. albipennis* Hmps.** (58 b). This conspicuous species is easily discernible by the bone-white wings and the orange abdominal dorsum. Forewing with very delicate, small dots being more distinct only at the costal margin, and with parts of a postmedian undulate line. Bahama Islands.
- terranea*. ***H. terranea* Rothsch.** (58 b) cannot be confounded with any other species. Beside the brown marking of the forewing, the large spot in the cell, the smaller one at the cell-end, and the hook-shaped spot in the submedian space, the species is characterized by the hindwings being broadly margined with brown and by the abdomen being dark brown above. Thorax marked brown. Amazon.
- stipulata*. ***H. stipulata* Rothsch.** (58 b). In this larger species the abdomen is black only in its basal half, the posterior half and the thorax being yellow. Forewing yellow intermixed with white cuneiform spots and hooks, the most conspicuous one of which is situate behind the cell in a violettish-brown cloud. Hindwing with a grey inner-marginal area and small dark cuneiform spots at the apex. Guiana, Peru and Bolivia.

*) A remarkable fact is that the description of the larva almost exactly resembles the figure of the larva of *Automolis rutilus*, so that a mistake — probably of the larva of *A. rutilus*. — is not out of the question; the latter is figured on a twig of *Psidium*.

H. grotei Schs. (58 c). This peculiar insular form is unmistakable. Through the remarkably broad, *grotei*, pale bone-coloured forewing runs an indistinctly defined, somewhat fuzzy postmedian band, and 2 similar demi-bands extend from the costa, where they bifurcate, to the lower cell-wall. Hindwings with small, dark, ante-marginal diffuse spots. Cuba.

H. subterranea Rothsch. (58 c) is allied to *bactris*, and like *leucanina* (57 k) being allied to *bactris*, *subterranea*, it has an antemarginal row of small ellipses. The median area is brightly shaded with brown and intermixed with numerous small, whitish and dark brown spots; the whole hindwing, except the cell and the part behind it, is brown like the dorsum of the abdomen. Peru.

H. notodontina Rothsch. (58 d) is larger, the forewing more intensely shaded with brown, particularly *notodontina*, the whole costal-marginal area dull greyish-brown; the hindwing is in the costal-marginal area white, the proximal half yellow, the marginal part brown, enclosing some yellow marginal spots. Peru.

H. racema Schs. (58 c). Yellow, forehead and mesothorax brown. Forewing bright yellow with a *racema*, brown longitudinal stripe and many small striae at the costal margin, another brown longitudinal stripe extends from the cell-end towards the apex as a continuation of the median, another longitudinal diffuse spot in the submedian space. In the marginal third many brown, hook-shaped spots forming 3 transverse rows. Guiana.

H. subfasciata Rothsch. (58 d). Forewings quite pale yellow, traversed by 5 irregular, yellowish-grey *subfasciata*, transverse bands which are more distinct and broader in the costal part, but narrower and duller in the proximal part; their course is rather irregular. Hindwings white. Paraguay.

H. huaco Schs. (58 c). Body and wings dull greyish-brown, forewing with a broad, curved postmedian *huaco*, nebulous stripe and dark subterminal dots, hindwing with a lighter costal part and white antemarginal bosses. South Brazil (Rio, Castro).

H. moeschleri Rothsch. (58 c). Forewing traversed by irregular, dentate dark transverse bands, *moeschleri*, between which there are undulate or dentate lines, similar as in *subfasciata*, but the ground-colour is a bright red-brown. Jamaica.

H. squalida H.-Schöff. (58 c). Also here the yellowish red-brown forewing is crossed by transverse *squalida*, catenary stripes of crescents bordered dark: near the base, in and behind the middle as well as before the margin. South Brazil and Bolivia.

H. lua Dyar (58 c). Size and shape similar to the preceding, but only the postmedian and antemarginal *lua*, catenary stripes are complete; the one in the middle is only indicated by some rings. Hindwing with a dark discal luna and a subterminal dark distal band. Beneath all the wings show a light ring-spot in the cell-end, and the light yellowish-grey macular chains beautifully contrast with the dark ground-colour. Femora and tibiae are covered with dense and long hair. Discovered by ROBERTO MUELLER in Zacualpan.

H. fuscosa Jones (58 d). A small species recognizable by the variegated thorax, the brown forewing *fuscosa*, mixed with red, and the black hindwing which is narrowly yellow only at the costal margin. Head orange, collar yellow, patagia with a black shoulder-dot, forewing with red spots on the blackish-brown ground, along the costal margin, proximal margin, and border. South Brazil.

H. sthenia Hmps. (58 d). Dark yellowish-brown, forewing with light spots bordered dark, along *sthenia*, the costal margin and before the border, and 2 larger ones in the middle and at the end of the cell of the forewing; at the proximal margin small dark spots. Hindwing diaphanous light grey, towards the apex brownish. Rio Songo.

H. umbrosa Hmps. (58 d). Larger, dark nut-brown, forewing only with few punctiform spots round *umbrosa*, the cell-end and before the border, of which only the apical ones are distinct and dark. Hindwing towards the margin still darker brown with a blackish discal spot. South Brazil.

H. interstriata Hmps. (58 d). Small, body dark brown, forehead yellowish-white. Forewing light *interstriata*, greyish-brown, the margins suffused with yellow. In the middle of the cell, in the cell-end and below the cell whitish diffuse spots. Hindwings dull diaphanous white. South Brazil.

H. acuta Hmps. (58 d) is much larger than the preceding, forewings greyish brown, the margins *acuta*, intensely yellow; unmarked except an antemarginal, rather irregular row of dots. Hindwings similar, greyer, the subterminal dots somewhat larger, forming a large hook at the end of the submedian fold. South Brazil.

H. setosa Rothsch. (58 e). One of the smallest species of the genus, quite bone-white with cloudy *setosa*, brown darkening along the costa, in the median area and at the border of the forewings, and a black dot encircled light at the cell-end. In the hindwing the apex, a small antemarginal spot and the inner-marginal area are brownish. Abdominal dorsum yolk-coloured except the whitish apex. Peru.

- ochracea*. **H. ochracea** *Mschlr.* (58 e). Only one ♀ is known from Surinam. Head and thorax orange, abdomen paler. Forewing orange, median area with 4 finely undulated lines; 3 thin postmedian lines are in the costal part of the wing distally curved, then proximally; at the border traces of a series of small tooth-like spots; hindwings pale yellow. Expanse: 40 mm.
- striata*. **H. striata** *Jones* (58 e) is considerably larger than *ochracea*, head and thorax pale yellow, only the abdomen orange with rows of punctiform spots above and laterally. Wings pale bone-white, the forewing at the costa and base tinged sulphureous, in the median area numerous, mostly double transverse lines which, however, are interrupted at the median. In the apex light small spots surrounded by dark, before the middle of the border dark dots, and in the anal angle a dark ring. Hindwings diaphanous dull whitish. Castro (Paraná) in Brazil.
- bipartita*. **H. bipartita** *Dgn.* (58 e) has still broader wings than *striata*, an ochreous-yellow body and pale bone-coloured wings. Forewing scantily strewn with small brown spots, the costal and proximal margins as well as a ray proceeding from behind the base to the apex, where it is broken up into spots, wood-coloured. Hindwing with a brown apical margin and some spots before the distal margin. Brought by A. H. FASSL from Mt. Tolima in Colombia.
- falacroides*. **H. falacroides** *Rothsch.* (58 f) somewhat resembles *bactris falacra* in its shape. Colouring quite greyish-brown, forewing with a dark cell-end dot and large, pointed sagittiform or hook-shaped spots pointing towards the base. Hindwing towards the costa lighter. Peru and Ecuador. — **affinis** *Rothsch.* (58 f) is perhaps only a form of the preceding, in which the arrow-head-like spots are partly shortened, though increased, in addition to them white longitudinal spots in the cell and above the proximal margin. Peru.
- aurantiaca*. **H. aurantiaca** *Rothsch.* (58 e). Dirty ochreous-yellow, forewing tinged reddish with numerous, bone-coloured cuneiform spots, arranged in oblique rows, in the distal part of which there is mostly a dark dot; behind the lower cell-angle a darker streak. The markings are extinct, dull and not easy to recognize. Abdominal dorsum black, in the posterior part yolk-coloured. The hindwing in specimens from Colombia and Venezuela is blackish, in the costal area light ochreous-yellow, whereas a ♂ which is said to originate from Espiritu Santo has quite black hindwings.
- cedon*. **H. cedon** *Drc.* (= *venezuelensis Rothsch.*) (58 f) entirely resembles *aurantiaca*, but instead of the light cuneiform spots there are blackish dots scattered across the forewing. Panama, Venezuela, South Brazil and Peru.
- vangetta*. **H. vangetta** *Dyar* (58 f). This species peculiarly resembles in its exterior the Noctuid *Leucania unipuncta* flying in the same district, not only by the shape and colouring, but also by the oblique streak from the apex of the forewing, the cell-end mark of all the wings and the dark macular band before the border of the hindwing. The under surface is quite unicolorously yellowish dusty grey, only the median dots and oblique streaks from the apex of the forewing are indicated by some small dark scales. Hitherto only discovered near Misantla in Mexico by ROBERTO MUELLER, from where we figure it.
- hadenoides*. **H. hadenoides** *Rothsch.* (58 e) also derives its denomination from an exterior resemblance to a Noctuid. Quite unicolorously dark brown, the forewing with a blackish dot at the lower cell-angle and dispersed hook- and ring-shaped spots. Larger than the preceding. Amazon.
- mancina*. **H. mancina** *Schs.* is allied to *hadenoides* (58 e); body greyish-brown, abdominal dorsum brownish-grey. Forewing loam-brown, with some dark brown strewing and lighter shading, forming an irregular antemedian band bent outward. Behind the middle a macular row likewise bent outward below the cell, and before the border internerval diffuse spots bordered with black. At the cell-end a small yellow spot encircled by black; hindwings dark brown with a broad whitish-yellow costal margin. 39 mm. Guatemala (Cayuga).
- jonesi*. **H. jonesi** *Rothsch.* (58 e). Size between that of the two preceding, colouring pale ochreous-yellow strewn darker, in the cell a dull darker encircled cordiform spot, at the distal cell-angle a spot, in the marginal third a subterminal row of ellipses being shaded at the poles. Castro (Paraná) in Brazil, discovered by D. JONES.
- lurida*. **H. lurida** *Edw.* (= *otho Brn. & Mc. D.*) (58 f, g). Immediately recognizable by the long-extended forewings being particularly pointed in the ♂. Thinly scaled, yellowish dusty grey, ♂ almost unmarked except a fine cell-end dot and a nebulous stripe from the base to the apex, ♀ with numerous pale ochreous ellipses and hooks. Abdomen in the ♂ above blackish. Mexico and Colombia. In its exterior the butterfly somewhat resembles certain reed-butterflies; the larva, in any case, lives on reed-like Monocotyledons.
- nonagrioides*. **H. nonagrioides** *Rothsch.* (58 h). The butterfly derives its name from the same resemblance as the preceding species. The markings have vanished except quite faint traces consisting of scattered, very indistinct cuneiform and oviform spots and fine dark lines on the 3 main veins and the median veins. Hindwings diaphanous bone-coloured. Venezuela, South Brazil, and Peru.
- sablona*. **H. sablona** *Schs.* (58 g) has rather the same shape as *lurida*, but the border of the forewing is somewhat straighter, the forewings themselves not quite so pointed. The ochreous brownish-grey forewings are so densely strewn with blackish atoms, that only where they are absent, the lighter ground-colour appears in the shape

of light spots arranged to bands. Hindwing diaphanous grey with dark antemarginal bossy spots. In the ♂ the strewing of the forewing is less, and the proximal part of the hindwing is suffused with dark. From Castro in South Brazil (Paraná).

H. rhomboidea *Sepp* (= *strigulosa* *Wkr.*) Likewise of an owl-like habitus, pale yellow, the forewings *rhomboidea*, finely strewn with numerous transverse striae, with a distinct cell-end mark and a characteristic, somewhat downward convex longitudinal streak from the base to the apex. The butterfly is rather variable. In *citrina* *citrina*. *Wkr.* the colour is very bright light yellow and the transverse striae are often indistinct. — **mandus** *H.-Schäff.* *mandus*. (58 g), perhaps only a form of *rhomboidea*, but recently again considered as a distinct species, has the longitudinal stripe widened to a broad band slit up at the margins. — Larva dark iron-grey, with light lateral spots, beginning from the 6th ring the dorsum is flesh-coloured, like the bogus feet and their followers. The *Halisidota*-pencils are, particularly at the anterior end, very long though thin; it lives on *Paspalum indicum*, presumably also on other Gramineae, spinning a cocoon intermixed with its blackish hair and turns into a blackish-brown pupa. From Mexico to Peru, Bolivia and South Brazil, in most of the districts not common.

H. dinellii *Rothsch.* (58 g) is allied to *rhomboidea*, but it has broader wings, always more lemon- *dinellii*. coloured than brown, the cell-end spot not very prominent, the longitudinal ray of the forewing finer, straighter. Described from Tucuman in Argentina, but before me also from the adjoining Bolivia.

H. pseudoconiata *Rothsch.* (58 h). Of a brighter and lighter yellow, somewhat allied to the form *pseudoco-* *citrina* of *rhomboidea*. With broad wings like *dinellii*, but the colouring is a purer and brighter yellow, the marking *niata*. more scanty, in the costal half of the forewing quite vanished. The spot at the lower cell-angle more distinct, but the longitudinal ray only in the apical part well preserved; above the proximal margin brownish shades. In the ♀ the marking is a little more distinct, and the hindwings exhibit small, dark marginal rings. Peru.

H. similis *Rothsch.* (58 g). Similar to *pseudoconiata*, but the longitudinal ray in the very pale bone- *similis*. coloured forewing is to be noticed also in the proximal half of the wing (on the median), and the branches of the median are brown, too, and there are brown transverse striae at the costal and proximal margins. Amazon and Peru.

H. oruboides *Rothsch.* (= *pterostomoides* *Rothsch.*) (58 g) is quite similar to *similis*, but larger, with *oruboides*. broader wings, the longitudinal ray of the forewing more equalized and besides there are so many ochreous yellow and brown hooks, spots and rings, that the bone-yellow ground colour remains only yet in the basal and marginal part and numberless cuneiform and oviform spots scattered across the disc. Peru.

H. hoffmannsi *Rothsch.* (58 k). Forewing light bone-coloured, but the costal margin and border *hoffmannsi*. brownish, and an oblique longitudinal stripe from the apex over the cell-end expands continually as far as the submedian (vein 1), enclosing in its centre small bone-white crescents. Besides small dark spots at the costal margin and border. Hindwing brownish-grey, the costal area except the costa itself and some small marginal spots bone-coloured. Peru. Described according to 1 ♂ from Pozuzo.

H. oruba *Schs.* (58 h). Forewing bone-coloured, but with very bright and irregular brown markings; *oruba*. the longitudinal ray through the whole wing, the cell-end mark sometimes distinct, sometimes absent, before the margin light, distally brown cuneiform spots. The ♀ is much less marked, beside the longitudinal ray it has mostly only dispersed small brown dots; the hindwings, showing in the ♂ mostly brown spotting before the apex and the middle of the border, are in the ♀ sometimes quite unicolorously bone-white. Colombia, South Brazil and Bolivia.

H. oblonga *Rothsch.* (58 i) is so closely allied to *oruba* that it might be a form of it, distinguished *oblonga*. by the light and dark spots on the forewings and prothorax being increased and by the longitudinal stripe through the forewing being thickened to a broad shade in the middle. Peru.

H. quadrata *Rothsch.* (58 k). Colouring and marking almost entirely as in *oruba*, but the forewing *quadrata*. much larger and obtuser. Peru.

H. quanta *Schs.* (58 i). Smaller than the preceding. Forewing in the ♂ red, in the ♀ pale yellow, *quanta*. with a brown (in the ♀ tinged yellowish-red) longitudinal stripe from the base as far as below the apex and a very slightly marked cell-end mark. Bolivia and South Brazil (Castro).

H. aurata *Jones* (58 k) likewise from South Brazil (Castro) has a darker longitudinal stripe not quite *aurata*. reaching the border. Perhaps only an aberration of *quanta*-♀.

H. lineata *Schs.* (58 i), likewise from Castro Paraná, has red-brown forewings of the tinge of *quanta*-♂, *lineata*. but the median stripe broader and bifurcating behind the cell-end, and before the border there is a row of subterminal dots; abdominal dorsum greyish-yellow. — **rosetta** *Schs.* (58 h), from South Brazil, before me, *rosetta*.

however, also from the Rio Songo (Bolivia), only differs by the dark red dorsum of the abdomen.

tanamo. **H. tanamo** Schs. (58 i). One of the few species of this genus with a red abdominal dorsum. Through the broad forewing extends a median transverse row of 4 or 5 large rings; behind it an oblique nebulous stripe and in the distal area fragments of faded ring-markings. Hindwings dirty white with yellow margins. Cuba.

batesi. **H. batesi** Roths. (58 i), unknown to me, is very variegated, body and forewings orange-yellow, thoracic dorsum dotted black and marked dark red, forewing finely striated dark and with numerous brown, somewhat irregular spots, which are concentrated behind the cell-end and in the marginal third to larger brown spots enclosing again a submarginal row of white cuneiform spots. Hindwing rosy-red with a broad yellow border and a bone-white proximal part. From Teffé (Ega) on the Amazon.

obvia. **H. obvia** Dgn. (58 i), from Guiana, is similar, but less variegated, with a dark violettish-brown abdomen, and the hindwings overshadowed with blackish. Forewing golden yellow, strewn with brown atoms which are concentrated to a postmedian band, a series of submarginal spots, a cell-end spot and a longitudinal streak from the costa behind the base as far as beyond the anal angle. Guiana.

turrialba. **H. turrialba** Schs. (58 k). Larger, otherwise like *obvia*, the abdomen above dark brown and the hindwing brown, only in the cell and behind it yellow. Forewing golden yellow with orange-red spots at the costal and proximal margins and chains of brown crescents. From the apex to the proximal margin near the base a thick, dark brown, partly expanded dentate line through the wing, almost parallel to the costal margin. Described according to a ♂ in the National Museum at Washington, from Costa Rica.

nubilosus. **H. nubilosus** Roths. (58 k). Scheme of markings rather similar as in *turrialba*, but the ground-colour is a dull white, the hindwings bone-coloured, the abdomen yolk-coloured; the undulate lines in the forewing enclose manifold white cuneiform spots. Peru.

brunnei-tincta. **H. brunneitincta** Hmps. (59 a). Forewings dull whitish, shaded with grey, brown and yellowish, with whitish, somewhat irregular embedments: recognizable by the thoracic markings, the red abdomen spotted black, and the middle of the hindwing being traversed by a band of large white spots; also below the costal margin and before the border the hindwing shows white spots. From Rio de Janeiro; certainly rare in the immediate surroundings of the town.

rusca. **H. rusca** Schs. (58 k). Likewise from South Brazil, with brick-red thoracic dorsum and forewings on which numerous, scattered, dark brown atoms, leaving some places free, form then lighter red spots, as they do in the submedian space, in the posterior part of the cell, in the distal third and at the border and proximal margin. Hindwing at the margins likewise brick-red, the interior of the wing dull diaphanous whitish. Abdomen dark greyish-brown, on the dorsum black transverse spots.

pseudomaculata. **H. pseudomaculata** Roths. (58 k). Like the preceding from South Brazil, the forewings whitish-grey, along the costal and distal margins as well as right through the disc before and behind the middle extend sulphureous macular rows, at the costal margin separated by brown costal spots; brown transverse bands near the base and before the middle. Head and thorax orange, abdomen lighter yellow than the hindwings.

ronda. **H. ronda** Jones (59 a). This species also originates from South Brazil (Castro); forewings yellowish-grey, finely strewn dark, with 6 or 7 transverse chains of rather equally large, white, ellipsoidal spots beginning at the costal margin with a large rhombic spot. Hindwings dull white, abdomen orange.

maculata. **H. maculata** Harr. (59 a). This butterfly, variable both as larva and imago, inhabits the United States of North America. The typical form is almost unicolorously golden yellow, with orange ring-chains across the forewings and pale-yellow hindwings. In the apical costal area of the forewing some small spots are encircled with brown instead of dark yellow. — *agassizii* Pack. (= *californica* Wkr., *salicis* Bsd.) (59 a) differs entirely by the spaces between the macular chains being filled up with red-brown in the whole costal- and proximal-marginal areas; from the Western States. — *guttifera* H.-Schäff. (= *fulvoflava* Wkr.) (59 a) shows the whole ground of the forewing brown and the yellow macular chains in the disc interrupted in such a way that the light yellow spots are complete only at the costal and proximal margins. Nova Scotia. — In *angulifera* Wkr. (= *alni* Edw.) from the North West States the imago being more intensely dusted with brown deviates less than the larva which shows black instead of white pencils at the anterior and posterior parts. — *eureka* Dyar from California is entirely dusted with brown, so that the marking becomes quite indistinct again, particularly the forewings are brown at the costal and proximal margins, between more yellowish-brown. *texana*. — **H. texana** Roths. from Texas is similar, but smaller and paler, the markings of the forewings still duller. — Larva black, densely covered with lemon-coloured hair which are longer at the sides. On the dorsum of the 5th to 12th rings there are 8 paired tufts of black hair, on the 4th to 10th rings there are also lateral black hair. In typical larvae the 6 *Halisidota*-pencils at the anterior end of the larva are purely white, like the long pencils

at the posterior end, too. On poplars, willows, alders and other deciduous trees. Cocoon thin, velvety, with intermixed hairs. — The butterflies are not rare in many districts.

H. caryae Harr. (= *annulifascia* Wkr., *caryae* Rothsch.) (59 a). A rather imposing, brightly coloured *caryae*. species. Forewing pale yellow, with numerous red-brown streaks which set off the veins and cross the cell. Parallel to the border there run 5 or 6 bands of diaphanous, white lustrous spots; thorax marked brown. Canada and the United States. — **porphyria** H.-Schüff., likewise from the United States, has the hyaline spots smaller, *porphyria*. very numerous and distinctly surrounded by dark. — **propinqua** Edw. (59 a) is the large and beautifully *propinqua*. marked southern form representing the species in Mexico and Central America; here the veins are very beautifully marked red, the reflecting spots are large and touch each other in the single chains. — **mixta** Neum. (= *pseudo-mixta*. *caryae* Rothsch.) is the form from Arizona; the yellow ground-colour is thickly covered with brown, and the reflecting spots are likewise yellow, so that they do not contrast so much. — **bicolor** Wkr. (= *pura* Neum.) (59 b) *bicolor*. looks quite different from all the other *caryae*-forms, but it is reported to have been bred from *caryae*-larvae. Here the hyaline spots are not surrounded by dark, but they only rest, as unsealed patches in the uniformly light yolk-coloured ground-colour, so that only at a certain exposure to light or on the darkened background they are prominent as undusted interspaces or lustrous, small reflectors. This form occurs in Arizona and Mexico, we figure it from the latter country. — Larva with a black head, venter and feet above greenish white, speckled black, on the 4th to 10th rings with tufts of long black hair, standing together above the dorsum. Rings 4 to 10 with long lateral hair-pencils; some long hairs are above the head, and at the sides there are white hair. It lives on the hickory-nut (*Carya alba*) and nut-tree (*Juglans*) and pupates in a cocoon intermixed with hair. In many places common.

H. ingens Edw. (= *scapularis* Stretch) (59 b). Thorax dark yellowish-brown, vertex, tegulae, patagia *ingens*. and a median stripe on the thoracic dorsum white, abdomen yolk-coloured, forewing olive-brown with silvery white, small reflecting spots arranged in rows, similar as in *argentata* (59 b), but the spots at the costal margin much larger, like those in the submedian space. Hitherto found only in the Rocky Mountains, in Colorado and New Mexico.

H. alternata Grt. (= *albiguttata* Bsd.) is quite similar to *ingens*, but the thorax is uniformly mixed *alternata*. with black and white, the ground-colour of the forewing is black, intermixed with small white scales, base and inner-marginal area are mostly more spotted. Mexico, Cuba.

H. argentata Pack. (59 b). Head above yellow, body yellowish white, otherwise very much like the *argentata*. preceding. Ground-colour of forewings a beautiful yellowish brown, intermixed with small white scales, the reflecting spots being arranged in straight rows are of a bright silvery white, the hindwing mostly in the disc and before the apex spotted brown. — In **subalpina** French from the Rocky Mountains the thorax is of a brighter *subalpina*. red-brown and the forewing at the costa and proximal margin so profusely covered with ochreous-whitish, that the wings are of a pale colour here. — On the contrary, **sobrina** Stretch is a more monotonous form from the Cali- *sobrina*. fornia coast, the forewings showing a uniformly deep brown ground-colour and the silvery spots being smaller. From British Columbia through the Pacific States as far as Colorado, New Mexico and Arizona.

H. andensis Schs. (59 b). As large as the preceding and also very much like it, but the spots of a *andensis*. fainter silvery gloss and somewhat diaphanous, though not hyaline. The ground-colour is profusely strewn with yellow and white atoms; hindwings hyaline, in the apical part spotted brown. Abdominal dorsum brownish. Colombia; the figured specimen from the Quindiu-Pass (Central Cordilleras).

H. affinis Rothsch. (59 b). Thorax darker olive brown, vertex, collar and patagia white, the latter *affinis*. with a thick black shoulder-dot. Abdomen yellowish-brown, with blackish hair on it. Ground-colour of the forewings uniformly dark olive-brown, the numerous silvery white macular rows somewhat irregular; a marginal row of white spots. Vera Cruz and Peru.

H. hyalinipunctata Rothsch. (59 b). The ground-colour of the forewing more sepia-brown, watered *hyalinipunctata*. with white, the spots very large, purely hyaline, so that fine writing may be legible through the wing; the macular rows straighter, more regular than in *affinis*, at the border only small fine white marginal dots. Peru, the figured specimen from Cillutimarca in Bolivia.

H. tessellaris Abb. & Sm. (= *antiphola* Walch.) (59 c). Pale ochreous-yellow, wings thinly scaled, *tessellaris*. traversed by yellowish hyaline bands, the antemedian one being broad, the postmedian one bifurcated towards the costa, the subterminal one irregularly composed of squares. Abdomen yolk-coloured. Canada and Atlantic States. — The bands may, in aberrations, vary in the shape: in ab. **antipholella** Strd. (= ab. 1 *Hmps.*) the two *antipholella*. median hyaline bands are partly or entirely confluent. — In ab. **tessellaroides** Strd. (= ab. 2 *Hmps.*) the spaces *tessellaroides*. between are of a darker tinge, and the two distal hyaline bands are connected with each other by a bridge. — **meridionalis** Rothsch. (59 e) is a large form from Mexico, which we figure from Mexican City; here the hyaline *meridionalis*.
lis.

- bands are so much expanded that there remain only very narrow spaces between, which are besides of a brownish colour in the costal area and bordered there with a much thicker black colour than in the *tessellaris* of the United States. This form is described according to specimens from Orizaba, in which the space between the median bands is narrowed to a dot at the proximal margin, the thorax exhibiting no green colour, which is not the case in specimens from the neighbourhood of the city of Mexico, but which seems to us not to be sufficient to establish a new name, particularly since the width of the bands of the forewings varies very much individually, and may even differ on the two surfaces of one specimen. — The name for the form ***harrisii* Pack.** is, as HOLLAND already states, neither sufficiently founded, since it only refers to a variation of the larva (the anterior pencil being white instead of black). — Larva ochreous with yolk-coloured dense tufts on the sides and above, which are quill-like closed up on the dorsum. On the 3rd ring there are 4 long pencils pointing forward, on the 12th ring two pointing backward, partly accompanied by long yellow bristles; in the larval aberration of *harrisii* the pencils are, as mentioned above, white instead of black. It lives on different foliage-trees, especially on acorns, beeches etc., and turns in a web mixed with larval hair into a sepia-brown pupa yielding the imago after 3 or 4 weeks. The butterflies are mostly not rare and like to come to the lantern.
- cinctipes.* **H. cinctipes** Grt. (59 c). This species constantly differs from *tessellaris* only by the nomenclaturally used black rings on the tibial ends and foot-joints exhibited in the type, and perhaps the generally more brownish colouring, as well as the deep orange often warming into reddish of the abdominal dorsum. In various aberrations the species is distributed from Mexico to the south as far as South Argentina and is even to the south of Buenos Ayres not rare. — To the north it extends as far as Arizona, from where the ab. ***davisii* Edw.** (59 c) originates, distinguished by nearly all the dark bands being extinct, except the basal and cell-end-band of the forewing, and which may be a distinct species, occurring, however, also in other districts. — Another form is ***insularis* Rothsch.** (59 c) from Santa Lucia where, on the contrary, the transverse bands of the forewings are particularly dark and prominent, like the costal margin and proximal margin. — In ab. ***lucia* Strd.** (= ab. 3 *Hmps.*) from the same place the dark median band is connected yet with the forked band by a dark spot. — In ab. ***fumosa* Schs.** which may sometimes occur among typical specimens, the colouring is darker, particularly the hindwings are tinted brownish. — In ab. ***ata* Strd.** (ab. 1 *Hmps.*) the subterminal band is complete and sometimes connected with the marginal band. — ab. ***meta* Strd.** (= ab. 2 *Hmps.*) shows the subterminal band twice interrupted. These aberrations are neither bound to a certain locality. — The name ***meridensis* Rothsch.** (59 c), however, refers to a larger form with dark, complete and distinct bands, originating from Merida in Venezuela, from where, however, also normal though somewhat large *cinctipes* are before me. — ***tucumana* Rothsch.** (59 d) is quite a similar, likewise dark-banded, though somewhat smaller form from Tucuman in North West Argentina. *caripator* Dyar is presumably only an individual aberration from Mexico. — Larva sometimes lighter sometimes darker yellowish-brown, the tufty dorsal hair combed up to a dorsal quill, sometimes lighter yellowish-brown, sometimes chocolate-coloured; the pencils at the anterior and posterior ends long, whitish, head red-brown; it lives on Hibiscus, Coccoloba floridana, unifera, and other plants and changes into an oviform, solid cocoon. The butterfly is common in many districts, especially in the south.
- oslari.* **H. oslari** Rothsch. (59 d) is allied to *tessellaris*, but still paler, and in the distal part of the wing all the band-markings are blurred. Colorado.
- schausi.* **H. schausi** Rothsch. (59 d) greatly resembles *cinctipes*, but it is easily recognizable by the uninterrupted submarginal band, the paler total colouring, particularly also on the body; the hindwings are diaphanous whitish, with a yellow tinge at the proximal margin and border. From Mexico through Central America to Colombia. — ***pallida* Rothsch.** (59 d) shows a clear unmarked area from the subbasal region almost to the middle of the wing, and the band through the middle of the wing is uncoloured except a small ochreous-yellow costal spot. From Mexico to Callão in Peru. — ***braziliensis* Rothsch.** (= *ruscheweyhi* Dyar) shows, like *oslari* (59 d), in the distal part of the forewing the borders of the transverse bands quite blurred, but the costal and proximal margins are of a bright ochreous-yellow colour; South Brazil and Argentina.
- steinbachi.* **H. steinbachi** Rothsch. (59 d) is easily distinguished from the preceding by the much darker brown tinge of the forewings, particularly the transverse bands and the basal part being dark brown. Collected by GIACOMELLI in La Rioja in North West Argentina.
- interlineata.* **H. interlineata** Wkr. (= *jucunda* H.-Schäff.) (59 c) has the bases of the wings and the spot around and above the cell-end conspicuously dark brown, the subterminal transverse band often being entirely absent; Mexico, Central America and Peru. — In ***intensa* Rothsch.** (59 c), a much larger form from Costa Rica and Venezuela, which we figure from the Volcano Irazu, but which is before us also from Bolivia, this subterminal intermediate band is still present, but sometimes extremely thin.
- underwoodi.* **H. underwoodi** Rothsch. (59 c), in contrast with *interlineata*, has a distinct, dark submarginal band; the costal spots are yellowish-red narrowly bordered with black, and the median band is so broad that it almost or actually touches the cell-end spot below the costa; besides the abdomen beneath is spotted black. Mexico,

Costa Rica, Peru. — *instabilis* Dyar from Cuernavaca in Mexico shows the subterminal band between the lower radial veins and at the proximal margin reduced to a dot at the vein. — *orientalis* Rothsch. from Trinidad, Guiana and Brazil is smaller and paler, particularly the median band in the ♂ is scarcely coloured. — *modalis* Dyar is a form from Venezuela, in which the wings are yellowish, the bands of the forewings ochreous-brown.

H. fuliginosa Rothsch. (59 e) is at once recognizable by the dull brown colouring of the wings and the abdominal dorsum being black in the ♂, very dark yellowish-brown in the ♀. Beneath the body is orange, particularly the thorax. Mexico; the figure according to a specimen from Orizaba.

H. atra Drc. (59 e). ♂ deep sooty brown, ♀ somewhat lighter; from *fuliginosa* it differs by the absence of the terminal band of the forewing, where also the subterminal band is reduced to spots at the costa, proximal margin and between the radial veins. The hindwings of the ♂ bear a silky reflection in the sunshine. Abdomen blackish-brown, in the ♀ posteriorly yolk-coloured. Mexico and Guatemala, the figured specimens from Misantla.

H. bricenoi Rothsch. (59 f). Larger than *atra*, easily recognizable by the bands in the apical third of the forewing in both sexes being completely reproduced by the marking of their borders, though not by the colorial difference. Known only from Merida in Venezuela, from where also the figured specimen originates.

H. masoni Schs. (59 g). A very fine species. The bright orange-red forewing shows a straight, greyish-yellow median band traversed by the thick black veins, a similar demi-band at the cell-end and the same colours in the basal and marginal areas; thorax fiery light red. Beneath the median band, cell-end spot and base of the forewing are marked black, the wings otherwise golden yellow. Known only from Mexico. — The most peculiar distribution of the colours somewhat reminds us of *Anaxita decorata* occurring in the same district.

H. nero Weym. (59 f) and the following species deviate very much from the genus by their colouring, and *nero* was also described as *Amastus* and only placed to *Halisidota* by HAMPSON. Black, abdomen bright red, its base above black. From Joinville in Brazil.

H. dukinfieldia Schs. (59 f) is like *nero*, but the abdomen black, only the base and anal part red, the head and collar being red, too. South Brazil (São Paulo, Castro).

H. notata Schs. (59 f). Blackish-brown, head and thorax with pale yellow and purple red markings; abdomen posteriorly banded red, laterally spotted yellow. Forewing with pale yellow spots at the costal margin before, in and behind the middle, at the base of the proximal margin a faint stripe and a dot behind the middle. Hindwings whitish, margins and veins brownish, the brown at the border proximally irregularly defined; a triangular dark median spot. Size of the preceding. From Petropolis in the Organ Mountains, apparently an alpine insect and very rare.

H. triphylia Drc. (59 f) and the following species neither look like a *Halisidota*. Their ♂♂ are unknown. *triphylia* has unicolorously dark brown wings with black veins. Head, thorax, and the posterior third of the abdomen are yolk-coloured. From the Chiriqui in Panama.

H. humosa Dgn. (59 g) is slightly smaller than *triphylia*, the body quite similar in the colouring and structure, but the ground-colour of the unicolorous wings is more honey-yellow, for which reason the black veins are more prominent. The colouring and habitus somewhat recall *Pachydota striata* (55 i), *Ischnocampa nigrivena* (55 h) etc., but the ground-colour is greyer. Described from Loja, Ecuador; the figured specimen originates from the Upper Rio Negro (Colombia).

H. melaleuca Fldr. (59 g). White, neck and abdominal dorsum haired blackish-brown, forewings with pale ochreous-yellow embeddings, at the costal margin and border brown spots marked black, of which a large one is distally blackish-brown, proximally yellowish, and encloses the white cell-end spot. Hindwing in the ♀ with a dark marginal band. Beneath similar as above. From the Quindiu Pass in the Central Cordilleras of Colombia.

H. roseifasciata Drc. (59 g) and the following species also deviate considerably from the habitus of the other *Halisidota*, and both were also described as *Automolis*, though they would best form a special genus. Forewings honey-coloured with a brownish border and a yellowish-pink layer on the margins and above the middle of the wing, which however, varies greatly in the different specimens. Still more characteristic than the wings is the body: anterior part of the head, collar and abdomen orange, thorax light honey-coloured, before the abdominal end 3 narrow black transverse bands. Peru and Bolivia.

H. semibrunnea Drc. (59 g). All the wings blackish-brown at the margins, towards the base turning at first red-brown, then honey-coloured. Head, collar and base of abdomen yellowish-red, thorax light yellow, abdomen otherwise blackish-brown. Beneath the blackish-brown forewings are yellow towards the base, the apex being fiery red. Peru and Bolivia.

- rhoda*. **H. rhoda** *Hmps.* (59 g) and the following species already approach the next genera into which the genus *Halisidota* passes over without a distinct delimitation. *rhoda* is quite purple brown, the forewings with a dark cover and veins, the abdomen yellowish-red with dorsal black transverse veins. Bolivia.
- arenacea*. **H. arenacea** *Schs.* (59 h). Body yolk-coloured, forehead and metathorax light yellow, patagia with a black shoulder-dot. Wings somewhat diaphanous whitish-grey. Forewings with broad orange-yellow margins. Ecuador.
- semivitre*. **H. semivitre** *Dgn.* (59 i) resembles *arenacea*, but the wings are yellowish, almost hyaline, only the costal and proximal margins faintly honey-coloured; the shoulder-dots on the patagia are absent. Peru.
- agramma*. **H. agramma** *Dgn.* (59 i). Thorax and forewings yellowish dusty-grey strewn with small black scales. Head, costal and proximal margins honey-coloured; abdomen and hindwings dull white, the costal margin of the hindwing beneath tinged reddish-brown. Colombia and Peru.
- montana*. **H. montana** *Schs.* (59 i). Body and wings pale honey-coloured, thorax and abdomen above marked ochreous; forewing with a small dark spot at the cell-end, the costal and proximal margins tinted ochreous. Costa Rica.
- labaca*. **H. labaca** *Drc.* (59 h). Body and wings pale honey-coloured, at the costal margin, at the apical part of the border, and at the proximal margin brown spots which are much larger in the ♀ and sometimes form bands parallel to the border, sometimes also a dot at the cell-end. Mexico.
- flavescens*. **H. flavescens** *Rothsch.* (nec *Wkr.*) (59 i). Pale honey-coloured, body and forewings densely covered with a fiery reddish yellow, like the pale yellowish-pink hindwings without any real marking, only the veins somewhat more prominent. In the southern parts of New Mexico; apparently only 1 specimen known, which is in the Tring Museum. Presumably very closely allied to the following.
- margona*. **H. margona** *Schs.* (59 i). This species connects the *labaca*-group with the *Halisidota* from the group of *sobrina-distincta* etc. Body and wings of a bright yellow, head, thorax and forewings marked red with rings, chains and undulations on the forewings; in the ♂ the marking is often so fine that it cannot be well reproduced in the figure; distinct are only a dark dot at the cell-end and an inner-marginal stripe. Hindwings lighter and faintly diaphanous. Mexico, in some places not rare.
- anapheoides*. **H. anapheoides** *Rothsch.* (59 h) is denominated owing to its superficial resemblance to African *Anaphe*. Pale honey-coloured, body and margins of forewings reddish-yellow, like the veins on the forewing, and very faint traces of a submarginal stripe. From the Chiriqui in Panama.
- rufocinnamomea*. **H. rufocinnamomea** *Rothsch.* (59 h) is like the preceding species, but the forewing somewhat duller and more diaphanous and without the red-yellow veins. Peru.
- iridescens*. **H. iridescens** *Schs.* (59 h). Quite pale yellow, the wings diaphanous, with a black dot behind the cell of the forewing and one before the middle of the border on the hindwing. Thorax tinged yolk-coloured. The wings exhibit a greasy silky lustre. Venezuela, Peru.
- pallida*. **H. pallida** *Schs.* (59 i). Here the wings are also diaphanous, quite thinly scaled, but dull yellowish-grey. Body brown, tinged yellowish; on the patagia 2 shoulder-dots, on the abdomen black lateral dots. Ecuador, Peru and Bolivia.
- ordinaria*. **H. ordinaria** *Schs.* (59 h). Much more densely scaled than the preceding, forewings dark red-brown, like the thorax, hindwings diaphanous whitish-yellow, abdomen posteriorly yolk-coloured, beside the lateral dots also transverse spots on the dorsum of the abdomen. From Petropolis in the Organ Mountains.
- melanoproctis*. **H. melanoproctis** *Hmps.* (49 a). Body dark brown, head and prothorax reddish-yellow, forehead white; abdomen posteriorly white-haired. Wings hyaline, only the marginal area of the forewing dark brown with a subterminal chain of orange-red crescents. Costal and proximal margins of all the wings tinged yellowish-red. From Peru.
- picata*. **H. picata** *Rothsch.* (49 a). Size and shape of the preceding, but the body quite whitish, on the patagia and abdominal end marked dark. Forewing diaphanous whitish, only beyond the middle, the apical half and the proximal margin broadly suffused with brown; a white, antemarginal undulate line; the border behind it broadly rusty-red. Peru.
- ockendeni*. **H. ockendeni** *Rothsch.* (49 a). Size and shape of the preceding, but the hyaline forewing in the distal half speckled blackish-brown, border tinged yellow. Abdomen yolk-coloured. Peru.
- leria*. **H. leria** *Drc.* (49 a). Thorax brown, abdomen blackish. Forewings thinly scaled, grey, at the base and margins suffused with a brownish yellow, all over strewn with black atoms. An antemarginal chain of light crescents, the border behind it yolk-coloured. Hindwings dirty diaphanous white. Ecuador.
- semifulva*. **H. semifulva** *Drc.* (49 a). Body whitish, forewings hyaline dull white, distal half suffused with grey, a broad, light yellow marginal band is proximally defined in small arches against the dark colour of the wing; at the border dark vein-dots. Peru.

H. maasseni *Rothsch.* (49 a) greatly resembles the preceding, with narrower wings, of a duller tinge, *maasseni*. the thorax and abdomen ochreous. Forewing with a nebulous undulate stripe before the lighter border, which exhibits a dull brownish not light yellow layer, and with a dark cell-end. Peru.

H. tolimensis *Rothsch.* (49 b) already looks entirely like a *Hemihyalea*. It has diaphanous forewings *tolimensis*. very scantily scaled brown, the only marking on them consisting of a hyaline white, scarcely prominent, sub-marginal undulate line and of a feebly dark cell-end mark. The species is easily recognizable by the entirely white head contrasting brightly with the brown thoracic dorsum. Abdomen again covered with lighter hair. Colombia; the figured specimen taken by A. H. FASSL on Mt. Tolima at an altitude of 3200 m.

H. conspicua *Maass.* (47 f). Body dirty brown, wings dull hyaline, in the disc diaphanous, the margins *conspicua*. smoky dark and ochreous. Entirely like a *Hemihyalea*. Peru.

H. vitreata *Hmps.* (49 b). Body dark brown, shoulders marked black, abdominal dorsum tinged *vitreata*. yellowish-red except the black apex. ♂ wings quite hyaline, only the costal margin of the forewing faintly yellowish. The ♀ has the margins of the forewing tinged yellowish-red, the distal part being faintly strewn dark, the hindwings pale reddish ochreous. Peru.

H. leda *Drc.* (49 b). One of the largest species. Body and wings brownish ochreous, in the disc the *leda*. wings are diaphanous. Through the distal part of the forewing extend 2 transverse rows of small, indistinct, dark dots. Blackish dots are also on the patagia, one at the shoulder, one at the apex. From Dominica.

88. Genus: **Psychopasma** *Btlr.*

One medium-sized species with hyaline wings, described as *Halisidota*, was placed into this genus and is at once discernible by the different contours of the apical part of the forewing, where the border is gnawed out below the apex, which process is repeated, though in a less degree, above the middle of the border. This is the case in both sexes and is accompanied by a somewhat deviating course of the subcostal veins. The species is widely distributed and nearly everywhere common.

Ps. erosa *H.-Schäff.* (= *albidator* *Wkr.*, *vitripennis* *Wkr.*) (49 b). Wings hyaline, only the margins *erosa*. and veins in the forewing ochreous-yellow, marked blackish-brown; particularly conspicuous is a blackish-brown costal spot above the middle of the cell. Numerous small dots between it and the base of the wing, 2 black parallel streaks above the distal half of the proximal margin and brown bordering of the distal-marginal part below the apex, particularly at the excised place. From Mexico through Central America and Brazil to Peru, nearly everywhere common.

89. Genus: **Exemasia** *Dyar.*

This genus was established for one quite unicolorously pale yellow butterfly from Mexico, exhibiting the size and habitus of a *Halisidota*, but with very densely and long-pinnated antennae reminding us of an *Antarctia* or *Palustra*. It seems to be allied to those (resp. the *Euchaetias*) and *Apantes* by the tufted head and the fleece-like hairing of the thorax.

E. ochropasa *Dyar* (48 c). Quite pale yellowish-white. Body, wings, antennae and legs quite uni- *ochropasa*. colorous. Recognizable by very long hairy fringes on the femora and tibiae of the ♂. I do not know the ♀; the figured specimen from Mexico.

90. Genus: **Hemihyalea** *Hmps.*

This genus contains 36 forms and is allied both to the *Halisidota* and the *Amastus*. The wings show throughout a very scanty scaling, sometimes even none whatever, and the species are therefore very difficult to discern; nothing is known of their habits; nearly all the specimens known are presumably taken at the lantern to which the insects come flying rather clumsily and on which they run about awkwardly with their long legs and heavy posterior body. Proboscis strong, palpi below haired like a brush, the third joint not stunted. Antennae long like those of nearly all the *Phegopterini*, in the ♂ also with rather long double pinnae. Abdominal dorsum almost invariably glaring red or orange, in the ♂ often with distinctly projecting clenched appendages. In the forewing the two first subcostal veins rise before the cell-end, the footstalk of the 3rd to 5th is long; the two lower radials come from one dot of the lower cell-angle; in the hindwing they have a short footstalk. Only 3 species reach the southern part of the United States, the others inhabit Tropical America to the south of Mexico.

- subtenuimargo.* **H. subtenuimargo** *Rothsch.* (49 c). Wings hyaline, except the margins, the apex very brownish. Costal and proximal margins with a yellowish-brown stripe, the border with a proximally indistinct, narrow, dark brown marginal band. The border of the hindwing narrow yellow; head and thorax dark brown, forehead whitish, abdomen vermilion. Taken by FASSL on Mt. Tolima in Colombia.
- brunnescens.* **H. brunnescens** *Rothsch.* (49 d) is quite similar, but the brown distal margin of the forewing is broader, the costal stripe very narrow, the hindwing in the proximal half rosy. Colombia and Peru.
- fusca.* **H. fusca** *Rothsch.* (49 c) likewise entirely resembles *subtenuimargo*, but the brown border of the forewing is narrow, towards the hyaline ground of the wing more distinctly defined, and besides the base of the forewing is broadly brown. In typical specimens the head and thorax is of a very deep dark brown; — in the form **peruviana** *Rothsch.* from Carabaya in Peru the head and thorax are of a lighter brown. — **colombiana** *Rothsch.* from Bogotá in Colombia has the margins of the wings paler, too, besides the head and thorax.
- ergana.* **H. ergana** *Dgn.* (49 c). In this somewhat smaller form the whole wings are tinged yellowish, head, prothorax and patagia are ochreous yellow, mesothorax and the whole abdomen rosy-red. From Colombia and Venezuela to Peru and Bolivia.
- debilis.* **H. debilis** *Rothsch.* (49 c). Also here the wings are quite yellowish, at least the veins yellow also in the hyaline ground of the wings, but the apical part of the forewing is darkened and the abdomen, which is of a bright red nearly in all the other *Hemihyalea*, is here yolk-coloured, above often yet covered with grey hair. Before me only from Merida (Venezuela).
- tenuimargo.* **H. tenuimargo** *Dgn.* (49 c). Entirely like *subtenuimargo*, but smaller, the wings clearer, without the dark border, the terminal third of the abdomen, however, dark brown. Colombia.
- parergana.* **H. parergana** *Dgn.* (49 d). In this species the forewings are on the whole not so hyaline as in the preceding, but slightly darkened by red-brown, particularly at the margins, round the cell-end of the forewing, at the proximal margin and base of the forewing; on the forewing a whitish, antemarginal, undulate line. From Colombia; Tolima, Quindiu Pass.
- erganoides.* **H. erganoides** *Dgn.* (♀ = *orientalis Rothsch.*) (49 d). Head and thorax of a bright red-brown, abdomen vermilion, the wings quite hyaline, but with yellowish-pink margins. Venezuela.
- argillacea.* **H. argillacea** *Rothsch.* (49 d). Entirely like *erganoides*, but the head and thorax of a bright yolk-colour. Found in the Gold Mountains in Oregon, reported also from Guatemala.
- vitreata.* **H. vitreata** *Rothsch.* (49 c). Almost exactly like *debilis*, also with a dull yellow abdomen, but the wings of a purer hyaline, only the proximal half of the hindwing more intensely yellow; discernible by the bright white upper head and collar. Mt. Tolima in Colombia.
- hyalina.* **H. hyalina** *Dgn.* (47 g). Described from Loja in Ecuador, but our figure according to a specimen determined as „*hyaline Dgn.*“ by DOGNIN himself, but having been captured by FASSL on Mt. Tolima at an altitude of 3200 m. Wings quite purely hyaline, the margins and body light yellow, marked whitish.
- vitripennis.* **H. vitripennis** *Hmps.* (= *hyalina Drc. nec Dgn.*) is quite similar, though smaller, the hairing of the abdominal dorsum more ochreous yellow, the margins of the wings fine whitish. Mexico (Guerrero).
- alba.* **H. alba** *Drc.* (49 d) is quite similar, but the body and the margins of the wings white, prothorax and abdominal end very little marked greyish-brown. Size of *hyalina Dgn.* Mexico and Central America.
- cornea.* **H. cornea** *H.-Schöff.* (49 c). The ♀ entirely like *alba*, but very much smaller; the ♂ has a somewhat more yellowish border of the forewing with traces of a whitish, undulate subterminal line, and the dorsum of the abdomen tinted red. Colombia and Venezuela.
- daraba.* **H. daraba** *Drc.* from Mexico was reckoned to *cornea*, but it has well developed brown costal spots at the costal margin of the forewing. Mexico (Jalapa).
- rhoda.* **H. rhoda** *Drc.* (= *fuscescens Rothsch.*) (49 c) is like *daraba*, but the forewings are uniformly tinged reddish-brown, and the abdomen is above red-haired. Mexico and Central America. — ab. **hidalgonis** *Dyar* are specimens with very dull traces of light transverse bands on the forewings.
- testacea.* **H. testacea** *Rothsch.* (49 c). The ♂ differs from *cornea*-♂ by the absence of the whitish subterminal macular chain of the forewing; the ♀ shows the forewings thinly, though uniformly covered with red-brown. Mexico and Central America.
- annaria.* **H. annaria** *Dyar* differs from *testacea* only on the forewing by an antemarginal row of quite obsolete, sometimes scarcely distinguishable, small dark rings with light pupils. Costa Rica.

H. ochracea *Rothsch.* (49 e) has likewise as *testacea* a dark ochreous tinge on the forewing exhibiting *ochracea*, dull light spots at the costal margin and in the disc. Mexico, Panama.

H. mansueta *Edw. nec Drc.* (49 g) has on the forewing distinct transverse bands formed of chains *mansueta*, of spots. Hindwing at the apex brown, a part of the proximal margin is tinted pink. Mexico and Costa Rica; the figured specimen is from the Volcano of Irazu. — *ab. niger ab. nov.* (49 f) is an entirely black form occurring *niger*, on the Volcano of Irazu beside genuine *labecula* and somewhat recalling *melas*, from which, however, it differs by the forewing being black in the ♂ and by the veins.

H. battyi *Rothsch.* (49 g) is much larger than the preceding, the wings being but very slightly *battyi*, transparent. Forewing red-brown with transverse chains of yellow spots and a broad ochreous-yellow antemedian band. From Colombia. — In the form *oligocycla form. nov.* (49 g) from the Irazu in Costa Rica the antemedian *oligocycla*, band is absent, and the small spots of the other transverse bands of the forewing are so much reduced that they are no more contiguous.

H. edwardsi *Pack.* (= *translucida Wkr.*, *quercus Bsd.*) (49 f) is the largest species. The wings are *edwardsi*, rather hyaline in the disc, but at the costal and proximal margins of the forewing we notice distinct spots of a yellowish-pink tint representing the beginnings and ends of transverse bands more or less distinctly running through the forewing. California and Oregon.

H. labecula *Grt.* (49 f) is very similar to *edwardsi*, just a wee bit smaller, but the spots at the costal *labecula*, and proximal margins of the forewing are less distinct, the whole insect greyer, also the hindwing not of such a bright pink tinge as in *edwardsi*. Colorado and New Mexico. — The form *mansueta Drc. nec Edw.* (49 f) is much *mansueta*, larger, as large as *edwardsi*, but almost without any trace of a pink tinge on the wings which are light whitish-yellow, intermixed with a greyish brown, with distinct dark spots at the costa and proximal margin. This form is known from Mexico.

H. splendens *Hmps.* (49 g) was formerly regarded as a form of *labecula* which it resembles extra- *splendens*, ordinarily, in fact, except the thorax being more distinctly marked dark and the abdomen being posteriorly decorated with dark transverse bands. The spots on the forewing are also more distinct than in *labecula*, though not so distinct and dark as in *mansueta Drc.* — The 3 latter forms are probably not in all cases distinctly separable, particularly not in the much flown specimens, just like *rhoda*, *daraba*, *testacea*, and *annaria* which are merging one into another.

H. euornithia *Dyar* (49 h) from Guerrero in Mexico is much smaller, the forewing is dark brown, *euornithia*, intermixed with white bands and spots.

H. nimbipecta *Dyar* (49 g), from the same district, has a much darker forewing through which but *nimbipecta*, slightly lighter, not white transverse bands extend, with a faintly lighter basal part. The hindwing, however, is more intensely tinted pink, and the imago is larger, almost like *splendens*.

H. xanthosticta *Hmps.* (49 h) is dark brown, thinly scaled though without any really hyaline places. *xanthosticta*, Forewing with 2 transverse (antemedian and postmedian) chains of yellow spots, and a subterminal undulate shade; abdomen orange. Much smaller than *nimbipecta*. Ecuador and South Brazil.

H. diminuta *Wkr.* (49 h) is quite similar, though of a lighter colour, the hindwing more diaphanous, *diminuta*, and the two chains of yellow spots on the forewing are more faded. South Brazil.

H. utica *Drc.* (49 h) from Mexico, like the two preceding species, differs rather much from the total *utica*, character of the *Hemihyalea*, it is of a more slender structure, with narrower wings and an almost straight margin of the hindwing. Forewing densely striated and dotted black, traversed by dingy white, densely strewn bands, an angular one of which is situate near the base, a shortened one at the cell-end, and another one before the marginal third.

H. melas *Dgn.* (49 h). Head, body, and forewing uni-coloured dark brown. Hindwing diaphanous, *melas*, in the ♂ white, in the ♀ brown. Colombia and Peru. — This species presumably hardly belongs to this genus, since it differs by its very clumsy structure and relatively shorter wings and antennae, as well as by the absence of a lower discocellular, provided the figure in HAMPSON's Catalogue, which we copied, be correct. The species is not before me; the ♀ which DOGNIN described as *Opharus melas*, is in his collection, whilst the type of the ♂ is in the National Museum at Washington.

91. Genus: **Amastus** *Wkr.*

This genus, exhibiting mostly large imagines of a clumsy body and with thinly scaled wings, numbers to-day about 70 forms all of which are confined to Tropical America, not a single-form reaching anymore to the United States. It approximates the *Hemihyalea* to such an extent that some species fluctuate between the two genera, and their difference of the upper median branch of the forewing rising in *Amastus* nearer at the lower cell-angle, in *Hemihyalea* more remote from it cannot be relied upon, since this distance varies a great deal in the single species of a genus and even in some species (*ochraceator*, *aconia*) individually. Like the

Hemihyalea, also the *Amastus* are rather uniformly built imagines with mostly very plain colouring and marking and are for this reason also very difficult to ascertain. Although great numbers of specimens from this genus were brought to Europe by BRICENO from Venezuela, by GARLEPP from Peru, and by FASSL from Colombia, yet this material only refers to but few species, and about many others there still prevails a certain haziness. — As the essential mark of distinction of the genus we may mention the mostly very large male genitals by which they approximate the *Hemihyalea*, and the frequently extraordinarily long antennae resembling those of the *Opharus*. The abdomen almost invariably shows a distinct premonitory colour being orange-red or crimson and is often laterally decorated with rows of variegated rings, frequently also the clasping-organ projects distinctly at the end of the abdomen and is separated from the coloured part of the abdomen by scaleless chitinous plates. As to the habits and early stages nothing has become known to me except that the imagines come to the lantern in the evening, sometimes on certain swarming evenings in great numbers and often rather late.

- albipuncta*. **A. albipuncta** Hmps. (47 a) is one of the most beautiful species with dark brown, blackish-banded forewings recognizable by the red-marked head and collar, and snow-white dots on the frons, dorsum, thoracal and abdominal sides; abdomen purple orange. From Venezuela to Peru and Bolivia. The figured specimen from the Rio Songo.
- suffusa*. **A. suffusa** H.-Schäff. is quite similarly coloured as *albipuncta*, but instead of the dark bands of the forewing there are whitish, often double chains of crescents, and the mesothorax is vermilion. In typical *suffusa*, as HERRICH-SCHAEFFER figures it from Venezuela, the head and thorax are in front dark brown; — in the *orosiana* form **orosiana** form. nov. (47 e) of which numbers are before me from the Volcano of Irazu in Costa Rica, the head and prothorax are yellowish-grey, with an orange, black-edged collar-marking on the tegulae and patagia; the subterminal chain of small crescents on the forewing is somewhat more irregular, since the small luna between the upper radial branches projects farther towards the base. — In a third, very similar form, **hampsoni** Rothsch., from Paramba in Ecuador, the subterminal chain of small lunae is as in *orosiana*, but the wings exhibit brighter colours and markings, the thorax has a dark brown ground-colour, and the abdominal dorsum is of a deep hemochrome. — Apparently not rare.
- affinis*. **A. affinis** Rothsch. (48 a) from Ecuador and Peru is quite similar to *suffusa*, chiefly different by the subterminal line not being deeply dentate, but only slightly undulate and separating a bright red-brown marginal band from the grey, brown-banded ground of the wing.
- formosana*. **A. formosana** Schs. from El Saltadilla in Argentina has the size of *suffusa orosiana* (47 e), in the forewing the dark transverse bands are so broad that they are confluent at the costa and proximal margin and leave only two bands of the ground-colour between them, the proximal one of which is band-shaped before the middle, the distal one Y-shaped behind the middle; the latter is confluent with the subterminal chain of small lunae behind the cell-end. The type is in the National Museum at Washington; I know the species only from HAMPSON's figure which was made according to a somewhat rough draft.
- ambrosia*. **A. ambrosia** Drc. (47 a) is dull earth-coloured brown with almost yellow hindwings and a crimson abdomen. The forewing is not banded, but coarsely striated, only before the distal margin there is a dentate transverse stripe separating the lighter reddish marginal part from the darker disc. Colombia to Ecuador.
- thermidora*. **A. thermidora** Dgn. is one of the largest species with very broad, dark red-brown forewings crossed by 3 narrow transverse bands: a subbasal arcuate one, a median dentate band across the cell-end, and a sharply dentate antemarginal band; the dark hindwing exhibits light antemarginal crescents. From Loja in Ecuador. — A similarly marked form, though with narrower wings and a light striated ground-colour was captured by A. H. FASSL on Mt. Tolima in Colombia, at an altitude of 3200 m; I denominate it **peralta** form. nov. (47 a).
- volcancita*. **A. volcancita** Dgn. (48 a), founded upon a ♀ from the Quindiu Pass, which was likewise captured by A. H. FASSL, is very closely allied to the preceding, particularly to the form *peralta*; but the forewing is so much intermixed with light striae that the transverse bands disappear, except faint traces, and only round the cell-end there is a broad light spot.
- mesorhoda*. **A. mesorhoda** Wkr. (47 b) is like the preceding similar to *ambrosia* Drc., but the shoulder-covers are proximally edged with white, the abdomen is blackish-brown beginning from the 4th ring. The forewing is more equably blackish-brown with a red-brown marginal part being defined by a regular arcuate line; hindwing darkened, margined with yellowish. Colombia.
- phaeosoma*. **A. phaeosoma** Hmps. (47 b) is very similar to *mesorhoda*, but the forewing is more intensely striated light, the marginal area is not so light red-brown, and the abdomen is uniformly greyish-brown, only very feebly tinted red-brown.
- erebella*. **A. erebella** Mssn. (47 a) is smaller than the preceding; forewing sepia-brown, in the disc somewhat diaphanous, feebly intermixed with yellowish-brown striae. Abdomen and thorax dark red-brown, towards

the base above haired pinkish-red. Hindwing ochreous, in the disc diaphanous, at the margin brownish. Recognizable by the antemarginal band being more flatly undulate. Colombia to Ecuador.

A. umber *Rothsch.* (47 b). Head, thorax and forewing chestnut-brown, the latter with very feebly *umber*. lighter bands. Hindwing diaphanous chestnut-brown with darker margins; abdomen above miniate, the apical part warming into a golden yellow. From Merida in Venezuela.

A. paramensis *Dgn.* (48 b) is much larger than *subterminata* (p. 421), very similarly coloured, but the *paramensis*. forewing is more brightly striated light, and the subterminal band is just a bit lighter than the ground-colour. It is twice undulated, but at the anal angle about just as broad as at the costa, whilst in the preceding it is here not half as broad as at the costal margin. Colombia.

A. tolimensis *Rothsch.* (48 b) is quite greyish-brown, tinted yellowish-brown, the forewing almost *tolimensis*. unmarked, only with a yellowish brown, not undulate, but a slightly curved subterminal band. Hindwing in the centre lighter whitish. Captured by FASSL on Mt. Tolima in Colombia.

A. rufator *Wkr.* (47 b). Thorax and forewing monotonously deep red-brown, the subterminal line is *rufator*. light, undulate, proximally shaded with dark. Colombia.

A. rufescens *Rothsch.* (48 a) is quite similar to *rufator*, the forewing is almost exactly alike, darker, *rufescens*. but the hindwing is not tinged yellowish as in *rufator*, but pink, and the abdomen is here hemochrome. Peru. — ab. **rothschildiana** *Strd.* is a specimen from Peru in the Tring Museum, in which the subterminal band of *rothschildiana*. the forewing is extinct and the dark shade at the cell-end replaced by 2 dark dots.

A. coprophora *H.-Schüff.* (48 b) has the forewing uni-coloured brownish-violet with a light, feebly *coprophora*. undulate subterminal band, the body is orange, the thorax marked violettish-grey. Colombia and Venezuela.

A. medica *Dgn.*, hitherto only known from Loja in Ecuador, is somewhat larger than *rufator* (47 b). *medica*. Thorax and abdomen above purple pink, shoulders and collar olive-yellow, forewing dark red-brown with a dark spot at the cell-end, and a postmedian light transverse band expanding into a spot at the costa and proximal margin.

A. ochraceator *Wkr.* (47 e). Body yolk-coloured, head and thorax marked greenish, forewing *ochraceator*. diaphanous tan-coloured, with a light, undulate subterminal band and a Y-shaped, broad median band. From Mexico to Bolivia, mostly common.

A. aconia *H.-Schüff.* (47 d) is very similar to *ochraceator*, but the head is all white, only before the *aconia*. eyes very finely margined with orange. Thorax white, with orange marking. Abdomen yolk-coloured. Wings quite diaphanous light tan-coloured with dark veins and dull nebulous bands. Costa Rica and Colombia to Venezuela. One of the largest species; common on the lantern.

A. persimilis *Hmps.* (47 e) is almost exactly like *ochraceator*, but the head and thorax above are marked *persimilis*. white. In the ♀ the hindwing is grey. Ecuador, Peru and Bolivia.

A. rumina *Dre.* (= *aconia Dre.* nee *H.-Schüff.*) (48 a) so much resembles the preceding that both *rumina*. the species are often found intermingled in the collections. *rumina* has still more hyaline wings than *aconia*, though they are more intensely tinged tan-coloured, the head is all white and the thorax preponderately so, the orange colour only being left on a narrow stripe on the patagia, the posterior edge of the tegulae, and a stripe on the sides of the mesothorax. Apex of ♂ abdomen black. Costa Rica.

A. genoveva *Dgn.* (47 f). Forewing almost exactly coloured and marked as in *aconia*, but at the *genoveva*. costal margin with a yellow, at the proximal margin with a brown longitudinal stripe. Easily recognized by the mesothorax and abdomen not being yolk-coloured as in *aconia*, but hemochrome. Head, prothorax and patagia white with a honey-coloured tinge; of the same colour are the sides of the abdomen. Merida in Venezuela.

A. coccinator *Schs.* (47 e). Body quite purple pink, head and thorax marked white. Forewing *coccinator*. diaphanous red-brown, the darker marginal third traversed by a submarginal band. Hindwing quite hyaline. From Colombia and Venezuela to Peru and Bolivia, apparently not rare.

A. episcotosia *Dgn.* (47 e). At once recognizable by its gigantic size as well as by the thickly dark- *episcotosia*. sealed forewing and the dark brown colouring, and by the white bands on the thorax and abdominal end. Described from Panama; the figured specimen from Orosi, the volcano of Irazu in Costa Rica.

A. elongata *Fldr.* (47 f) is very much smaller than *episcotosia*, the forewing not so dark brown, with *elongata*. a light costal-marginal stripe and light, incomplete transverse bands. Abdomen red with a yellow apex, hindwing yellowish-brown, towards the margin darker. Recognizable by the remarkably long and narrow, almost Sphingid-like forewings. Guiana and South Brazil.

- alsa.* **A. alsa** Drc. (47 d) is smaller, but with broader wings than the preceding, the forewing diaphanous chestnut-brown, with a broad, light submarginal band. The whole body is also uniformly dark red-brown, and the hyaline hindwing is tinted so. Dominica (Peru).
- pseudocollaris.* **A. pseudocollaris** Rothsch. (48 b). Forewing diaphanous brown with a blackish transverse anteromarginal stripe and dark shades in the costal area. Head and thorax marked white and orange, abdomen deep orange-red. From the Volcano of Chiriqui in Panama.
- collaris.* **A. collaris** H.-Schäff. (48 c). Forewing violettish-brown, very diaphanous with a yellowish-brown marginal area before which there is a triple arcuate light brown transverse band. Hindwing whitish hyaline. Head and thorax orange, marked white; dorsum of abdomen orange, apex of it black, laterally and behind spotted white. Venezuela, Colombia, and Ecuador to Peru.
- flavidus.* **A. flavidus** Dgn. (47 d). Forewing crossed by black transverse stripes, and with a dentate subterminal line. The subbasal transverse stripe is curved, the two median ones in the disc extinct, the postmedian stripe broad and straight. Abdomen yolk-coloured. Colombia; the figured specimen from Pacho, Eastern Cordilleras.
- maculicincta.* **A. maculicincta** Hmps. (47 d) from Bolivia exhibits on the forewing beside the dark transverse bands, before the marginal third, a curved chain of black, yellow-pupilled rings. Abdominal dorsum hemochrome, behind black and white.
- flavicauda.* **A. flavicauda** Rothsch. (48 c) is larger, lighter, instead of the curved chain of rings before the marginal third of the forewing of *maculicincta* there is a faded chain of spots, in the marginal area itself a row of small subterminal crescents. Dorsum of abdomen hemochrome, behind hemochrome. Costa Rica and Panama.
- rosenbergi.* **A. rosenbergi** Rothsch. (48 c) is similarly marked to the preceding, darker, the transverse bands of the forewing distinct and complete, the antemedian and median transverse bands are broad, in and before the marginal third one chain each of dark brown ring-spots parallel to the margin. Abdomen hemochrome. Colombia.
- antonio.* **A. antonio** Dgn. (48 c) is one of the southernmost species, from Tucuman, and already rather small. Forewing lead-coloured grey, with dark veins, a dark shade at the cell-end, and a whitish submarginal undulate line. Hindwing hyaline white, abdomen hemochrome.
- rhodator.* **A. rhodator** Hmps. (47 e), from the Bolivian district neighbouring to Tucuman, is very much like *antonio*, somewhat larger, the cell-end spot of the forewing is not so much shaded, the submarginal, small white lunae are more pointed.
- cymothoë.* **A. cymothoë** Drc. (48 a). Wings hyaline, the forewing at the costa and proximal margin whitish speckled with dark brown, the head red and white, thorax brown and white, the abdomen above hemochrome with a black centre. Colombia and Bolivia.
- fulvizonata.* **A. fulvizonata** Hmps. (48 d) is on the wings almost exactly like *cymothoë*, but the thorax is almost entirely white, in front marked red and brown, and the dorsum of the abdomen is quite vermilion without a black centre. Colombia to Peru.
- minerva.* **A. minerva** Dgn. (47 f) has the body exactly like in *cymothoë*, i. e. the abdomen is red with a black dorsal centre, but on the forewing the costal and proximal-marginal spots represent the beginnings and ends of brown bands traversing the whole forewing. Colombia to Bolivia.
- watkinsi.* **A. watkinsi** Rothsch. (48 e) is somewhat larger than *minerva* and *cymothoë*, the forewing traversed by dark bands, with a white basal area and a broad white median band. Abdomen yolk-coloured, laterally spotted black. Peru.
- steinbachi.* **A. steinbachi** Rothsch. (48 e) is the most beautiful and variegated species; forewing crossed by brown and white transverse lines and bands, as well as by chains of yellow spots and crescents. Thorax white, finely marked purple brown, abdominal dorsum haired hemochrome. From Tucuman (Argentina).
- polystrigata.* **A. polystrigata** Dgn. (47 e) has quite the shape of the wings of *Hemihyalea* to which it is probably more closely allied than to most of the *Amastus*. Forewing bone-coloured, recognizable by the numerous white and dark brown transverse striae. Abdomen yolk-coloured. Guiana, Venezuela and Peru; the figured specimen from the Upper Rio Negro.
- aurantiacus.* **A. aurantiacus** Rothsch. (48 d). Like the preceding with numerous bone-coloured and dark brown transverse striae on the forewing, but the ground-colour of the body and wings is a fiery purple pink, in some places tinted yellow. Tegulae and patagia with black dots. From the Chanchamayo in Peru. It was described as *Opharus*; nor is it probably a genuine *Amastus*.
- drucei.* **A. drucei** Rothsch. (48 e) resembles *rufescens* (48 a), but the submarginal line is more finely undulate, and the ♂ hindwing only at the margin tinged red, otherwise hyaline. Abdomen scarlet. Peru.

A. dognini Rothsch. (48 e) is almost exactly like the preceding, the subterminal line is somewhat *dognini*. more irregularly undulate, and there are traces of a light median band; hindwing almost to the margin hyaline. Like the preceding from San Domingo in Peru.

A. cinnamomea Rothsch. (48 e). This species also originates from Peru and chiefly only differs from *cinnamomea*. *drucei* by the bright cinnamon-red colouring of the forewing and the brown, not hemochrome abdominal dorsum. The subterminal line of the forewing is proximally shaded with dark.

A. nigrescens Rothsch. (47 f as *subterminalis*). Body and forewing deep dark brown, so that the darker *nigrescens*. cell-end spot is hardly prominent; an antemarginal row of small light crescents. Hindwing diaphanous red-brown. Peru.

A. pseuderebella Rothsch. Forewing diaphanous blackish-brown, hindwing hyaline, body blackish- *pseuderebella*. brown, only round the base of the abdomen some reddish hair, which may, however, vary in the different specimens. Colombia. — DOGNIN described an insect as **subterminata** which we figure (47 g), and which is *subterminata*. labelled by DOGNIN's own hand as „subterminata“; it differs from *pseuderebella* Rothsch. (= *erebella* Hmps. p. p.) so little that it is hardly noticeable in the figure. But on holding it towards the light, we notice traces of an undulate subterminal line, which disappear in bright light, and the reddish hairing at the base of the abdomen is so well hidden beneath the dark hair that it is only well noticeable on being looked at laterally. By reason of this specimen (in the collection of A. H. FASSL) being labelled „Mt. Tolima, 3200 m“, *subterminata* is hardly more than a race allied to the type.

A. deinella Hmps. (48 d) is quite similarly coloured to the preceding and of the same size, but the *deinella*. head and metathoracal border are orange, and the hindwing is more densely scaled and tinted reddish. Peru.

A. tristis Rothsch. (48 f) is very similar to *deinella*, but much smaller, the forewing towards the margin *tristis*. more intensely darkened, the abdomen at the base yellowish-red, behind yolk-coloured. Colombia, Peru.

A. palmeri Rothsch. (48 f). Wings like in *tristis*, but the whole abdomen from the base to the apex *palmeri*. of a bright orange colour. West Colombia.

A. ferreobrunnea Rothsch. (48 f). Forewing hyaline, only the margins and apical part are dark brown, *ferreobrunnea*. the hindwing hyaline, tinged with yellow. Body yellowish-brown with a white apex of the abdomen. Larger than the two preceding. From Mt. Tolima in Colombia.

A. scriblita Dgn. (47 g). Wings and body bright reddish yellowish-brown, the forewing less diaphanous *scriblita*. than the hindwing. Forewing with a more intensely and darker scaled stripe of the proximal margin. Body densely haired reddish yellowish-brown, in the posterior third the segments are slightly bordered with dark. The ♀ is somewhat paler coloured than the ♂. From the Quindiu Pass, Colombia.

A. tumbilla Dgn. (47 f), being unknown to me in nature, is a small species with a very thick, squat *tumbilla*. body and antennae which, according to the figure, are almost as long as the costa of the forewing. Colour yellowish-brown, without the reddish tinge of the preceding species, the forewing proximally, the hindwing as far as the margin hyaline. From Loja in Ecuador.

A. rubridorsata Dgn. (48 g) strikingly recalls some *Hemihyalea*; the wings are throughout hyaline, only *rubridorsata*. the costa and proximal margin of the forewing and the apical part of the margin of the hindwing are feebly tinted ochreous-white. Head, prothorax, and patagia creamy-white, tinted ochreous; collar, sides of the thorax, centre of the thoracal dorsum, metathorax and dorsum of abdomen except the creamy white apex purple red. Antennae long, yellowish-red. Colombia and Peru.

A. diaphenes Dyar. The type of this Colombian species, being unknown to me, is in the National *diaphenes*. Museum in Washington. According to the figure, it only differs from the preceding by the veins being somewhat marked red-brown, and the abdominal dorsum being red warming into yellow, as well as by the dark orange thorax.

A. childi Rothsch. (♀ = *lehmanni* Rothsch. *) (48 f). Body yellowish-grey, the prothorax and apex *childi*. of abdomen tinted ochreous. Forewing diaphanous red-brown, with a light antemarginal stripe; hindwing yellowish hyaline, the costal margin tinted red-brown. Colombia.

A. rothschildi Dgn. (48 f) is quite similar to *childi*, larger, different by the likewise red-brown body *rothschildi*. with a white face and a lighter abdominal apex, and by the hindwing being brightly tinged red-brown. Colombia.

A. erebelloides Rothsch. (48 d). Thorax and forewing darker, chestnut-brown, otherwise similar to *erebelloides*. the preceding, though larger, except the head also the collar is yellow, the basal half of the abdomen is above purple red, the posterior half blackish. Peru.

*) *Amastus childi* = *Hemihyalea lehmanni* Rothsch. Nov. Zool. 23, p. 269 nec *Elysia lehmanni* Rothsch. Nov. Zool. 17, p. 46.

- muscosa*. **A. muscosa** Rothsch. (48 g). Dark brown, also sepia-coloured, the forewing finely watered with a darker colour, before the marginal area darker than in the marginal area and basal half. Hindwing hyaline, faintly tinged yellowish. Body uni-coloured dark brown. Peru.
- edaphus*. **A. edaphus** Dyar resembles *muscosa*, but it is larger (80 mm). Head, thorax above and the forewing sepia-brown, but the marginal area darker. Abdomen and hindwing yellow, the latter with a sepia-brown costal and apical part. Mexico, discovered by ROBERTO MÜLLER in Tehuacan.
- postflavida*. **A. postflavida** Rothsch. Wings almost entirely coloured as in the two preceding, but the abdominal dorsum behind sulphur-coloured, the 4 last rings edged with black and partly with a blackish partition-line in the centre, like in certain *Opharus*. From Mt. Tolima, discovered by FASSL. Colombia.
- lehmanni*. **A. lehmanni** Rothsch. (48 g). Head and body blackish-brown, forewing dark chestnut-brown, towards the margin darker. Hindwing whitish. Colombia.
- baucis*. **A. baucis** Dalm. (= *bombycina* Perty) is slightly larger than the following species; head and thorax purple red; antennae and spots on the tegulae black, patagia black with a white, anteriorly angular stripe. Abdomen black with some purple at the base and a purple anal part and an anteriorly white sublateral stripe. Forewing blackish-brown with a white subcostal stripe extending to the centre, where it is narrowed, whilst on the under surface of the wing this stripe is set off by purple. Fringes with white tips. Hindwing uni-coloured blackish-brown. Cuba, Para and Bolivia.
- adela*. **A. adela** Schs. (47 g). Head above orange, body black, thorax marked orange and purple, abdomen with a hemochrome, black-marked end. Before the distal margin of both wings a band extends, composed of oval, bone-white spots; by similar spots also the proximal part of the forewing is intermixed, but the forewing is partly yellow. From Castro in the Brazilian State of Paraná.

92. Genus: **Anaxita** Wkr.

With this genus we conclude the very polytypical group of the *Phegopterinae* although it was hitherto reckoned among the „Hypsids“ to which, in fact, it forms a transition. It not only approximates the following group of the *Pericopinae* (the *Hypsinae* of America), by the course of the veins on the hindwing, but there are such remarkable parallels to the South Asiatic *Hypsinae*, that we cannot think of mere convergencies. In the distal halves of the wings, particularly of the forewings, there occurs such a strange form of radiary rays as we find it almost nowhere in the whole lepidopteral range offering such an enormous variety of markings. This is exhibited in *Anax. decorata*, *constricta*, *drucei*, whilst nearly all the other *Anaxita* show at least traces of it. The only corresponding character we find far off in South Asia, in the genera closely allied to the genus *Hypsa*: *Anagnia*, *Aganopsis*, *Euplocia* (Vol. X, t. 27), particularly in the ♀ of *Aganopsis orbicularis* Wkr. (Vol. X, t. 27 a), less distinctly also in several of its allies. And here we must consider that the forms of the two groups have about the same biological position in their different faunae. In both groups we notice, moreover, a certain uniformity of the structure of the body. The peculiarly cylindrical, long ♀ abdomen being stout as far as the end, and exhibiting in the frequently glaring ground-colour a rather genuine Arctoid dorsal marking in the shape of small black spots or stripes, is likewise common to both, as well as the exterior shape of the palpi projecting beyond the head in front like two parallel, long awls.

Of these *Anaxita* about a dozen of forms are known to-day, nearly all of which seem to inhabit the alpine districts and are distributed from Mexico to the south as far as Peru and Bolivia. They presumably only fly in day-time on being chased up, though Mr. GEORG BRUECKNER from Guatemala reports them to be distinctly inclined to forming colonies*). The larvae of the Guatemala-form were found by BRUECKNER in a very bare and rocky Alpine region, at an altitude of 10 600 ft., on a mountain-herb with small leaves, called „Motoze“. The larvae look very much like our *Arctia*-species, but the hairing is not so long as for instance in the larvae of *A. caja*. BRUECKNER found these larvae in a very rugged district, the soil being frozen and covered with ice. He states the colour of these larvae to be olive-brownish, a mixture of yellow and dark hair. The adult larva is 5 cm long, with a bright red ventrum and silvery white stigmata; the ventral feet have outside a black, lustrous spot. On being disturbed, they do not roll themselves up as most of the larvae of the *Arctiinae* do; they therefore behave like the larvae of the hitherto known *Hypsinae* (such as *Aganopsis orbicularis*, *Asota*) and *Pericopinae* (*Pericopis sacrificia*, *Dysschema tiresias*) which neither roll themselves up. Many larvae often proved to have been tampered with. The pupa rests in a very careless web; it is black, 18 mm long, looks as if polished, and, after 40 days, it yielded the imago which is very rarely met with in the open air (BRUECKNER).

*) A strange coincidence is that the palearctic Arctiid *Axiopoena maura* (Vol. II, t. 17 g), which has a remarkable resemblance to some *Anaxita* (*suprema*) in the shape and colouring, exhibits the same peculiar gregarious instinct about which we have referred in Vol. II, p. 97.

A. sophia Dgn. (60 b). This species, according to its author, rather closely approximates the similarly *sophia*. coloured *Phegopterinae* (*Halisidota dukinfieldia* and *nero*, t. 59 f), and like them it forms a transition to the genus *Calidota* in which there are quite similar imagines (such as *Cal. rubrosignata*, t. 56 b), so that these lepidoptera may be better placed hereto. *A. sophia* is jet-black with a hemochrome abdomen and red costal-marginal markings on the forewing.

A. suprema Wkr. (60 a) is likewise black, in this specimen not the abdomen, but the hindwing is red. *suprema*. In the forewing there are fine crimson longitudinal rays of a length up to 1 cm. From the Colombian Andes, at a great altitude, reported from Bogotá; rare.

A. lysandra Drc. which is not lying before me seems to be very similar to **vetusta** Strd. (60 a) which *lysandra*. *vetusta*. may be a form of it, from which the typical *lysandra*, according to the description, chiefly differs by the abdomen being black above. — **martha** Dogn., being likewise unknown to me and perhaps a distinct species, has the *martha*. ground-colour of the hindwing above black, finely strewn with yellow, but in the scheme of markings it seems to agree with *lysandra* and occurs in Peru (Huancabamba) like *lysandra* and *vetusta*.

A. constricta Strd. (60 a). The yellow spots on the forewing mentioned in the preceding species are *constricta*. very much enlarged and increased, and the large yellow thoracal spots surrounded with jet-black and pupilled dark red. The transverse bands of the forewing are connected like an H by an intermediary line, and are much more distinctly prominent than in *vetusta*. Bolivia.

A. drucei (60 b) is a species occurring from Mexico to Guatemala (there in a slightly different form). *drucei*. Here the yellow has entirely disappeared from the forewing, but the grey colour is increased; the hindwing is quite black, the median transverse band is pierced in the submedian area. — In the Guatemala-form, which I denominate **brueckneri** *form. nov.* in honour of its discoverer, the median transverse band is not pierced in *brueckneri*. the submedian area, but it extends uninterruptedly from the costal margin to the proximal margin, and besides it coheres yet on the median branch with the antemedian transverse band. — As to the larva we refer to the characterization of the genus. The imago is rare.

A. sannionis Btlr. (60 b) forms about the intermediary between *constricta* and *drucei*. The transverse *sannionis*. bands are complete and broadly coherent on the median; the distal longitudinal rays are greyish-blue, traversed by red; the hindwing is black. This species is described from Peru.

A. decorata Wkr. (60 a). Forewing of a bright yellow and red colour, the transverse bands complete, *decorata*. but not coherent. Hindwing yellow, in the proximal part and on the abdomen tinged with red; in the marginal part there are often black longitudinal rays which, however, may differ in the single specimens. Mexico, mostly rare.

A. tricoloriceps Strd. is allied to *decorata*, but the longitudinal rays in the forewing are broader, the *tricolori-* *iceps*. hindwing is uni-coloured blackish-brown and thereby easily discernible from the preceding. Likewise from Mexico.

VII. Pericopinae.

We have already mentioned on p. 231 the relation of the *Pericopinae* to the *Arctiidae* and the reasons why we ranged them among the great family of the *Arctiidae*, as has been done in KIRBY's Catalogue. The genus *Anaxita*, which was formerly placed to the *Pericopinae* and now to the *Phegopterinae*, may be regarded as a connecting line between both. According to the characterization of the *Pericopinae* (vid. p. 425), they are composed of somewhat more than 300 well-known lepidopteral forms which on the whole are rather of a homogeneous structure. The few more distinctly varying species (such as *Cyanohypsa stefanelli* Giac., 61 a) are still too little examined and are also very doubtfully placed.

Their range is rather confined, as is mentioned in the description of the groups (p. 425), but they are rather equably distributed in the hot neotropical region. In the lowlands we may reckon at most of the places to meet with about 1 to 1½ dozen species. They generally prefer the wooded districts, but in the real density of the primeval forests almost only smaller species are found; the *Pericopis*, *Eucyane*, *Daritis*, *Phaloë*, and *Calodesma*, being the more beautiful and stronger species are chiefly met with in open spaces, on broad roads, the skirts and clearings of the forests; some species (e. g. *Peric. sacrificia*) even inhabit the waste land, or the slopes that are covered with low bushes. At the greatest altitudes of several thousands of metres the *Anaxita* occur, which were considered as the alpine representatives of the group, before they were taken out from it.

On the whole, the *Pericopinae* are mostly variegated insects of a considerable size. Some ♀♀ have an expanse of more than 10 cm, the average expanse being about 5 to 6 cm. On the wings which are always entirely margined, broad and rather hard, without appendages, tails, indentations, and in the genuine *Pericopinae*

also invariably without any hair-pencils, scent-organs or vesicular swellings, we mostly notice intense colours in plain markings of bands or spots. They are without any protective colours adapting them to the background, but they frequently exhibit large transparent or also quite hyaline areas. Their motley appearance, which is mostly not confined to the wings, but also comprises the abdomen which is often vermilion or orange, with light spots or white bands, is another proof of their belonging to the Arctiids, in as much as it can mostly only be regarded as a premonitory shield, not as a mimetic or other secondary mark.

The marking is mostly also like in the Arctiids. Forewing of a dark ground-colour, with spots or bands of glaring colours, hindwing red or yellow with a dark marginal band. In the marking there are most peculiar parallels, particularly the remarkable consistency of large and small forms that are little allied to each other. Thus, for instance, *Ephestria melaxantha* (61 b) which is common near Rio de Janeiro looks exactly like the gigantic image of *Cyllopoda dichroa* being very common at the same place; *Eucyane bicolora* (61 c) which, near Santos in South Brazil, sometimes flies in day-time round the ramified branches of the trees at the skirts of the forests, is the entire image of an enlarged *Phaloësia syma* (65 e); *Eucyane celadon* (61 d) seems to be a very large *Phal. rica* (65 f); in *Euc. aletta* (61 e) the colouring of the smaller *Calodesmia melanchroia* (61 a) is repeated, and so on.

The marking of the individual species is generally not very constant in the *Pericopinae*. In dealing with the badly or little flying butterflies of the neotropical region (*Erycinidae*, *Ithomiinae*) we pointed out (Vol. V, p. 116 and 619) that the specimens of a certain geographical point are mostly consistent even in the minutest details of the colouring and marking, but that already an adjoining habitat, being often but few days' marches distant, shows small, though just as constant variations of its inhabitants, so that we might speak of subordinate races. This is not the case with the *Pericopinae* which, being very migratory, are never isolated in such colonies. Their occurrence in their patriae is by no means so local, the distribution of their species neither so dependent upon special larval food nor upon the landscapes, as we have noticed with the *Erycinidae* where sometimes a habitat of but few hundreds of square metres is inhabited by numerous specimens of a species which is nowhere to be met with for many miles round. Thus the individual variability of the *Pericopinae* is very much greater; specimens, having been captured at the same hour and on the same lantern, may differ considerably in the width of the bands and the distinctness of the spots, and they may, on the other hand, agree with such from remote districts. This seems to have become known to most of the describers of forms of *Pericopinae*, for the synonymy does by far not exhibit the abundancy of dispensable names as for instance in the *Erycinidae* where some species have a dozen or more denominations.

In the genuine Arctiids we have not been able to discover a distinct mimicry in their exterior, whilst in the *Pericopinae* it is met with in several cases. The colouring of most of the species in spite of its striking character is entirely singular. We do not know any imago repeating, not even in the rough, the colouring of an *Ambryllis boisduvalii* (60 b), a *Daritis thetis* (60 c), *Pericopis sacrificia* (64 c). But in quite a number of species mimicry is unquestionably present; we have therefore often added to the descriptive text the statement of the presumptive model.

Nevertheless most of the *Pericopinae* exhibit an internal protection. On taking a *Dyschema tiresias* by the thorax or wings, it at first keeps quiet, folding its wings backwards together and its legs as if it were dead. Then, however, with a peculiar, bubbling or groaning noise, it intermittently discharges a yellow fluid which covers the head and anterior body of the insect with a dense spume, entirely like the so-called cuckoo-spit of the European frog-hopper (*Ptyela spumaria*). When the danger is over, the spume melts and its remainders are often yet noticeable as reflecting, gelatine-like spots on the wings of the collected specimens. Quite similar observations have been stated by DYAR in *Composia fidelissima*.

On the whole, however, we must just in the *Pericopinae* be on our guard of seeing an effect of mimicry in every resemblance. We have already mentioned above the frequently very exact consistency of the colouring in differently sized *Pericopinae* or with members of other groups (*Cyllopodidae*). But also a striking repetition of the colouring in lepidoptera, living distantly separated is not at all uncommon; so for instance there exists a remarkable consistency between the Brazilian *Pericopis transversa* (63 f) and the western neotropical Agaristid *Parothria ecuadorina* (Vol. VII, t. 1 e) and the Central American *Seirocastnia panamensis* (Vol. VII, t. 1 d); even in palearctic lepidoptera we often meet with a consistency which is of course accidental, as for instance of *Calodesma melanchroia* (61 a) with the South Asiatic *Chalcosia panthona* (Vol. X, t. 3 e) or the Indian *Euproctis leucospila* (Vol. X, t. 44 a). Such accidental phases are, in contradistinction to the biologically established ones, called „Collective mimicry“.

The mostly rather large species of the *Pericopinae* are flying with an accelerated speed, but still somewhat unwieldily. The cylindrical abdomen which is tightly filled with a great number of very small eggs and which

in the ♀♀ of some species may attain an enormous stoutness (e. g. in *Daritis trapeziata*, *Composia credula*, *Eucyane pylotis*, *Dysschema heliconides* and many other species), makes the flight sluggish, rectilinear, and causes it to rest frequently, so that it is not difficult to capture the scared up insect, unless it follows its habit of flying up to the crowns of the trees.

On being scared up all *Pericopinae*, it appears, fly in daytime, but the swarming time of many species is at night. Prof. CARLOS HOFFMANN, in Mexico, whom we herewith heartily thank for the kindness of communicating his numerous biological observations, distinguishes the mimetic species as day-fliers from the non-mimetic species as night-fliers. The latter often come to the lantern, but generally not so often as might be expected from the frequent occurrence in daytime and the commonness of the larvae.

The larvae have two different types: forms densely clothed with bristly hairs not quite dissimilar to the larvae of the Arctiid genus *Ecpantheria*, and such resembling the type of our *Callimorpha*-larvae. For the first form the larva of *Dysschema tiresias* may serve as example, for the latter that of *Pericopis sacrificia*.

The pupae of the Pericopids, as far as my experience goes, are badly preserved. Those of *Dyssch. tiresias* are freely suspended between the leaves of the ends of the bushes in a web made of few, long silk-threads, so that they are sometimes to be noticed already from a great distance as a dark centre in a web, suspended like a spider. This remarkably resembles the habit of Indian Hypsids (such as *Hypsa alciphron*), which lepidopteral group we have denoted to be the Indian representatives of the American *Pericopinae*. In a similar way as there, the pupa of the *Pericopinae* is also quite normally shaped, recalling that of our *Callimorpha*, and like the pupae of many other Arctiids (such as *Oeonistis quadra*) very glossy, as if it were polished.

The pupal stage seems to be rather short (sometimes about a fortnight) in tropical species. The imagines are so very tenacious of life that it is quite impossible to squeeze them to death with one's fingers; they also offer great resistance to the killing-bottle.

Pericopinae.

The members of this subfamily are generally denoted as the American *Hypsiidae*; HAMPSON ranged them with *Callimorpha* among the *Callimorphidae*, which combination we cannot follow here, since *Callimorpha* is better placed to the genuine *Arctiinae* by reason of the neurulation as well as of the larva. The *Pericopinae* differ from all the other Arctiids by the peculiar course of vein 8 in the hindwing. The latter is at the extreme base entirely fused with the anterior edge of the cell in the Arctiids (i. e. its base is situate above the anterior edge of the cell, which looked at from above is no more visible at this place); in the *Pericopinae*, however, the extreme base of vein 8 is separate, the anterior edge of the cell rises behind it. The larva of the *Pericopinae*, on the 2nd and 3rd thoracal segment, has but 1 tubercle above the row of stigmatal tubercles; it thereby differs from the larvae of all the other Arctiids which have at least 2 tubercles there. In primitive *Pericopinae* (*Composia*) there are besides two subdorsal tubercles which, however, are already slightly fused. *Callimorpha* has more than 1 tubercle, whereby it also proves its distant relationship to the *Pericopinae*. The latter invariably show a well developed proboscis whereby they differ from all the similar Lymantriids; the hind tibiae exhibit 2 pairs of spurs in the older genera, in the others 1 pair. The tympanal organ is thoracal, and in its structure resembles that of the *Arctiidae* and *Syntomidae*, thus testifying its close relationship of these three groups. Vein 5 in the forewing rises nearer at 4 than at 6, distinguishing it from the similar Geometrids and Dioptriids. There are here accessory eyes, which are wanting in the *Lithosiinae*. In contrast with similar *Syntomidae*, vein 8 in the forewing is well developed. The subfamily comprises about 310 forms chiefly distributed in Tropical America; few go as far as the northern and southern temperate zones. The veins were denominated in accordance with the system of COMSTOCK-NEEDHAM; thus the subcosta denotes vein 12 in the forewing, 8 in the hindwing; the radial branches 1 to 5 denote the veins 11 to 7 in the forewing, the radial ramus 7 in the hindwing. The median branches 1 to 3 are the veins 6 to 4 in the forewing and hindwing, the cubitus 1 and 2 are the veins 3 and 2, the analis is the fold-vein 1 c, and the axillaris means 1 a and 1 b. Some genera are enumerated by way of appendix, although they are no genuine *Pericopinae*, vein 8 in the hindwing is not separate at its base. But as they are mostly sought for among the *Pericopinae*, they have here been dealt with for the reason of practical purposes. In some genera with a distinct sexual dimorphism (*Pericopis*), future investigations will necessitate yet several species to be combined.

Review of the genera of the *Pericopinae*.

1. In the hindwing the subcosta is separate at the base, after that for some distance fused with the anterior edge of the cell (genuine *Pericopinae*).

A. Hind tibiae with 2 pairs of spurs.

- I. 2nd radial branch in the forewing separate or only partly anastomosing with the 3rd to 5th.

1. In the forewing all the veins are present.
 - a. In the hindwing the 3rd median branch and 1st cubitus are not forked.
 - α. In the hindwing the posterior angle of the cell is hardly produced.
 - *. Margin of the hindwing before the anal angle with a concave indentation. *Ambryllis.*
 - **. Margin of the hindwing everywhere convex. *Daritis.*
 - β. Posterior angle of the cell of the hindwing laciniformly produced.
 - *. 3rd joint of the palpus at least one third as long as the second.
 - o. 1st cubitus in the hindwing in the centre between the 2nd cubitus and 3rd median branch, posterior angle of the cell of the forewing very much produced. *Xenosoma.*
 - oo. 1st cubitus in the hindwing nearer at the 3rd median branch, posterior angle of the cell of the forewing less produced. *Thyrgis.*
 - **. 3rd joint of the palpus one fourth the length of the second at most. *Composia.*
 - b. In the hindwing the 3rd median branch is forked with the 1st cubitus.
 - α. In the forewing the 2nd cubitus is nearing the first, the distance between both being one half at most of the length of the posterior edge of the cell from the base to the 2nd cubitus. *Gnophaela.*
 - β. 2nd cubitus farther towards the base, its distance from the 1st cubitus more than $\frac{1}{2}$ of the basal portion of the posterior edge of the cell. *Pseudophaloë.*
 2. In the forewing one vein (the 3rd radial) is absent. *Josiomorpha.*
- II. In the forewing the 2nd to 5th radials are forked.
1. 5th radial rising before the 2nd.
 - a. In the hindwing the 2nd median branch is about in the centre between the 1st and 3rd median branches. *Cyanohypsa.*
 - b. 2nd median branch nearing the 3rd.
 - α. 1st radial in the forewing before the middle of the distance of the 1st and 2nd cubitus.
 - *. 1st and 2nd cubitus in the forewing converging towards the margin. *Ephestris.*
 - **. 1st and 2nd cubitus diverging at their rise. *Isostola.*
 - β. 1st radial in or behind the middle of the distance of the 1st and 2nd cubitus *Calodesma.*
 2. 2nd radial rising before the 5th.
 - a. The 3rd joint of the palpus far less than a half of the second. *Eucyane.*
 - b. The third joint of the palpus at least a third of the second.
 - α. Third palpal joint little shorter than the second. *Josiomorphoides.*
 - β. Third palpal joint a half of the second at most. *Sagaropsis.*
- B. Hind tibiae with 1 pair of spurs.
- I. In the forewing the 2nd radial is separate, or only anastomosing with the 3rd to 5th radials.
 1. In the forewing the 5th radial branch rises before the 3rd.
 - a. In the hindwing the 3rd median branch is not forked with the 1st cubitus.
 - α. Pinnae of the ♀ antennae shorter than the diameter of the shaft (the 2nd radial often anastomosing with the 3rd to 5th. *Pericopis.*
 - β. Pinnae of the ♀ antennae at least as long as the diameter of the shaft.
 - *. 3rd palpal joint very much shorter than the second. *Dysschema.*
 - **. 3rd palpal joint about half the length of the second.
 - o. Distance of the 1st radial from the 2nd in the forewing twice as long as that from the 2nd to 5th radials. *Are.*
 - oo. Distance of the 1st radial from the 2nd about the same as that from the 2nd to 5th radials, or shorter. *Phaloë.*
 - b. In the hindwing the 3rd median branch is forked with the 1st cubitus. *Ctenuchidia.*
 2. In the forewing the 3rd radial branch rises before the 5th. *Phaloësia.*
 - II. In the forewing the 2nd to 5th radials are forked.
 1. In the hindwing the 3rd median branch is not forked with the 1st cubitus.
 - a. In the forewing the 2nd to 5th radials before the cell-angle, separated from the 1st median branch, in the hindwing the distance from the 3rd median branch to the 1st cubitus is less than twice as long as the distance from the 2nd median branch to the 3rd. *Hyalurga.*

- b. In the forewing the fork of the radials 2 to 5 from the cell-angle, with the 1st median branch from the same place or forked; in the hindwing the distance of the 3rd median branch to the 1st cubitus is at least twice the distance from the 2nd median branch to the 3rd.
- α. Posterior angle of the cell in the forewing projecting. *Scearcia*.
- β. Posterior angle scarcely projecting. *Stenognatha*.
2. In the hindwing the 3rd median branch and the 1st cubitus are forked. *Graphelysia*.
2. In the hindwing the subcostal is also at the extreme base fused with the anterior edge of the cell (not genuine *Pericopinae*).
- A. Accessory eyes wanting, 1st radial in the forewing anastomosing with the subcosta (*Lithosiina*). *Gardinia*.
- B. Accessory eyes present, 1st radial always quite separate (*Micrarctiinae*).
- I. In the forewing the 2nd and 5th radials rise almost from the same place. *Episcea*.
- II. The 5th radial rises considerably before the 2nd. *Crocomela*.

1. Genus: **Ambryllis** Wkr.

This genus, in the habitus, still strongly recalls the genuine Arctiids. Hind tibiae with 2 pairs of spurs. In the forewing the 2nd radial is not forked with the 3rd to 5th, mostly connected with it by a transverse vein or anastomose. 3rd to 5th radial branch forked, the 5th rising before the 3rd, 1st median branch rising separate from the fork of the 3rd to 5th radials. In the hindwing the radial ramus and the 1st median branch rise from the same place, and so do the 3rd median branch and 1st cubitus; posterior ends of the cell not laciniformly produced. The margin exhibits a concave indentation before the anal angle. Hitherto only 1 species is known.

A. boisduvalii Hoev. (= funeralis H.-Schäff.) (60 b). Head and thorax black, ground of the patagia whitish-yellow, collar above white. Abdomen white, laterally with two rows of black spots, the last segment black, with an ochreous anal tuft. Wings transparent white, on the forewing the costal margin and anal margin are somewhat more densely dusted, with four black, generally red-pupilled spots. On the axillaris usually a black longitudinal stripe which, however, may also be absent. Hindwing only with some small, sometimes absent, red marginal spots. Beneath as above, the red fillings of the black spots on the forewing more distinct, particularly in the spot in the cell. Extreme base on all the wings with an orange spot. In South America from Venezuela to South Brazil. *boisduvalii*.

2. Genus: **Daritis** Wkr.

Entirely the same as the preceding genus except that here the indentation of the margin at the anal angle of the hindwing is absent. In the species of the genus approximating the preceding there is a considerable sexual dimorphism noticeable.

D. centenaria Burm. (60 d) resembles *A. boisduvalii* Hoev. in the marking of the wings, but all the markings are enlarged, the proximal margin of the forewing is broad black. The hindwing has a narrow black margin with continuous red spots. Under surface likewise with more pronounced red markings, the costal margin of the forewing black, filled up with red. Abdomen white, middle line of the dorsum and of the ventrum black, one black lateral line, ground of patagia white, otherwise like the preceding species. Argentina (Zarate); Uruguay (Montevideo). *centenaria*.

D. trapeziata Wkr. (= rubripicta Btlr., woodii Btlr.) (60 c). The ♂ resembles yet the preceding species, but the black markings in the forewing are still more extensive; in the hindwing the black margin is broader, with bluish-white dusted spots, the red likewise broader, on the transverse vein a red, black-edged spot. Collar and base of patagia brimstone-coloured, the black markings of the abdomen more extensive. ♀ with a brownish-black ground-colour on all the wings; forewing partly strewn with red scales, the markings brimstone-coloured, dusted somewhat blackish. Hindwing with whitish marginal dots, a red submarginal band being narrow in front and broad behind, a brimstone-coloured spot in and behind the cell. Beneath the red is more extensive. Abdomen black with above broad, beneath narrow yellow segmental margins, the collar and base of patagia being yellow. Distributed from Venezuela to Brazil. *trapeziata*.

D. thetis Klug (= mariamne Geyer) (60 c). Both sexes more similar, in the ♂ the inner area of the hindwing is hyaline transparent, in the ♀ the whole hindwing is of an ochreous-yellow ground-colour. Patagia in front yellow, abdomen red with a black dorsal line and yellow ventral side. — In the form **fenestrata** Btlr. in the ♂ and ♀ four fifths of the cell of the forewing are hyaline, in it there is an oblong spot of the ground-colour, the white markings are broader. — The form **howardi** Edw. has in the ♂ the reddish-yellow colour of the margin of the hindwing for the greatest part replaced by black. — Larva irregularly banded black and ochreous-yellow, the ground-colour being dusky ochreous, a broken black dorsal stripe and irregular subdorsal and subventral dots. Segments 5, 6, 9, 11 and 13 feebly banded black. Mexico to Costa Rica. *thetis*, *fenestrata*, *howardi*.

jaonis.

D. jaonis *Strd.* (60 g) resembles the ♂ of *trapeziata* *Wkr.* (60 c), in the forewing the discoidal spot on the transverse vein and the spot situate basally to it are connected; the latter as well as that situate at the tornus being broadly filled with red; the margin of the hindwing is in a basal direction from the red band much broader black, as well as the streak on the cell-end. Brazil (S. João).

3. Genus: **Thyrgis** *Wkr.*

From the preceding genera *Thyrgis* is distinguished by the posterior angle of the hindwing projecting distally. The antennae are in the ♂ bipectinnate, in the ♀ doubly dentate, the pinnae not attaining the thickness of the shaft. In the forewing the 1st and 2nd radials are separate, the 3rd to 5th being forked, the 5th rising before the 3rd; the 1st median branch is separated from this fork. In the hindwing the radial ramus and the 1st median branch rise on a short fork. The 3rd palpal joint attains about half the length of the second. From similarly coloured and marked species of *Calodesma*, *Thyrgis* is distinguished by the separate course of the 2nd radial in the forewing; in similar *Syntomidae* (*Coreura*) the hindwing lacks the subcostal. Hereto probably also *Cal. kedar* and *dilutana* *Drc.* belong (p. 432).

militta.

Th. militta *Stoll* (60 e). ♂ and ♀ not differently coloured. The tinge of the forewing varies from crimson to orange and yellow. Hindwing either uni-coloured or with traces of a yellow or red submarginal band. The typical *militta* *Stoll* with a narrower band of the forewing in Brazil, Bolivia, Venezuela, Colombia.

phlegon.

— **phlegon** *Drc.*, from Ecuador, the Upper Amazon River and East Peru, with a band of the forewing of about 4 mm width.

marginata.

Th. marginata *Btlr.* (60 e) differs from the preceding species by the more distal position of the red transverse band of the forewing; in *militta* about a sixth, in *marginata* only a tenth of the discoidal cell is red. The 3rd palpal joint is more than half the length of the 2nd. Hindwing with a light red marginal band of about 4 mm width. I did not see any forms of this species with yellow bands. Nicaragua, Bolivia.

constrictifascia.

Th. constrictifascia *Dogn.* was not before me. It is said to resemble *militta phlegon*, the red band is said to be straighter and not to traverse the discal cell, but only to touch it. It may be an *Eucyane*. Ecuador.

angustifascia.

Th. angustifascia *sp. n.* resembles *marginata* and was captured together with it. The position of the band of the forewing is like in the preceding, the band is narrower, proximally and distally with more pronounced projections, much narrower towards the anal margin, terminating behind or before the axillaris. The red margin of the hindwing is darker red, 2 mm broad at most. 1 ♂ from Bolivia (Bueyes, type), and 1 ♀ from Colombia in the Zool. Museum at Berlin, another ♀ from Ecuador in the Tring Museum.

chislon.

Th. chislon *Drc.* was not before me. Similar to *childon*, but the band of the forewing is much narrower, whereby it resembles the yellow-banded specimens of *militta* from which it differs beneath by the yellow abdomen and the blue submarginal dots of the forewing. Ecuador.

childon.
columbiana.

Th. childon. Head and collar with white dots. Ventral part of the abdomen yellow, other parts of the body bluish-black. Wings blackish-brown, proximally with a blue reflection, forewing with a broad yellow transverse band. Under surface of both wings with a row of whitish-blue submarginal spots. **childon** *Drc.* with a narrower yellow band the edges of which are almost parallel. Ecuador. — **columbiana** *subsp. nov.* is somewhat larger, the yellow band is broader, distally convex. Colombia.

flavonigra.

Th. flavonigra *Dgn.* is unknown to me, and I can therefore not decide whether it is a genuine *Thyrgis*. Forewing black with a yellow transverse band not reaching the costa and proximal margin. Hindwing uni-coloured black. Body black with yellow lateral spots at the collar. South East Peru (Rio Huacamayo).

ceron.

Th. ceron *Drc.* is likewise unknown to me; underside of the head yellow, the body black. Wings black, the forewing with a yellow discal band as in *militta*, hindwing with a yellow-margined apex. Colombia and East Peru.

4. Genus: **Composia** *Hbn.*

Distinguished from *Thyrgis* by the 3rd palpal joint being very short, one fourth the length of the 2nd at most.

credula.

C. credula *F.* (= *sybaris* *Cr.*) (60 e). Body and wings blackish-brown, all over covered with spots. Ventral side of the abdomen white with black segmental margins. At the costa of the forewing in the basal part above 2 or 3 red spots, beneath a red stripe. Antilles (Jamaica, Haiti, Portorico, St. Thomé).

fidelissima.

C. fidelissima *H.-Schäff.* (= *olympia* *Btlr.*) (60 e) resembles the preceding, but it is less spotted white. Hindwing only with submarginal spots, intensely suffused with blue. Abdomen above uni-coloured black, lustrous blue, below like in the preceding species. Common in Cuba, but also from Florida to Brazil. — Larva

shaped more like in the Noctuids, the thoracal subdorsal tubercles are not yet fused, but are inclined to it. First stage dull orange, the segments 5 and 6 and 9 to 11 reddish purple, tubercles dark; adult larva of a glaring pinkish-red colour with a violettish-blue reflection, scantily haired. Stigmata pale orange. On the segments 2 to 5 the lowest two, on 5, 6 and 9 to 11 all the tubercles are blue. Pupa fastened with very few threads on the head and cremaster, reddish mahagoni-coloured, with blue and violet spots on the wing-cases. Foodplant: *Echites umbellata* and *Canavalia obtusa*. — As to the peculiar behaviour of the imago on being taken, discharging a yellow spume with a bubbling noise, cf. the introduction (p. 424).

5. Genus: **Xenosoma** Fldr.

In the habitus the genus resembles *Coborisa*; it was hitherto referred to the Lymantriids from which it differs by the well developed proboscis, but it has 2 pairs of spurs on the hind tibiae. In the structure similar to *Thyrgis*, but the 1st cubitus in the hindwing about in the centre between the 2nd cubitus and 3rd median branch, and the cell of the forewing is behind more produced. Antennae in the ♂ strongly pinnate, the pinnae towards the apex, however, more abruptly shortened than in *Thyrgis*. 3rd palpal joint just as long as the 2nd.

X. progonum *sp. n.* (60 d). Head and thorax varying from wood-colour to an ochreous yellowish, *progonum*. palpi darker. Abdomen white, anal tuft ochreous. Wings hyaline milky white, the distal margins with a blackish-grey, posteriorly narrowed border. Veins greyish-brown, behind the cell a blackish spot at the proximal margin. Costa and proximal margin of forewing more intensely dusted greyish-white. Beneath as above. Peru. ♂ type from La Oroya, Rio Inambari (3100 feet) in the Tring Museum, ♀ type from Bolivia in the Berlin Museum.

X. nigromarginatum *Drc.* is very much like *progonum*, the patagia white with a yellow basal spot, *nigromarginatum*. the black border on the 1st median branch in the forewing only $1\frac{1}{2}$ mm, in the hindwing 1 mm; in the ♀ of *progonum* as much as 4 (in the ♂ 2) resp. 2 mm broad. Costa Rica.

X. flavisedes *Dogn.* (60 d). Body whitish, head, collar, thorax below, patagia and 2nd palpal joint *flavisedes*. and anal tuft ochreous yellow, 3rd palpal joint black. Wings quite whitish hyaline, at the margins, particularly before the apex of the forewing, more densely dusted with a somewhat greyish colour. Venezuela.

X. flaviceps *Wkr.* (= *nigricosta* Fldr.) (60 d). Body as in *flavisedes*. Wings quite milky white hyaline, *flaviceps*. nor are the veins darker; costa of forewing narrowly black. Mexico to Venezuela.

H. giganteum *Drc.* with whitish hyaline forewings exhibiting a yellowish base and proximal margin, the abdomen beneath pale yellow, with an expanse of 65 mm, from Honduras, is probably a Lymantriid.

Volcan de Chiriqui, Vol. 1, p. 543.

6. Genus: **Pseudophaloë** *gen. nov.*

Hind tibiae with 2 pairs of spurs (in *Phaloë* Guér. only 1 pair). In the forewing the 1st and 2nd radials are separate, the 3rd to 5th forked, the 5th before the 3rd; the 1st median branch from the same place as the fork. 2nd cubitus rising far before the 1st, the first portion of the posterior edge of the cell less than twice the length of the second. In the hindwing the radial ramus and the 1st median branch, as well as the 3rd median branch and the 1st cubitus are forked. Length of ♀ antennal pinnae not quite attaining the thickness of the shaft. Type of the genus: *Ps. verania* *Drc.*

Ps. verania *Drc.* Body blackish-brown, head and collar with white dots, the margins of the abdominal *verania*. segments narrow white, sides and last segment of abdomen are red. Wings blackish-brown, forewing with a red basal spot, a yellow median band, and a yellow subapical spot, hindwing with lighter yellow spots at the costa, behind the subcostal, behind the bifurcation of the radial ramus and 1st median, and between the 2nd median and 1st cubitus. Beneath as above the veins at the base whitish; in the hindwing the spot behind the subcostal is towards the base extended to a stripe, a stripe below the anterior edge of the cell and 2 or 3 bluish-white longitudinal stripes at the anal angle; distally to the latter 1 or 2 yellow spots. Mexico, Honduras, Guatemala.

Ps. schausi *Edw.* is unknown to me in nature. It differs from the preceding by exhibiting beside *schausi*. the subapical spot of the forewing another spot in its prolongation at the centre of the margin. In the original description the red lateral stripes of the abdomen, which are present in *verania*, are neither mentioned. Mexico.

Ps. helotes *Drc.* is similar to *Ps. verani*, the bands of both wings are brimstone-coloured, the subapical *helotes*. spot of the forewing in the ♀ smaller, only in one cell (in *verania* it extends to the 2nd, here to the 1st median branch). The yellow spots of the hindwing are broader, more closely together, no yellow spots in the anal portion beneath. Panama (Volcan de Chiriqui).

Ps. stenoxantha *sp. n.* is allied to *helotes*, on the abdomen not only the last, but also the two preceding *stenoxantha*. segments are beneath red. The centre of the other segments on the ventral side broader white; the band of the forewing is only half the width of that in *helotes*, the subapical spot in front extending beyond the 5th radial.

The yellow spots of the hindwing are lighter than the band of the forewing, the hindwing beneath shows more abundant light longitudinal stripes. Colombia, Mexico. ♂ type in the Berlin Zool. Museum from Colombia (Antiochia).

- veranioides*. **Ps. veranioides** *sp. n.* (60 d) is similar to *verania*, but smaller, the yellow median band of the forewing only half the width of that in *verania*, the subapical spot smaller. Abdomen laterally only on the 2nd segment with a red spot. ♂ and ♀ from Mexico, Misantla (June 1911).
- troetschi*. **Ps. troetschi** *Drc.* Body as in the preceding species, the last three abdominal segments above and beneath red. Forewing as in *verania*, the yellow band more proximally situate and more slanting. The yellow band of the hindwing is broader and longer, extending to the 1st cubitus. Panama (Volcan de Chiriqui).
- tellina*. **Ps. tellina** *Weym.* (60 d). Body black, beneath and laterally yellow. Collar with a lateral ochreous spot. Forewing blackish-brown, costa basally with an ochreous longitudinal streak. A yellow discal band rather intensely darkened by black dusting and traversed by black veins extends from the costa to the first cubitus, a hyaline yellow subapical spot is parted black by the 5th radial. Hindwing yellow with a broad black margin and costa, from the former a black spot goes across the transverse vein. Fringes blackish-brown, those of the hindwings partly spotted yellow. Beneath as above, the yellow markings more distinct. Brazil: Rio Grande do Sul.
- tessmanni*. **Ps. tessmanni** *sp. n.* is similar to the preceding, the costal streak at the base absent. The discal band of the forewing distinctly hyaline yellow, the subapical spot whitish hyaline, extending across the 2nd median branch hindward. Costa of forewing only in the last third black, the transverse vein not marked black. The light area of the hindwing is quite pale yellow. Beneath as above, white marginal spots at the 2nd cubitus of the forewing, the radial ramus, the 2nd cubitus and axillaris of the hindwing. Head, collar, and patagia with white dots; abdomen white, dorsal line, the last two segments and the posterior edges of the two preceding segments above black. 1 ♀ (type) from the Rio Pachitea, Monte Alegre, East Peru, in the Berlin Zool. Museum, discovered by G. TESSMANN. In the Tring Museum a ♀ from East Bolivia.
- tellinoides*. **Ps. tellinoides** *sp. n.* resembles *tellina* from which it differs by but one red spot at the costa of the forewing above, otherwise all the ochreous markings being red here. The yellow discal band of the forewing is broader, the apical spot shorter (only in 2 cells), more slanting, yellow. In the hindwing the transverse vein is less marked black, the margin projects less at it. Type (♀) from North-West Ecuador (Salidero) in the Tring Museum.
- patula*. **Ps. patula** *Wkr.* resembles *tessmanni*. Abdomen as far as the apex covered with white scales, transverse band of forewing in front narrower, behind the cell suddenly broader, ground-colour of hindwing mostly white, distally growing more hyaline. Bolivia.
- isosoma*. **Ps. isosoma** *Prout* resembles *patula*, with a red streak at the base of the costa on the forewing and a white discal band. Chanchamayo, Peru.]
- triangulata*. **Ps. triangulata** *Dogn.* (60 e). With yellow lateral lines on the abdomen, beneath curled white. All the markings saffron-coloured, forewing with a triangular spot, cutting the cell with the anterior edge behind at $\frac{1}{4}$, in front at $\frac{2}{3}$, its posterior edge being undulate. The second spot between the 3rd and 5th radial; veins black. Hindwing with a band as in *latifascia*, but the veins mostly black. Bolivia, Peru.
- Ps. cotta**. ♂: Body blackish-brown, before each of the antennae one white spot, collar above red. Abdomen above lustrous blue, beneath with white segmental margins. Forewing brown with a red costal streak at the base, a narrow pale hyaline yellow discal band and a similar subapical spot extending from the 1st radial to behind the 3rd median. Hindwing blackish-brown, with a blue lustre, from the base to the centre of the 3rd median branch between the anterior edge of the cell and the axillaris light brimstone-coloured. Beneath as above, costa and anal angle of hindwing with white longitudinal stripes. **cotta** *Drc.* (60 f), from Panama (Chiriqui), has pale yellow markings; — **levisi** *Schs.*, from Nicaragua, has greenish-yellow markings; the ♀ on the forewing only has a greenish-yellow band beyond the cell, being after the tornus narrowed to a dot. The hindwing shows on the blackish-blue ground a narrow bent hyaline band beyond the cell.
- cerealia*. **Ps. cerealia** *Drc.* (60 f). Body black, head with white dots, collar with red lateral spots. Abdomen laterally ochreous-yellow, beneath whitish-yellow, above with a blue reflection, with light segmental margins. Forewing blackish-brown, with a red costal stripe at the base, a triangular yellow spot in the angle between the posterior edge of the cell and the axillaris, a similar discal band between the anterior edge of the cell and the axillaris, and a similar, partly hyaline subapical band between the 5th radial and 1st cubitus. Hindwing yellow with a black, blue-dusted costal margin and distal margin. Panama (Chiriqui) and Colombia.
- ninonia*. **Ps. ninonia** *Drc.* (60 g). In the habitus similar to an *Eucyane*; body blackish-brown, collar red, forewing brown, with a red basal streak at the costa and a hyaline transparent subapical band between the 5th radial and in the tornus behind the cell. Hindwing black, with an intense blue lustre, with a narrower submarginal

hyaline band. Abdomen blue, beneath with white segmental margins. In the type the 1st and 2nd radials are to a great extent fused. Panama (Chiriqui) and Sitio (Costa Rica).

Ps. latifascia *sp. n.* (60 d) resembles *tessmanni*, the light area of the hindwing is just as dark yellow *latifascia*. as the transverse band of the forewing, which is more slanting and broader here. Subapical spot hyaline. Abdomen above darkened, all the light portions of the body chamois, not white as in *tessmanni*. ♂ type from Iquitos (Peru) in the Tring Museum.

7. Genus: **Gnophaela** Wkr.

Chiefly agreeing with *Pseudophaloë*, but the 2nd cubitus on the forewings rises here somewhat more distally than in the preceding genus.

G. latipennis *Bsd.* (= *hopfferi* *G. & R.*) (60 f). Body blackish-brown with a blue lustre. Prothorax *latipennis*. below and collar laterally ochreous-yellow. Abdomen with a white lateral line. Wings blackish-brown, forewing with a discal band of light yellow spots, one of which is quadrangular, in the cell, another in the cell-angle before the 2nd cubitus, one being prolonged towards the base between the 2nd cubitus and the axillaris. A subapical row of 4 spots between the 5th radial and 1st cubital. Hindwing correspondingly marked, discal band composed of only 2 spots, the spot before the 2nd cubitus being absent. Distally to the transverse vein 2 spots. Beneath as above. Pacific States of North America. — Larva of a black ground-colour, tubercles bluish-black, with a broad yellow dorsal stripe, lateral yellow streaks forming a broken line, and a yellow stigmatal band. Ventrums pale yellow, feet black. It lives on *Cynoglossum occidentale*.

G. vermiculata *G. & R.* (60 f) is similar to *latipennis*, but the wings in an oblique light show a blue *vermiculata*. lustre, the markings are lighter, whitish-yellow; on the forewing, the light spot in the cell is slantingly prolonged almost to its ground; the subapical spots are broader. Hindwing quite light, the costa, margin and anal margin as well as the veins are dark. — In *continua* *Edw.* the distal discal spot of the forewing is prolonged, so that *continua*. it touches the subapical spots; thereby arises a light central space into which, behind the transverse vein, a black spot projects. — The form *discreta* *Stretch* (= *arizona* *French*, *morrisoni* *Drc.*) has a light discoidal spot *discreta*. occupying only half the cell, in the hindwing the transverse vein and the 1st cubitus are broadly marked black, so that the subapical spots are separated from the discal spots. — The valves are narrower than in the preceding species. North America, Pacific States and Mexico. — Larva quite similar to that of the preceding.

G. aequinoctialis *Wkr.* (60 g) differs from the two preceding by its narrower forewings. The discal *aequinoctialis*. spot behind the cell is prolonged to the base; the two other discal spots as in *latipennis*. Hindwing like in the form *arizona*, the black of the margin as far as the cell very broadly projecting. Wings with a more intense blue lustre. Lateral dots of abdomen not strigiform as in the preceding species. — The form *disjuncta* *Edw.* *disjuncta*. has in the subapical area of the forewing behind the 1st cubitus another light dot. From Mexico to Colombia and Venezuela.

G. clappiana *Holl.* (60 g) which was not before me, has uni-coloured black hindwings, and in the discal *clappiana*. area of the forewing only a square spot (in the cell); the subapical row only contains 3 spots. Fringes of hindwing white. — The form *ruidosensis* *Cocqu.* has in the discal area of the forewing two more small spots behind the *ruidosensis*. cell, in the hindwing a small round spot in the cell and three subapical spots. Colorado and New Mexico.

G. epicharis *Drc.* (60 h) differs from all the preceding species by the loam-coloured to wood-brown *epicharis*. ground-colour of the wings, in which the typical *Gnophaela*-spots are only hazily visible. Light markings hyaline pale yellow, a longitudinal stripe at the costa of the forewing, a rectangular spot in the cell and some indistinct subapical spots. Central area of hindwing light, transverse vein and the space between the 1st and 2nd cubitus of the ground-colour. Guatemala.

8. Genus: **Josiomorpha** Fldr.

With narrower wings than the preceding genera, in the habitus similar to the *Josia*-species (*Diopitidae*) from which it is distinguished by the 2nd median being nearer to the 3rd (vein 5 nearer to 4). This mark and the course of subcosta and the anterior edge of the cell in the hindwing are often the only means to discern these *Pericopinae* from the species of *Josia*. In the latter mostly the 3rd median branch of the forewing is besides forked with the 1st cubitus, which never occurs in *Josiomorpha*. As the species of *Josia* are very frequently captured, the *Josiomorpha*, however, very rarely, we may presume the *Pericopina* to copy the other. The generic marks are like in the preceding genera, but owing to the forewing being narrowed, one vein is wanting, the 3rd radial.

J. penetrata *Wkr.* (= *longivitta* *Fldr.*) (60 f). Body black, thoracic sides in front yellow, sides of *penetrata*. abdomen yellow; abdomen beneath white. Wings blackish-brown, forewing with a broad yellow longitudinal

stripe from the base to the centre of the distal margin; the hindwing at the costa broad yellow, at the anal margin narrow yellow, but here broader than in the following. The brown groundcolour terminates far before the base in the ♀ wing, but in the ♂ it mostly reaches it. Mexico, Guatemala, Nicaragua.

triangulifera. **J. triangulifera** *sp. n.* in the habitus entirely resembles *penetrata* and may only be a race of it. Ventral side not uniformly broad white, but narrower white, on each segment the white colour narrows towards the front, so that a row of white triangles is produced. In the ♂ only the posterior segmental margins are white. Panama (Chiriqui), 2 ♀♀ in the Berlin Zool. Museum (holotype); a ♂ „South America“, a ♂ from Costa Rica in the Tring Museum.

J. erectistria Warr. (= *elisa* Drc. and *albolineata* Drc. are *Crocomela* species and therefore dealt with in the appendix on p. 452 seq.

9. Genus: **Calodesma** Hbn.

Separated from the genera hitherto dealt with by the 2nd radial of the forewing being forked with the 3rd to 5th. The 5th radial rises before the 2nd, the 1st median is not long-forked with the 2nd to 5th radials. The 3rd median in the forewing is nearer to the 2nd or midway between the 1st cubitus and 2nd median. The 1st radial rises in or behind the centre of the distance between the 2nd and 1st cubitus. It mostly contains species resembling in the exterior certain Syntomids, species of *Coreura* and *Ctenucha* (p. 155 and 189, plates 23 and 26), from which, however, they are readily separable, by the isolated vein 8 in the hindwing. In *Thyrgis* containing species of a similar habitus the 2nd radial in the forewing is separate, in *Eucyane* it rises before the 5th radial.

amica. **C. amica**. Body black, prothorax below and collar above strewn with ochreous scales. Wings blackish-brown with a red discal band of the forewing and a red marginal band of the hindwing. **amica** Stoll, from Surinam to South Brazil, has narrower bands, those of the hindwing being yet separated from the margin by a narrow black stripe; — **occidentalis** *subsp. nov.* (60 h) from Ecuador, Peru and Bolivia (type from Ecuador) has broader bands (about 4 mm maximum width), that of the hindwing passing, except at the apex, closely along the distal margin.

jordani. **C. jordani** *sp. n.* is similar to *amica amica*, somewhat smaller, fringes of the forewing at the apex and tornus beneath white; band of hindwing extending nearer to the margin. Hindwing above in the apex with a yellow spot, beneath with a white one which may also be absent; fringes of hindwing at the tips white. ♀ type from Sapucay and Villa Rica in the Tring Museum (Paraguay). The form from Matto Grosso has broader bands like in *amica occidentalis*.

rubricincta. **C. rubricincta** Dogn. resembles *amica*, body quite black, hindwing with a slight dull blue lustre, the band of the forewing is narrow, more bent (in the right forewing of a specimen there is a red longitudinal ray in the cell from the base to the band), hindwing with a broad band which is uniformly about 1 mm distant from the margin. Colombia.

chesalon. **C. chesalon** Drc. Body black, forewing as in *amica*, hindwing uni-coloured blackish-brown. (Not before me). Ecuador.

contracta. **C. contracta** Wkr. (60 h). Body black, head below, collar and ground of patagia as well as prothorax below ochreous-yellow. Wings as in *amica*, but the markings intensely yellow, sometimes warming into reddish. The bands are very variable in the different examples, those of the hindwing often only traceable or entirely absent. From Venezuela to South Brazil and Peru. The typical *contracta* has uni-coloured fringes of the ground-colour of the wings. — **itaitubae** *subsp. nov.* from Itaituba has lighter fringes, those of the apex of the forewing beneath are white. — **apicalis** *subsp. n.*, from Bahia, is similar to the preceding, the apex of the hindwing above with a yellow, beneath with a white spot.

kedar. **C. kedar** Drc. This and the following species have not been before me. Like the preceding, but the band of the forewing in front and behind partly red, that of the hindwing quite red. Colombia. (It may be a form of *Thyrgis militata* Stoll, like the following).

dilutana. **C. dilutana** Drc. resembles the preceding, the band of the forewing is yellow, that of the hindwing remote from the margin, turning reddish at the anal angle. Amazons.

collaris. **C. collaris** Drury (60 h) is like *contracta*, but the markings are white, in the hindwing sometimes dingy white, often indistinct or absent. In the ♂ the yellow colouring at the prothorax more extensive. Apex of abdomen likewise ochreous-yellow. Band of forewing shortened, only a white spot behind the cell, hindwing uni-coloured. Fringes in the ♂ white, in the ♀ black. Range as in *contracta*.

plorata. **C. plorata** Kaye is unknown to me; it is said to have only the bases of the eyes and of the palpi ochreous-yellow, otherwise like the preceding. Trinidad.

albiapex. **C. albiapex** *sp. n.* (60 h) resembles *plorata*, fringes in the ♀ white. ♂ and ♀ at the apex of the hindwing with a narrow white spot. Band of forewing oftener than in *plorata* shortened also in the ♀. Type (♂ and ♀) in the Berlin Museum from Pernambuco; Bahia. ♀ from Paraguay in the Tring Museum.

C. dioptis *Fldr.* (60 g). For this species FELDER established the genus *Chamesthema*. ♂ similar to *diopsis*. those of the preceding species, abdomen above with a white longitudinal line and below with broad whitish curls; head and patagia partly white. Forewing with a white longitudinal area behind the cell and a wedge-shaped longitudinal stripe in the cell. Hindwing with a white, black-veined central area, which may be very much darkened. Discernible from the ♂♂ of *C. collaris* *Drury* (60 h), in which also the forewing may be brightened up behind the cell, by the white dorsal abdominal line. From Venezuela to Brazil and Bolivia.

C. quadrimaculata *sp. nov.* (60 h). ♀ body as in *albiapex*, wings varying from black to brown, all the fringes white. The apices of all the wings with a white semicircular spot. Sometimes above indistinctly, beneath more distinctly a white postcellular spot on the forewing. Type in the Berlin Museum. Bolivia (type); Venezuela; Rio. The species very much resembles the Geometrid *Melanchroia cephe* *Cr.* *quadrimaculata.*

C. melanchroia *Bsd.* (61 a). Body black, head quite ochreous, thorax only in front. Wings bluish black, in each cell with white marginal spots growing longer towards the costa of the forewing. Mexico to Panama. *melanchroia.*

C. maculifrons *Wkr.* (61 a). Body above yellow, beneath white. Wings orange or yellow, the forewing with a black apical area in which there is a light spot behind the discal cell. Costal and distal margins of the hindwing black. All the wings with white longitudinal streaks at the margin. Mexico to Panama. *maculifrons.*

C. tamara *sp. n.* (61 a). ♀ more darkened than the preceding, the white marginal streaks are absent, the slanting subapical spot of the forewing is larger, all the veins broadly marked black. Type in the Berlin Museum. Upper Amazon River (Pebas; São Paulo de Olivença). *tamara.*

C. albiplaga *sp. n.* (61 a). Body black with an intense blue lustre, head laterally and collar partly with dispersed ochreous or red scales. Wings black, with a blue reflection, the forewing with a large hyaline-white subapical spot showing the veins in the ♂ finely, in the ♀ more broadly marked with black. Hindwing with traces of a corresponding spot, particularly beneath. Type (♂ and ♀) in the Berlin Museum, ♀ in the Tring Museum. Colombia. — In the habitus it reminds one of the form *alicia* *Bat.* of the Erycinid *Esthemopsis clonius* (Vol. V, p. 673). *albiplaga.*

C. eucyanoides *sp. n.* (61 a). In the habitus similar to *Esthema*. Body black with a blue lustre, dots on the head and thorax, two lateral lines and the ventral side of the abdomen bluish-white. Wings bluish-black, the forewing with a whitish hyaline subapical band of 4 or 5 spots, on the centre of the proximal margin anteriorly as far as the cell four similar longitudinal streaks above each other. Hindwing with a white, black-veined central area extending to the anal margin. Type (♂ and ♀) in the Berlin Museum. Upper Amazon River (Pebas, São Paulo de Olivença). *eucyanoides.*

C. approximata *sp. n.* ♂ similar to *eucyanoides*, abdomen beneath only with the last three rings white. The forewing only with a subapical band the anterior spots of which are larger than those behind. Traces of white longitudinal lines above the tornus. Hindwing uni-coloured, with lighter internerval stripes which terminate before the margin and are almost bluish-white there. Beneath these stripes are more distinct. Type (♂) in the Berlin Museum. Cayenne. *approximata.*

C. uraneides *Btlr.* (61 c) resembles the Erycinid *Tmetoglone dodone* *G. & S.* (Vol. V, p. 654). In its size, wing-contours and scheme of marking like *approximata*, but all the above-mentioned internerval stripes are bluish-white: in the forewing two longitudinal stripes in the cell, two longer ones and a shorter one behind the cell. Hindwing all white, except the veins, costal and distal margins being black. Abdomen above with a white dorsal line, beneath all white. French Guiana. It strikingly resembles the Erycinid *Uraneis hyalina* *Btlr.* (Vol. V, t. 138 e). *uraneides.*

10. Genus: **Ephestris** *Hbn.*

Veins chiefly agreeing with those of *Calodesma*, but the 1st radial of the forewing rises before the centre of the distance between the 1st and 2nd cubitus; the latter two veins converge from their origin towards the margin. Only one black and yellow species:

E. melaxantha *Hbn.* (61 b). Both sexes agreeing in colour and marking which is to be seen from the figure. Brazil. *melaxantha.*

11. Genus: **Cyanohypsa** *Giac.*

On the whole in the veins similar to the two last genera, distinguished from them and all the other *Pericopinae* by the 2nd median branch in the hindwing rising midway between the 1st and 3rd, scarcely nearing the 3rd.

C. stefanelli *Giac.* (61 a) is bluish-black, the collar, terminal tufts of the thorax and abdominal apex ochreous-yellow. Wings steel-blue, the forewing in the centre with two round white spots below each other. Peru, Argentina, Paraguay. *stefanelli.*

12. Genus: **Isostola** Fldr.

Veins agreeing with those of *Ephestris*, but the 1st and 2nd cubitus of the forewing run parallel or diverge towards the margin. All the species are black, with a lustrous blue colour, with whitish hyaline markings. They resemble certain *Syntomidae* (*Agyrta*, *Cyanopepla*, t. 24), *Dioptridae* (*Phanoptis*) or *Geometridae* (*Gonora*).

- divisa*. **I. divisa** Wkr. (61 c). The hyaline spot before the centre of the forewing behind the cell does not extend to the base, the hyaline central spot of the hindwing is the broadest before the centre of the wing; —
vicina. in the form **vicina** Btlr. the postcellular spot of the forewing extends to the base of the wing, the central spot of the hindwing is the broadest in or behind the centre. From Venezuela to South Brazil and Peru.
- flavicollaris*. **I. flavicollaris** sp. n. resembles the preceding, but on the collar there are instead of the white dots two yellow spots. The discal band of the forewing is longer, more uniformly broad, in front not pointed. Panama. ♂ type from Chiriqui in the Berlin Museum.
- dilatata*. **I. dilatata** sp. n. Wings on the whole broader than in *divisa* (61 c). The discal band of the forewing is very broad, occupying yet a part of the discal cell, at the proximal margin somewhat narrower. Collar with two white dots, basal joint of the palpi and prothorax like in *divisa* below red (in *flavicollaris* yellow). In this species and the following *tenebrata* the central area of the hindwing is expanded towards the proximal margin, so that the black border runs almost parallel to the margin, whilst in the first two species it is widened at the anal angle. Panama. ♀ type from Chiriqui in the Berlin Museum.
- tenebrata*. **I. tenebrata** sp. n. (61 c) resembles *dilatata*, but the forewing is as far as the discal band uni-coloured blackish-blue. The latter does not extend into the discal cell. Bolivia. ♀ type from Puerto S. Rosa (GARLEPP) in the Berlin Museum.
- nigrivenata*. **I. nigrivenata** sp. n. (61 c) resembles *divisa*, but the collar above with 2 red spots, the veins of the discal band are broadly bordered with black, like those of the hindwing. Colombia, Ecuador. ♂, ♀ type (Colombia) in the Berlin Museum.
- philomela*. **I. philomela** Drc. has remained unknown to me in nature. It is said to have the cell quite hyaline, without the red spots of the collar, otherwise like the preceding. Central Colombia.
- In the following species the subapical band is absent.
- rhodobroncha*. **I. rhodobroncha** Fldr. Collar with 2 white spots above, wings black, with a blue reflection; the forewing only with a white discal band, the hindwing with a greyish lustrous central area. Expanse of wings: 46 mm. Amazons.
- superba*. **I. superba** Drc. resembles *rhodobroncha*, the forewing with a basal, the hindwing with a central whitish hyaline area. Panama, Guatemala.
- thabena*. **I. thabena** Dgn. Collar without white spots, with red scales. Otherwise similar to *rhodobroncha*, the veins in the discal band of the forewing broadly black. Hindwing uni-coloured. Colombia.
- I. lydia** Drc. (*Phanoptis*) is probably a Syntomid.

13. Genus: **Josiomorphoides** gen. nov. *Dioptrids*

Posterior tibiae with 2 pairs of spurs, in the forewing the 2nd to 5th radial branches are forked (in *Josiomorpha* the 2nd radial rises separately), the 2nd radial rising before the 5th, the 3rd palpal joint but slightly shorter than the second. In the hindwing the radial ramus and the 1st median branch are forked, the other veins rising separately. The species known resemble Dioptrids (*Josia*) in just the same way as the species of *Josiomorpha* do. Generic type: (*Josia*) *gigantea* Drc.

- gigantea*. **J. gigantea** Drc. (= *flammata* Dgn.). Body black, with a blue lustre, patagia on the ground and collar laterally yellow, thorax above with a yellow median line. Abdomen above and laterally with yellow longitudinal lines, beneath whitish. Forewing with a yellow longitudinal line from the base of the proximal margin, in the ♂ ending before the margin, in the ♀ on it. Hindwing likewise black with a yellow longitudinal stripe, the abdominal margin yellow. Colombia. — Size and colouring similar to that of *Josiomorpha penetrata*, p. 431, t. 60 f.
- dognini*. **J. dognini** sp. n. The ♂ mentioned by DOGNIN as *flammata* belongs to a different species; from the preceding distinguished by broader yellow longitudinal stripes and the absence of the yellow dorsal side and white ventral side of the abdomen. Colombia.

14. Genus: **Sagaropsis** gen. nov.

Chiefly agreeing in the structure with *Josiomorphoides*, the 3rd palpal joint being a third to a half of the second. Black species with yellow markings, the wings being shorter and broader than in the preceding genus. The imagines resemble Dioptrids in the habitus. Generic type: (*Sagaris*) *horae* Drc.

S. horae Drc. (61 b). Black, with a blue lustre, particularly at the base of the wings. Forewing with *horae*, a yellow transverse band to the tornus. Guatemala, Panama.

S. monotona sp. n. is like *horae*, but without any blue lustre. ♀ type from Pebas in the Berlin Museum, *monotona*. ♂ type from the Rio Huacamayo (Peru) in the Tring Museum.

S. elegans sp. n. (61 b) is similar to *horae*, the band removed farther towards the base, terminating *elegans*. behind on the axillaris. Forewing at the base and abdomen with a more intense blue lustre. Beneath the yellow band is behind distally more expanded. Bolivia. ♂ type in the Berlin Museum.

S. brevifasciata sp. n. (61 b) is like *elegans*, the yellow band in front shortened, only extending to the *brevifasciata*. cell. Rosario; St. Inez, 1250 m. ♂ type in the Tring Museum.

S. centralis sp. n. (61 b). Body black, yellow spots on the collar and tips of the patagia, yellow *centralis*. longitudinal lines on the thoracal and abdominal dorsum, the abdomen with similar lateral stripes and white ventrum. Wings yellow, all the margins yellow, the distal margin of the forewing broadly blackish-brown. Venezuela, Valencia. ♀ type in the Berlin Museum.

S. palmeri Drc. (61 b). In the habitus similar to a *Crocomela* (*Darna*). Body black, with a blue lustre; *palmeri*. abdomen beneath ash-grey. Wings black with a blue lustre extending on the hindwing almost to the margin, on the forewing near to the yellow discal band. The latter ends shortly before the tornus, and is 4 mm broad at the costa, 6 mm at the broadest place. Ecuador.

S. rhombifera Dgn. (61 f). Body black, abdomen with a blue lustre and yellow lateral stripe. Wings *rhombifera*. black, with a blue lustre, with a yellow trapezoid central spot, which on the forewing irregularly pierces the black costal margin. Colombia.

S. tolimata Dgn. is unknown to me, but it presumably belongs to this species. Collar and patagia *tolimata*. with yellow spots. Forewing similar to those of *rhombifera*. Hindwing quite black, with a blue lustre. Colombia.

15. Gattung: **Eucyane** (*Esthema* Hbn.).

Posterior tibiae with 2 pair of spurs, 3rd palpal joint at most one third of the second, in the forewing the 2nd to 5th radial branches are forked, the 2nd rising before the 5th, the other veins being like in the preceding genera. Black species often exhibiting an intense blue lustre, with white, yellow or red markings.

1. Wings above without red spots or bands.

E. aletta Stoll (61 c). Black, with a blue lustre, head and thorax with white dots, ventrum white. *aletta*. Wings of the colour of the body, the forewing with a subapical band of white spots, which are pointedly extended towards the base on the hindwing. From Panama to Ecuador and Surinam, San Domingo.

E. euploeodes Btlr. (61 d). The white submarginal stripes extend on the hindwing to the margin. *euploeodes*. Costa Rica, Panama, Colombia.

E. speciosa Wkr. (= *herrona* Btlr.) (61 d). Blackish-blue, with white discal bands, which are broadly *speciosa*. crossed with black by the veins. Fringes at the apex and partly at the tornus white. Ventrums blue with white segmental margins. — In the form **venosa** Fldr. the discal band of the hindwing is expanded to the base, so *venosa*. that the hindwing appears white with a blackish-blue margin. Colombia and Upper Amazon River.

E. confluens Btlr. (61 d) is similar to *venosa*, on the hindwing the basal area is blue, the veins are *confluens*. narrowly black. Ventrums more extensively white. Bolivia; Iquitos.

E. eulalia Drc. (61 d) is likewise similar to *speciosa*, ventrum blue with quite narrow white segmental *eulalia*. margins. The discal bands are less broadly crossed by black, those of the hindwing are farther distally removed.

E. celadon Cr. (= *anacharsis* Bsd.) (61 d). Blackish-blue, forewing with a white postdiscal band, *celadon*. which is parted by narrow black veins. Hindwing above only with traces of an antenarginal band of white spots, whilst beneath it is sometimes distinct. Ventrums uni-coloured blackish-blue. Fringes as in the preceding species. Nicaragua to Surinam.

E. pylotis Drury (= *celina* Bsd.) (61 e) resembles *celadon*, but the ventrum exhibits 5 yellow rings, *pylotis*. the discal band of the forewing has quite white veins, the fringes of the hindwings are all white. Mexico, Guatemala, Honduras.

E. pylotoides sp. n. is quite similar to *pylotis* (61 e), the forewing is more brownish-violet, the band *pylotoides*. is more strongly bent and narrower (at the broadest part 3 mm), hindwing beneath in the centre of the costa with a red spot. The ventral rings are red, narrower. Mexico. ♀ type in the Tring Museum.

- escuintla*. **E. escuintla** Schs. above resembles *pylotoides*; hindwing beneath behind the red spot with a row of small white spots extending straight as far as vein 3, from where they bend inward. Guatemala.
- rhaetia*. **E. rhaetia** Drc. (61 e). Body blackish-blue, the last 5 abdominal segments in the centre red. Wings black, at the base with a particularly intense blue lustre. Discal band behind the cell narrow, parted black by the veins. Hindwing only with the beginning of a submarginal band (up to four spots). Fringes of the hindwings and at the apex of the forewing white. Colombia. *Bolivia*
- rhea*. **E. rhea** Dogn. has remained unknown to me, it may be only a form of the preceding. The white band of the forewing more towards the base, so that the transverse vein is about in its centre, the band of the hindwing is likewise more proximal, so that its first spot in front is 6 mm distant from the end of the subcostal. Colombia.
- The species following now have two bands on the forewing:
- rhamses*. **E. rhamses** Dgn. resembles *rhaetia* (61 e), the spots of the hindwing are somewhat more proximal, the fringes of the hindwing between the 1st median and the 1st cubitus black. Colombia.
- bicolora*. **E. bicolora** Sulz. (= *crocota* Drc., *dichroa* Hbn.) (61 e). Base of the wing with several longitudinal stripes irrorated with blue, the discal band is straight, distinct, broadly parted black by the veins. Apical spot large. With or without a white spot between the bands. Internerval stripes of the hindwing narrow, two stripes in the cell. Fringes black, ventrum white. Guiana to South Brazil and Peru.
- simulata*. **E. simulata** Wkr. (= *mimica* Wkr.) (61 e). Base of the forewing without distinct longitudinal stripes, the discal band in the centre mostly interrupted, the cell of the hindwing at most with traces of longitudinal stripes. Venezuela, Colombia, Brazil.
- plagifera*. **E. plagifera** Fldr. (= *uranigera* Wkr.) (61 e). Body and forewing as in *bicolor* Sulz., at the base of the forewing only a blue stripe on the proximal margin. Basal area of the hindwing blue, with a broad discal band, which only extends to the anterior edge of the cell, broadly parted black by the veins. Bolivia, Amazons, East Peru.
- strigifera*. **E. strigifera** sp. n. (61 f). Forewing as in *plagifera*, in the hindwing the white stripes extend farther distally, whereby it resembles *bicolor*, the stripes of which, however, are much narrower and not so purely white. Itaituba. ♀ type in the Berlin Museum.

2. Wings with red spots or bands.

a) Forewing with a white discal band.

- albimacula*. **E. albimacula** Drc. (61 f). Body blackish-blue, with 5 red rings on the ventral side of the abdomen. Forewing violettish-brown, without red spots, except perhaps the costa at the band narrowly reddish. Hindwing bluish-black, in the anal half with a blue reflection, on the centre of the costa with a red spot extending to the cell. Fringes as in the following white at the apex of all the wings and partly at the distal margin of the hindwing. Mexico, Honduras.
- diana*. **E. diana** Btlr. (61 f). Wings at the base with an intense blue lustre. Forewing at the costa with a red spot joining directly the proximal side of the band. Behind the red spot of the hindwing 2 or 3 more forming a slanting band. Colombia, Amazons, Guiana, Venezuela, Brazil.
- uranicola*. **E. uranicola** Wkr. resembles *diana*, the bands are narrower (at the broadest part 2 mm), those of the forewing mostly only extending to the axillaris, terminating a little before the tornus. Colombia.
- rubrifascia*. **E. rubrifascia** sp. n. resembles *diana* (61 f), the band of the hindwing is quite red. ♂ type from Manicoré in the Berlin Museum.
- glauc*. **E. glauca** Cr. (61 f) resembles *diana*, the band of the forewing, particularly in front and behind, with a pink shine. In the hindwing the whole band or only the foremost spot of it is red. Upper Amazon River.

The following species are wanting the intense blue lustre at the base of the forewing:

- turbida*. **E. turbida** sp. n. resembles *diana* (61 f), without the blue lustre at the base of the forewing, where there are only single greenish-blue particles of dust. Wings broader. Colombia. ♀ type from Cauca in the Berlin Museum.
- excellens*. **E. excellens** Wkr. (= *hermaea* Drc.) (61 e). Forewing brownish-violet, dull, at the costa with a red spot which does not touch the discal band. Hindwing with a white slanting band extending into cell 2 or 3, beneath with a red costal spot, with an intense blue lustre. Venezuela, Colombia.
- reedia*. **E. reedia** Schs. is like the preceding, presumably only a form of it, with a red spot also at the tornus of the forewing. Costa Rica, ? Venezuela.
- rubrimaculata*. **E. rubrimaculata** sp. n. In the wing-contours and scheme of markings similar to the preceding, forewing browner, the red costal spot on the forewing touches the band, a second red spot at the tornus. Band of the

hindwing composed of 2 or 3 red spots, only extending to the 2nd median. Venezuela. ♂ type from Maracaibo in the Berlin Museum.

W. joiceyi Dgn. Forewing black, marking as in the preceding, hindwing with larger spots (red or *joiceyi*, white?), extending to the 1st cubitus. Colombia.

E. drucei Schs. (61 f). Ground-colour of the wings as in *rubrimaculata*, the red costal spot of the forewing *drucei*, distantly remote from the band which is broader than in the two preceding species (maximum 5 mm). Hindwing with a red costal spot and some adjoining white spots. Venezuela to Costa Rica.

E. dejanira Drc. (61 g). Ground-colour of both wings bluish-black, the white bands in the forewing *dejanira* and hindwing very broad, the red costal spot remote from the band, a similar one on the hindwing beneath. Colombia.

b) Discal band of the forewing yellow.

E. arcaei Drc. (61 g) entirely resembles *E. albimacula* Drc. (61 f) with the exception of the yellow *arcaei* band. Honduras, Panama.

c) Discal band of the forewing red.

E. temperata Wkr. (= *jucunda* Fldr., *egaensis* Btlr.) (61 g). Black, with a blue lustre, the last *temperata*, 5 ventral segments red, edged with white. Base of all the wings with a blue lustre, fringes at the apex white, partly also on the hindwing. Discal band of the forewing pale red, at least at its broadest place. $3\frac{1}{2}$ mm broad; the oblique band of the hindwing likewise red and rather broad. From Guiana and Colombia to South Brazil.

E. hystaspes Btlr. (61 g) is similar to the preceding, the discal band of the forewing is dark red, *hystaspes*, narrower, never extending into vein 3. Band of the hindwing narrow, broken up into spots, sometimes being absent, but in this case there is beneath at least one red spot. Venezuela.

E. chalybea sp. n. resembles *hystaspes* (61 g), the discal band of the forewing extends to the tornus, *chalybea*, whereas in the two preceding it terminates at the axillaris, about as broad as in *temperata*. The band of the hindwing is long, more remote towards the margin than in the allied species and more parallel to the margin, extending into cell 2; not broken up into spots. Under surface like the upper. ♀ type from the Rio Songo (Bolivia) in the Berlin Museum.

E. calida Fldr. (61 g). Forewing without an intense blue lustre at the base, only strewn with greenish-blue scales. Discal band of the forewing extending to the posterior margin, dark red; band of the hindwing as in *temperata*, sometimes wanting above. Colombia.

E. meres Drc. Body in this species and the following quite black, abdomen with a blue lustre. Forewing *meres*, black, with a red line from the costa to the tornus beyond the cell. Hindwing black, with a blue lustre. Colombia. (This species was not before me.) — *E. constrictifascia* Dgn. which was mentioned in the genus *Thyrgis* (p. 428), may also belong hereto.

E. ambigua sp. n. (61 g). Body and wings of the same ground-colour as in *meres*, but the forewing *ambigua*, is violettish-brown. A flesh-coloured discal band runs rather straight across the last quarter of the discal cell to the tornus. Hindwing with a peculiarly dull blue lustre. Honduras. ♂ type in the Berlin Museum.

E. gundlachia Schs., from Cuba, has remained unknown to me and is doubtfully placed here. *gundlachia*.

16. Genus: **Pericopis** Hbn.

In this genus we also comprise the *Chetone* Bsd., *Sermyla* Wkr., *Dysschema* Hbn. (partly), and *Thebrone* Bsd., because these genera are only founded upon coloristic marks and are therefore of subgeneric value at most. It is the most polytypical genus of the subordinate family, in the colouring, marking, and wing-contours particularly copying species of *Heliconius* with which they also fly together. Sometimes the screening hue only refers to the ♀♀. In this genus and the following genera the posterior tibiae only exhibit terminal spurs denoting a more continuous specialization corresponding with the mimetic habitus. In the forewing the 2nd radial branch rises separately, but mostly anastomoses with the forked radial branches 3 to 5. The 5th radial rises before the 3rd. The pinnae of the ♀ antennae are shorter than the diameter of the shaft, whereby the genus differs from *Phaloë* and others. The ♂♂ are often different from the mimetically coloured ♀♀; this sexual dimorphism is not yet known in all the species, so that later on probably some species will have yet to be combined.

1. Abdomen above uni-coloured, without a darker median line, without hardly any sexual dimorphism. ♂ forewing without diffuse hyaline stripes, with welldefined bands and spots (= *Chetone* Bsd.).

- catilina*. **P. catilina** Cr. (= *nasica* F., *perspicua* Wkr.) (62 a). Wings blackish-brown, markings greenish-yellow with white marginal dots. Body above blackish-brown, beneath sand-coloured. Brazil, Colombia, Guiana.
- conjuncta*. **P. conjuncta** sp. n. (62 a) is quite similar to *catilina*, forewing at the base behind the cell with a large greenish-yellow spot, the posterior edge of the cell and 2nd cubitus very broadly black, whereby the discal band is divided into 3 large spots. On the hindwing the transverse vein is not broadly marked black, and therefore the light spot distally to the cell coheres with the yellow ground-colour. Colombia. ♀ type from the Rio Dagua in the Berlin Museum.
- ithomia*. **P. ithomia** Fldr. (62 a) is rather variable, head and thorax black, dotted white or yellow, abdomen blackish-brown, at the base more or less ochreous-brown, beneath straw-coloured. Forewing blackish-brown, in the basal area without or with ochreous-brown longitudinal stripes at the costa and on the fold. Discal band composed of ochreous, yellow or white spots, a likewise yellow or white subapical band, a series of large similar marginal spots. Hindwing ochreous, costa basally and distal margin broadly black, with yellow or white marginal spots. Panama, Honduras. It copies *Heliconius zuleika* Hew. (Vol. V, t. 74 c) flying in the same region.
- kenara*. **P. kenara** Btlr. (= ♂ *salvini* Fldr., *Drc.*) (62 a). Forewing similar as in *ithomia*, the apical spots smaller. Hindwing likewise similar to the preceding, but the veins and costa quite black. Forewing beneath at the base broadly ochreous-yellow, with a black cellular spot. — The form **separata** form. nov. (62 b) has the band of the hindwing broken up into broad black streaks on the veins. Panama, Colombia, Venezuela.
- angulosa*. **P. angulosa** Wkr. (62 b). Scheme of markings in the forewing as in *ithomia*, but the base of the forewing is broadly ochreous-brown, with a black wedge in the cell. Discal band at least behind the cell ochreous-brown. Hindwing as in *ithomia*. Veins finely black. Colombia, Venezuela. — **heliconides** Bsd. (= *irenides* Btlr.) (62 b) from Central America (Honduras, Panama) has the wedge at the base of the forewing connected with the bordering of the ochreous-brown area.
- suprema*. **P. suprema** sp. n. (62 b). Body and forewing as in typical *angulosa*, the yellow discal band of the forewing is much broader, light brimstone-coloured, steeper; it terminates considerably far before the proximal angle. Margin of the hindwing much broader black, its proximal edge going across the transverse vein. Costa not black. Colombia, Ecuador. ♂ type from Rio S. Juan in the Berlin Museum, ♀ paratype from Zamora in the Tring Museum.
- phaeba*. **P. phaeba** Bsd. (= *ithrana* Btlr.) (62 c). Head and thorax black, dotted white and ochreous, abdomen above brown, beneath straw-coloured. Forewing blackish-brown, at the base one or several longitudinal lines varying from red to ochreous-brown, with a yellow broad discal band ending obtuse at the 2nd cubitus or pointed behind it, 1 to 4 yellow subapical spots and a series of white marginal spots. Hindwing with a broad black costal margin and distal margin, in the latter a series of marginal spots varying from ochreous-yellow to red-brown, the veins thickly black, otherwise ochreous-yellow to red-brown. Guatemala to Colombia, Ecuador, Peru, Upper Amazon River. — In the form **intersecta** form. nov. (62 c) the marginal band of the hindwing is broken up into thick black streaks which are situate to the right and left of the ends of the veins; the basal parts of the veins are less thickly black. As this form only occurs in the Amazon District and Eastern Peru, it is perhaps the southern race of the species, but perhaps also a distinct species. It copies *Heliconius aoede* Hbn. (Vol. V, t. 76 f).
- meta*. **P. meta** Drc. is unknown to me in nature. Quite similar to *intersecta* (62 c), but the head and thorax are black, the hindwing in the ground-colour pale yellow. Colombia.
- phyleis*. **P. phyleis** Drc. (62 c) varies a great deal in the different specimens. Head and thorax similar to *phaeba*, but abdomen beneath chocolate-brown. Forewing blackish-brown, at the base of a variably extensive ochreous colour. A broad brimstone-coloured discal band rarely extends somewhat beyond the 2nd cubitus, some yellow or white submarginal dots. Hindwing blackish-brown, with reddish-brown or ochreous-brown internerval stripes which are often very much reduced. Colombia, Ecuador, Peru, and Bolivia. It copies *Heliconius melete* Fldr. (Vol. V, 77 b).
- mimica*. **P. mimica** Fldr. (62 c) is similar to *phyleis*, the brown dusting on both wings is much scantier, the hindwing being sometimes uni-coloured black, a subapical row of spots is parallel to the discal band, marginal spots are wanting. Colombia.
- isse*. **P. isse** Hbn. (62 d). Body coloured as in most of the species of this subgenus, forewing blackish-brown, rarely at the base with two ochreous-brown longitudinal lines; discal line narrow, uniform, extending to the axillaris, a subapical band composed of 3 yellow spots, and white marginal spots. Hindwing ochreous-yellow, with black veins and a narrow black margin, before this a broad black band which is distally extended on the veins and connected there with the margin; costa likewise black, analis and stripes before and behind it likewise black. Brazil.
- decisa*. **P. decisa** Wkr. (62 d) is similar to *isse*, the discal band is narrower, behind more pointed, subapical spots hyaline, shaded somewhat with yellow. Discal cell of the hindwing and partly its surroundings brimstone-coloured. South Brazil.
- studyi*. **P. studyi** sp. n. (62 d) is likewise similar to *isse*, 3 wood-coloured longitudinal lines at the base of the forewing, all the markings hyaline, the discal band broader, behind tapering, terminating a little before

the axillaris. Hindwing as in *isse*, but more red-brown. Abdomen beneath dusted somewhat blackish. Colombia. It was denominated in honour of E. STUDY, the well-known mimicry-explorer. ♀ type in the Berlin Museum.

P. histrio Fldr. (62 c). Ground-colour of the wings brown, the forewing basally with 5 or 6 black longitudinal stripes, a black spot at the cell-end, opposite which a similar one is at the costa, 2 or 3 black spots between the 2nd cubitus and the 3rd median branch; apical part black, with a marginal line of yellow and white spots. At the costa a yellow spot and a yellow band of a variable extent. Hindwing on two thirds of the costa, in the cell, distal margin and proximal margin black, with yellow or brown submarginal spots. Fringes at the apex white. Amazon River. — In the form **eugenia** Drc. (62 e) the yellow band of the forewing is absent, and its apical part is much narrower black. *P. histrio* copies *Heliconius euphonia* Fldr. and *Lycorea ceres* Cr. (Vol. V, t. 31 c).

P. hydra Btlr. (62 e) is quite similar to *histrio*, but larger, the apical part of the forewing is broader black, at the apex there are no light spots. Hindwing black, with a brown costal spot before the apex and small yellow submarginal spots. Fringes at the apex white. Ecuador, Peru. — **histriomorpha** form. nov. has hindwings entirely resembling those of *histrio*, but the black margin of the hindwing is narrower. ♀ type from Zamora in the Tring-Museum. — *P. hydra* copies *Heliconius aristiona* Hew. and *messene* Fldr. (Vol. V, t. 73 d).

P. felderi Bsd. (62 f). Forewing black, at the base extensively red-brown, so that only a basal wedge in the cell, and the proximal margin remain black. Across the cell-end a band of 2 hyaline spots to which a bent brown spot is joined. A postdiscal and a submarginal row of spots are likewise whitish-hyaline. Hindwing red-brown, with a black margin, which exhibits a series of white submarginal spots. Colombia.

P. salvini Fldr. Base of forewing red-brown, black longitudinal stripes on the veins and in the cell, the rest of the wing being blackish, with red-brown traces. A yellow costal spot in two thirds of the cell, a similar one right behind it, extending to the 3rd median vein, behind it continued by two yellow dots, a submarginal row of white spots. Hindwing red-brown, the costa and distal margin broadly black, the submarginal row of spots and a spot at the apex white. Panama.

2. Abdomen in the ♀ (sometimes also in the ♂) above uni-coloured, mostly a distinct sexual difference in the colouring, ♂ often with hyaline places on the forewing. Costa at the base not with a conspicuous light streak (*Thebrone* Bsd.).

P. tricolora Sulz. (= *turbida* Wkr., *aglaure* Cr.) (62 d, e). Body blackish-brown, abdomen beneath in the ♂ entirely pale yellow, in the ♀ partly pale yellow at most; dorsum of abdomen in the ♂ varying from yellow to a bluish grey, with a black dorsal line. Base of collar and of patagia in the ♂ (very rarely in the ♀) with yellow spots, ♀ on the mesothorax sometimes with a whitish spot. Forewing blackish-brown, with hyaline places. Hindwing in the ♂ whitish hyaline, the costa, distal margin and transverse vein broad black, at the anal angle traces or spots; in the ♀ at the anal angle a red band extending to the 1st cubitus, distally to the cell a yellow spot, otherwise the hindwing blackish-brown. The races are distinctly ascertainable only by the ♀. The typical form from Guiana, the Amazons and East Peru has in the hindwing the anal band pink, more or less distinctly broken up into single spots; the hyaline bands of the forewing are indistinct. The ♂ has almost invariably whitish hindwings, without red spots at the anal angle. — **jansonis** Btlr., from Panama, Colombia, Venezuela, generally has shorter and broader wings, in the ♀ the brick-red band of the hindwing is uniform behind the 2nd cubitus, not broken up into spots. The bands of the forewing exhibit a yellow or brownish tinge and are more distinct. In the ♂ there are often red spots at the anal angle of the hindwing. — The ♂ form **flavopennis** Rbl. has yellow instead of white hindwings. — The Colombian ♀♀ mostly exhibit yet in the cell some yellow scales, thus forming the transition to the form **salome** Drc. (= *albisarta* Prout) (63 a) from Ecuador and Bolivia. Here there is also proximally to the transverse vein another yellow spot. — In South Brazil flies **lunifera** Btlr.; in the ♀ forewing only the apical band is hyaline, hindwing with a short anal band and a large yellow spot of 5 mm diameter, which is not parted by black veins.

P. nigriventralis Dgn. (63 a). ♂ similar to that of *tricolora*, in the forewing the discal band and subapical band are fused behind the cell; hindwing with a broader border containing white submarginal dots and before it a series of rust-brown indistinct spots. Collar and patagia darker. The yellow under surface of the abdomen with a black longitudinal line. ♀ unknown. Upper Amazon River.

P. hypoxantha Hbn. (= *sibylla* Btlr.) (63 a). ♂ similar to *jansonis*, hindwing yellowish to red-brown hyaline, with a submarginal row of white spots, before them sometimes rust-brown spots. Transverse vein narrow black, in front broader at most. Base of wings without the red spots exhibited in the preceding species. In the forewing the discal band and subapical band are at least connected above. Colombia, Venezuela, Brazil, Bolivia, Peru.

P. thyridina Btlr. (= *unxia* Drc.) (62 d). ♂ similar to *hypoxantha*, the margin of the hindwing above and beneath without the rust-brown marking, the discal area paler yellow, collar and patagia with smaller yellow spots. Ecuador, East Peru and Bolivia.

P. nigrivenata sp. n. (62 c). ♂ similar to the preceding, hindwing with black veins, also the cell longitudinally parted by black lines. Forewing without white submarginal spots, all the black markings, particularly beneath, with rust-brown patches. Collar and patagia as in *hypoxantha*. Ecuador, ♂ type in the Berlin Museum.

- evanescens.* **P. evanescens** *sp. n.* (63 a). ♂ similar to the preceding, somewhat larger (forewing 30 mm long), all the white dots and rust-brown markings are absent. Brazil. ♂ type from Casa Branca in the Berlin Museum.
- ccialis.* **P. ccialis** *Drc.* (63 a, b). ♂ similar to *tricolora*, transverse vein of the hindwing only very narrow black, its margin with a submarginal row of white spots, before which there is a row of glaring red spots as far as the apex. ♀ with a distinct discal band and uniform subapical band on the forewing, in the hindwing the red band extends to the apex, at the margin a row of white spots. Costa Rica, Panama, Colombia.
- lucifer.* **P. lucifer** *Btlr.* (63 a). ♂ similar to *tricolora* (62 d, e), collar and patagia less yellow, ventrum with a black median line. Hindwing with broader black margins, also the proximal margin as far as the cell darkened by blackish. Brazil, ? Venezuela.
- subapicalis.* **P. subapicalis** *Wkr.* (= *tristis* *Wkr.*) (63 b). ♀ body blackish-brown, anal tuft ochreous-yellow. Forewing blackish-brown, proximal margin and a band at $\frac{1}{3}$ darker, a hyaline broader transverse band distally to the cell; hindwing jet-black, with a dull dark blue reflection, a row of white marginal spots, the largest at the apex and anal angle. ♂ (= *noctuites* *Btlr.*) collar with yellow spots, patagia with red spots, abdomen yellow, above with black longitudinal lines and black transverse lines on the segments, anal tuft ochreous-yellow. On the forewing the hyaline places are enlarged; the distal margin is broad blackish-brown, the proximal margin broad trapezoidal dark, of the transverse band particularly the spot in the centre of the cell, as well as the costa and transverse vein are blackish-brown. Hindwing quite hyaline white, costa and distal margin broad black; — in the male form **parnassioides** *Wkr.* the ground-colour of the hindwing is yellow. Brazil; ? Venezuela.
- fantasma.* **P. fantasma** *Btlr.* is a well recognizable species. Body similar to that of *parnassioides*, but abdomen beneath brown, only laterally narrow yellow. Forewing with yellowish to brownish more thinly scaled places: a band from the tornus towards the cell-end, broadly forked blackish-brown by the transverse vein; the base the same, separated from it by a feebly blackish band, distal margin and proximal margin particularly dark. Ground-colour of the hindwing and of the abdomen above radiantly yellow, the costa black, transverse vein broadly black, the distal margin and proximal margin broadly black, the latter with yellow longitudinal stripes, the margin with some red scales at the anal angle, anal tuft red. Expanse of wings: 50 mm. Colombia.
- larvata.* **P. larvata** *Wkr.* (62 f). ♀ body blackish-brown, abdomen beneath yellow with a broad black median line. Forewing blackish-brown, with a hyaline discal and subapical band, the latter in front pointed. Hindwing brimstone-coloured, costa, veins and margin black, the latter broad, extending to beyond the transverse vein and containing a yellow spot distally to the transverse vein as well as some red spots from the anal angle towards the centre of the wing. Guiana, Amazons.
- formosissima.* **P. formosissima** *Btlr.* (62 f). ♀ body as in *larvata*, the forewing almost uni-coloured brown, the hindwing blackish-brown, with a row of yellow spots distally to the cell and some red spots at the anal angle. Amazons, Putumayo.
- buckleyi.* **P. buckleyi** *Drc.* resembles the preceding, body black, hindwing only with three yellow spots (between the 2nd median and the radial ramus), the red anal band extending to the 3rd median. Ecuador.
- rosina.* **P. rosina** *Btlr.* (63 b) is similar to *jansonis* *Btlr.* Bands in the forewing mostly connected, in the hindwing the pinkish-red spots are continued to the apex, the yellow ones are wanting. Upper Amazon River.
- leucophaea.* **P. leucophaea** *Wkr.* (= *rubrimargo* *Bsd.*, *salvatoris* *Bsd.*) (63 b) is somewhat like *rosina*; collar and patagia spotted yellow or white; in the ♀ forewing almost uni-coloured brownish-black, in the ♂ the usual hyaline places, in the ♂ and ♀ the hindwing is blackish-brown, with a band of red spots being here situate more towards the margin and more continuous than in *rosina*, behind it a marginal row of white spots. — The form **flora** *Btlr.* has in the ♂ twice as broad red bands, in the ♀ the forewings show bright markings like in the ♂ (from Guatemala). — Mexico to Nicaragua. — Larva pale straw-coloured with lateral, subventral and ventral purple brown lines, traces of similar subdorsal and stigmatal lines. Transverse bands of broad purple spots on the segments 3, 5, 11 and 13, a lateral spot on segment 6. Tubercles orange, hairs black, some on segments 3 and 4, 12 and 13 longer than the others. — The ♀ resembles the species of *Didonis* (Nymphalidae; Vol. V, t. 94 f, of which tori emitting an offensive smell were described), which therefore probably form the model of the species.
- damon.* **P. damon** *Drc.* remained unknown to me. ♀: body black, head, collar and patagia spotted white, abdomen above black, beneath yellowish-white. Forewing dusky hyaline, apex, distal margin, proximal margin, and two transverse bands black, veins also black. Hindwing yellowish-white. Distal margin broad black with white submarginal spots. Transverse vein broad black, veins black. Expanse of wings: 85 mm. Peru, Chanchamayo.
- semirufa.* **P. semirufa** *Drc.* is neither before me. ♀: body black, collar with yellow spots, base of patagia also yellow. Abdomen above red-brown, beneath yellow. Forewing similar to that of *damon*. Hindwing reddish hyaline, with a black distal margin containing white submarginal spots and before them a red band. Beneath the forewing shows a red apical band and a red spot at the tornus, the hindwing a red costal margin. Like the preceding. Perhaps both are female forms of *hypoxantha* *Hbn.* (63 a).

P. sylvia Drc. is unknown to me. ♀: body black, collar and patagia dotted white. Abdomen above *sylvia*. grey, beneath pale yellow. Forewing like in the preceding, a red-brown line on the proximal margin, some white subapical spots. Hindwing whitish hyaline, veins and the broad transverse vein black. Distal margin broad black with white submarginal spots. Beneath the costa is chrome-yellow. Size and range as in the preceding.

P. terminata Guér. Body blackish-brown, abdomen beneath only with two narrow yellow lines, patagia *terminata*. with a red dot. Wings blackish-brown, forewing with a narrow yellowish transverse band extending from the costa to the tornus and being somewhat reddish at the ends. Hindwing with a broad red marginal band parted black by the veins. Fringes partly black. Forewing beneath in the centre with a yellow spot, hindwing beneath on the inner side of the red marginal band bordered with yellow, the latter band mostly paler. — The form **holofermes** Btlr. (62 f) is wanting the yellow spots beneath. Brazil: Rio. *holofermes*.

P. marginata Guér. (63 c) resembles the preceding, but in the forewing the transverse band extends *marginata*. towards the centre of the distal margin, not to the tornus. The ♂ has uni-coloured blackish-brown hindwings. Anal tuft orange, not red like in *terminata*. Brazil: Leopoldina, São Paulo.

P. constans sp. n. (63 c). ♂ and ♀ almost uniform. Body blackish-brown, collar and patagia spotted *constans*. ochreous-yellow, abdomen above blackish-violet, beneath white. Wings similar as in *tricolora*-♂, the dark portions, however, irrorated bluish, fringes of hindwings white, margin of hindwing in the ♀ narrower than in the ♂. Beneath all the wings with a yellow basal spot, the bluish irroration more distinct. Brazil. ♂ type from Leopoldina, ♀ from Bahia, in the Berlin Museum.

P. hilarina Weym. (= *biformis* Schs. ♂) (63 c). Body blackish-brown, collar and patagia with light *hilarina*. spots, in the ♂ abdomen beneath with two narrow light longitudinal stripes. Forewing partly hyaline, with a dark dentate transverse line across the centre of the cell, a similar one across the transverse vein, a dark apical and tornal area. A yellowish-white band extends from the costa to the centre of the margin, yellowish-white marginal spots. Hindwing light red, costa and distal margin black, the light area projecting on the centre of the distal margin to the border. Single dark spots in the red area may be present or absent. In the ♀ the black margins are somewhat broader. — In the form **fulva** Weym. (63 c) the red area of the hindwing is yellow. *fulva*. South Brazil.

P. hilara Weym. (= *biformis* Schs. ♀) (63 c) resembles the preceding, but the hindwing is extensively *hilara*. black at the anal margin and from the direction of the base, whilst the red colouring is only found in a large crescent round the cell-end. It may only be a form of the preceding. South Brazil. — It likewise occurs with yellow colouring on the hindwing, like *fulva* Weym.; this is **mutata** form. nov.; ♀ from Castro (Paraná) in the *mutata*. Tring Museum.

3. Costa at the base with a very much contrasting light longitudinal streak; abdomen in the ♀ uni-coloured or with a dark dorsal line. Subgenus *Sermyla* Wkr.

P. transversa Wkr. (63 f) is blackish-brown, collar and patagia spotted yellow. Abdomen in the ♀ *transversa*. above with two yellow lines, two similar lateral ones and two ventral ones. Wings black, forewing with a yellow costal streak as far as about $\frac{2}{3}$ of the costa and a yellow subapical band to the centre of the distal margin, hindwing with a yellow central spot. Beneath the base is yellow in the length of the costal streak as far as the analis. Brazil.

P. morta Schs. approximates *transversa* (63 f), the costal line and subapical line are connected, *morta*. hindwing uni-coloured blackish-brown. Abdomen blackish-brown. Brazil.

4. Abdomen in the ♀ with a dark dorsal streak. costa at the base not with a conspicuously light longitudinal line. Subgenus *Pericopis* Hbn.

P. lycaste Klug (= *iscariotes* Bsd., *cydon* Drc.) (63 e). Body blackish-brown, patagia and thoracal *lycaste*. sides with scanty yellow scales; abdomen above red with a black dorsal line, laterally with black lines, beneath brimstone-coloured, posterior margins of the segments in the centre black. Forewing blackish-brown with a diffuse hyaline transverse band extending from the tornus to the costa, bifurcating at the discal cell, the outer portion projecting between the 1st cubitus and 2nd median towards the margin. Hindwing hyaline in the ♂; costa, transverse vein, and margin black, the latter with a row of white submarginal spots, before them a brick-coloured red band being more or less extended to the apex. ♀ hindwing of an ochreous-red ground-colour, margin black with white spots, before it an irregular black line. Beneath the costa of the forewing with a red basal streak, the black markings partly covered with red-brown. — In the ♂ form **praetides** Drc. (63 f) *praetides*. the red parts in the margin of the hindwing are absent; — in **tibesis** Drc. (63 d, e) the ♂ hindwing is not whitish *tibesis*. hyaline, but red-hyaline. Mexico to Colombia. — Larva dark brown, spotted black in dorsal, lateral, and stigmatal lines between the reddish-brown tubercles. Segment 4 is lighter, 5 and 11 dark, their tubercles black; 3, 6 and 13 are somewhat darker.

P. viuda Schs. (63 d). ♀ similar to that of *lycaste*, but much larger, abdomen above ochreous-yellow *viuda*. with black posterior margins of the segments and a black dorsal line. Hindwing ochreous-yellow, the black band between the cell and margin very broad, analwards very much widened. Panama.

- P. marginalis.** All the forms of *marginalis* differ from those of *lycaste* by the broad yellow basal spot of the patagia. The transverse band of the forewing is more distinct, more hyaline, not so dusky as in the preceding.
- marginalis.* Abdomen beneath yellow, without black segmental margins. **marginalis** Wkr. (♂ = *dissimulans* Wkr.). ♂ ground-colour brown, ♀ with a black postdiscal line in the hindwing, which is hardly widened towards the anal margin, the hindwing being brick-red to ochreous. Venezuela, Colombia. — **crassifascia** subsp. nov. (63 d) is in the ♂ larger, with more blackish-brown forewings, the bands in the hindwing as well as the ground-colour of it in the ♀ more dark red, the hindwing with a black postdiscal line being very much widened towards the anal margin. South Colombia, Bolivia, Ecuador (type from the Putumayo in the Berlin Museum). — **panamensis** subsp. nov. resembles more *marginalis*, but in the ♀ the postdiscal band is narrow and short, not continued to the anal margin, mostly terminating before the 2nd cubitus; the band of the forewing is in the ♂ more whitish, not so hyaline as in the preceding races. Panama. (Type from Chiriqui in the Berlin Museum). — **magdala** Bsd. (63 f) is the smallest race. Forewing 32 (♀) or 29 (♂) mm long; in the ♂ the band of the forewing and of the hindwing is very much strewn with white scales, nor are the veins behind the cell of the hindwing dark. ♀ similar to *marginalis*, but smaller. Hindwing hyaline reddish, band as in *marginalis*. Nicaragua to Guatemala.
- lygdamis.* — **lygdamis** Drc. In the ♀ likewise similar to the type, ♀ forewing brown, the band less contrasting, distally indistinctly defined; hindwing brick-red, band similar to that in *crassifascia*. ♂ in the band of the forewing very white, the red antemarginal band of the hindwing almost as broad as in the ♀. — In the form **leda** Drc. the costal margin of the forewing is basally quite pale, all the markings are narrower. Costa Rica.
- fortis.* **P. fortis** Schs. is extremely similar to the preceding, but the forewing at the base behind the red costal dot yet with a short, thick yellow longitudinal streak on the cell. In the ♀ the veins of the hindwing are only distally to the antemarginal band black, otherwise like *lygdamis*. Costa Rica.
- zeladon.* **P. zeladon** Dyar bears a relationship to *marginalis* just like *tibesis* to *lycaste*; a remarkable fact is that also *tibesis* as well as *zeladon* is chiefly the Mexican representative of the respective species. ♂ with a red-hyaline hindwing, otherwise like *marginalis*. Separable from *tibesis* by the broad yellow basal spot of the patagia. Mexico.
- gaumeri.* **P. gaumeri** Drc. (63 c). ♂. Body as in *marginalis*, but the black dorsal line does not reach to the anal segments; anus black. Hindwing white, marginal line and ochreous spots brown. Forewing hyaline, at the costa two spots, the anterior portions of the distal margin and proximal margin brown. The ♀ being supposed to belong to it resembles Central American ♀♀ of *marginalis*, but it has no white spots in the margin of the hindwing. Mexico.
- neda.* **P. neda** Klug (= *submarginata* Wkr.) (63 f). ♀ brown, collar and patagia spotted ochreous. Abdomen above with a black dorsal line and black segmental margins, beneath yellow with a black central line. Forewing grey, feebly hyaline, $\frac{2}{3}$ of the proximal margin, a transverse band at $\frac{1}{2}$ of the costa, transverse vein and distal margin darker blackish-brown, the latter indented at the 3rd median. Sometimes there are some dark internerval stripes. Hindwing yellow varying with red-brown, veins and margin black, the latter often with yellow submarginal spots. ♂ (= *fanatica* Dogn.): abdomen above lighter, dorsal line broader, wings more extensively hyaline, forewing often without a transverse band, hindwing hyaline sulphur-coloured, margin much narrower than in the ♀, sometimes quite absent. — In the form **nubila** Wkr. of which only the ♀ is known to me, the veins of the posterior half of the hindwing are very broadly bordered with black. Brazil, Colombia.
- nubila.* **P. indecisa** Wkr. (63 g). Body blackish-brown, collar and patagia on each side with 2 yellow spots, abdomen above with 2 yellow subdorsal stripes, beneath yellow with a narrow black median line. Proximal margin of forewing as far as the analis blackish-brown, of the same colour a transverse band at $\frac{2}{5}$ of the costa, another broader one across the cell-end to the tornus and with a blackish-brown apical part. Subapical band yellowish hyaline, the other hyaline portions dusted with brownish. Hindwing varying from yellow to ochreous. Costa, transverse vein, and distal margin as far as the cell blackish-brown, the distal margin with yellowish or white submarginal spots and in front of it with a ferruginous red band being interrupted between the 2nd cubitus and 3rd median branch. Brazil.
- indecisa.* **P. aorsa** Bsd. (= *lucetia* Btlr., *umbra* Drc.) (64 a). Body as in *indecisa*, abdomen with a very broad black median line beneath. Forewing as in *indecisa*, but shorter, hindwing varying from ochreous to pinkish-orange, with a narrow, black margin dotted bluish-white, a black costa and veins, distally to the cell a black postdiscal line being pointedly extended on the veins, at the anal margin extended to the base. S. Salvador, Honduras, Guatemala.
- aorsa.* **P. recta** sp. n. (63 g) is very much like *aorsa*; but whilst in the latter the dorsal line of the abdomen is on each segment expanded at the posterior margin, it runs here uniformly. Wings on the whole lighter, the postdiscal band of the hindwing is much narrower, not so pointedly extended. The discal and subapical bands of the forewing are more broadly separated, not connected. Panama, Colombia. ♀ type from the Canca in the Berlin Museum.
- recta.* **P. joiceyi** Dgn. (♂ = *talboti* Dgn.) (63 g). In the forewing the dark ground-colour is confined to the costa, apex, distal margin, proximal margin as far as before the analis, a black thin line from $\frac{2}{5}$ of the costa to the proximal margin, another one from $\frac{3}{4}$ of the costa to the distal margin; the latter line is broader, it crosses the transverse vein and is expanded at the distal margin. The black places are covered with reddish-brown, the hyaline ones in the ♂ almost transparent, in the ♀ dusted with brownish. Hindwing red-brown, in the ♂ very hyaline, with black veins, in the ♀ a broad black transverse vein and a black margin containing white

submarginal spots and before them ferruginous spots. Body blackish-brown, patagia basally broad yellow, thorax with 2 or 3 white spots, abdomen at the base, particularly in the ♂ white-haired, with a black dorsal line and black lateral lines; the ochreous colour warms behind into greenish. Anal tuft ochreous-yellow. Ventral side quite brimstone-coloured. Colombia.

P. molesta *sp. n.* (63 g). ♂. Body blackish-brown, collar and patagia spotted yellow, thorax behind *molesta*. and anterior half of abdomen red-brown, the posterior half greenish, dorsal and lateral lines of the latter black, underside quite brimstone-coloured, anal tuft ochreous-yellow. Forewing as in *P. recta*, but with comparatively large white triangular antemarginal spots. Hindwing reddish-yellow, veins of the same colour, margin black, narrow, with large white triangular spots. Under surface similar to the upper, proximal margin of forewing red-brown, hindwing somewhat dusted dark. Colombia. ♂ type from Popayan in the Berlin Museum.

P. anadema *Drc.* was not before me. Very much like *molesta* (63 g), larger (expanse of the ♂ 65 mm), *anadema*. hindwing with black veins, the ♀ forewing brownish-yellow, with a broad, broken, yellow transverse band; hindwing orange, distal margin black with indistinct white spots. Colombia.

P. bivittata *Wkr.* (= *disjuncta* *Wkr.*) (64 a). In the habitus recalling *P. aorsa* (64 a) and *recta* (63 g), *bivittata*. wings more longish, underside of abdomen without the black median line. Discal band and subapical band of forewing broad, yellow, both nearing each other, rarely narrow. Hindwing red-brown, with a black margin dotted bluish-white, and a black transverse band before it. The veins between both, and the transverse vein black. Postdiscal band and white submarginal spots may disappear. Venezuela, Panama.

P. daphne *Drc.* (64 a) is one of the rarest species. Similar to *P. bivittata*, the yellowish-hyaline transverse *daphne*. bands of the forewing white, of the same colour distinct submarginal dots on both wings and a spot behind the cell on the hindwing beneath. Panama.

P. eurocilia *Cr.* (= *zerbina* *Stoll.*) (64 a). Forewing blackish-brown, in the basal half more or less *eurocilia*. lighter, with a narrow brimstone-coloured discal band and subapical band which are so close together that they are confluent before and behind the cell and thus enclose the blackish-brown spot on the transverse vein. The posterior band may be shortened. White submarginal spots absent or present. Hindwing as in *bivittata*, the extent of the black markings very variable. Body also like in *bivittata*. — In *obscurata* *form. nov.* the whole *obscurata*. basal part of the forewing is fused with the bands which are here densely dusted with brownish, there only remains a blackish spot in the centre of the cell; hindwing black, only the costa, a posteriorly narrowed submarginal band from the costa to about $\frac{1}{2}$ of the distal margin, the upper part of the cell, distally and basally prolonged, are red-brown (♀ from the Chanchamayo in the Berlin Museum). — *melaina* *form. nov.* is quite *melaina*. blackish, only the bands in the forewing brimstone-coloured, the red-brown markings marked with a violettish grey (♀ from Tachira, Venezuela, in the Tring Museum). Colombia, Amazons, Guiana, Ecuador, Peru, Bolivia.

P. irene *Drc.* (64 a). Forewing blackish-brown, at the base more or less lighter, with but one yellow *irene*. transverse band in the centre of the wing. Hindwing and body as in *eurocilia* *Cr.* The Brazilian race has a length of the forewing of about 33 mm. — In the subsp. *staudingeri* *Drc.* the forewing is at least 37 mm long, *staudingeri*. and it has a somewhat narrower band of the forewing. — Of the latter there exists a form with a milky-white band of the forewing, and a similar oblong spot crossed by the red transverse vein in the distal half of the cell in the hindwing: *splendidissima* *form. nov.* (64 b) (♀ type from San Domingo, Carayaba in the Tring Museum). *splendidissima*.

P. unifascia *sp. n.* (64 b). Body blackish-brown, collar and patagia on each side with two yellow *unifascia*. spots. Abdomen above yellow, dorsal line and lateral line black. Ventrums light yellow; anal segment black with an ochreous-yellow apex. Forewing blackish-brown, band as in *staudingeri*, hindwing yellow, costal margin and transverse vein and a broad distal margin black; the latter at the cubitus almost 1 cm broad, anteriorly narrowed, all the wings with above indistinct, beneath distinct white submarginal spots. Beneath as above, bases of wings and costal stripe at the base of the hindwing brown. Paraguay. ♀ type from Sapucay in the Tring Museum.

P. amphissa *Geyer* (64 b). Body and forewing as in *indecisa* *Wkr.*, on the forewing above the two *amphissa*. transverse bands are connected behind the cell. Hindwing ochreous-yellow, margin and veins broad black, the margin with yellow submarginal dots. — In *subguttata* *Wkr.* the ground-colour of the hindwing is not *subguttata*. brownish-yellow, but brimstone-coloured. ♂ (described as *Coborisa vestalis* *Bltr.*) body whitish, with brown markings on the thorax; palpi, abdominal end and basal spot of forewing ochreous-yellow, dorsal line of abdomen black. Wings whitish hyaline, with thinly blackish-grey markings: in the forewing the margins, except at the tornus, one transverse band each across the centre of the cell and the transverse vein, in the hindwing the costa, distal margin and veins. Sometimes the markings, except the veins, are not grey, but densely white. Brazil. — The ♀ copies certain species of *Actinote*.

P. forbesi *Drc.* (64 b). Forewing with a red basal dot and the usual hyaline markings, which are *forbesi*. similarly shaped as in *joiceyi* (63 g). Hindwing yellow, costa, transverse vein, and distal margin broad black, the latter sometimes with traces of red spots. Veins black. Body varying from yellow to greenish, dorsal line and lateral line black, abdomen brimstone-coloured with a black median stripe. South Brazil.

- picta*. **P. picta** Guér. (= *capella* Drc.) (64 c) resembles *forbesi*, in the forewing the subapical band is like in *indecis*a, slender and straight, almost reaching to the distal margin. Hindwing in contrast with *forbesi* with white or yellowish small submarginal spots. Brazil.
- puhites*. **P. puhites** Drc. (described as *Hyalurga*). Head and collar pale yellow, thorax and abdomen brown, with a central bluish-white line; abdomen beneath dusky white, anus orange. Wings greyish hyaline, the margins of the forewing black, the broadest at the apex, with a black transverse band to the tornus, enclosing an oval, white, black-veined spot. Hindwing as in the ♂ of *amphissa* (64 b), veins broad black. Although the species was not before me, I do not doubt that it belongs to the *Pericopis* being similar to *Coborisa*. Upper Amazon River.
- fulgorata*. **P. fulgorata** Btlr. was not before me. Forewing in the marking similar to *P. (Thebrone) hilarina* Weym. (63 c), hindwing yellow, veins black, transverse vein with a broad black band, margin with a dentate black band. Body black, thorax with yellow spots, abdomen yellowish, at the end greenish, with a black dorsal and lateral line, beneath yellow. Pará.
- fenestrata*. **P. fenestrata** Wkr. (64 c). ♂. Still more thinly scaled than *amphissa*-♂ (*vestalis*), distal margin of forewing somewhat convex (in *vestalis* straight); blackish are in the forewing at most the transverse band, costa, veins, and minute spots at the margin, in the hindwing some spots on the veins at the margin at most. Otherwise like *amphissa*-♂. Mexico.
- grassator*. **P. grassator** sp. n. (64 c). In the habitus somewhat like *P. thyridina* Btlr. (62 d), in both sexes the body is black, thorax and patagia mostly dotted, abdomen above greenish, beneath brimstone-coloured, dorsal line and lateral line black. Wings longer and more extended than in *thyridina*, the hyaline basal part of the forewing is more broadly separated, in the hindwing the transverse vein is broader black, the posterior margin of the cell black. Colombia to Peru. ♂♀ types in the Berlin Museum from Puerto S. Rosa — The species, in its exterior, recalls species of *Thyridia*.
- sacrifica*. **P. sacrifica** Hbn. (= *crucifera* Perty) (64 c). Body blackish-brown, half of the collar, base of patagia, two subdorsal and two smaller lateral rows of spots yellow. Forewing blackish-brown, basally with 2 red dots, with a whitish hyaline marking resembling a \rightarrow . Hindwing with a brown margin, before it a row of white spots before which there is a red, black-edged band; the rest of the wing in the ♂ whitish hyaline, in the ♀ brown with some yellowish-white spots distally to the cell. In the whole of South America as far as Argentina. — The larva lives on Compositae (*Senecio balansae*, and a species of *Eupatorium*), it is greyish-yellow, with a narrow dorsal line, a broader subdorsal line, 3 narrow lateral lines, a broader subventral line and a narrow ventral line, all of which are dull purple red. Tubercles ochreous-yellow, one on the 2nd, two on the 4th, two on the 10th and 1 on the 13th abdominal segments blackish-purple. Pupa blackish-brown, with a violet lustre, with small ochreous-yellow bristles.
- dissimulata*. **P. dissimulata** Wkr. (= *madana* Drc.) (64 d). Body blackish-brown, head, collar, patagia and thorax with bluish-white dots. Abdomen with two bluish-grey subdorsal lines, otherwise black, beneath yellow. Wings blackish-brown, the lighter markings whitish hyaline; in the forewing are hyaline: a basal triangle between the costal margin and proximal margin, a broad discal band as far as the tornus, a subapical band terminating before the centre of the distal margin, the two latter bands being above, but not beneath, connected by a hyaline spot. Sometimes there are white submarginal spots. Hindwing whitish hyaline, costa, margin, and the broad transverse vein and the veins are black, the margin with white submarginal spots. The black parts of both wings are more or less dusted with red-brown. Venezuela, Colombia, Ecuador.
- mosera*. **P. mosera** Drc. is perhaps the ♂ of *dissimulata*. On the whole smaller, the collar with yellow instead of white spots. The subapical band of the forewing almost reaches to the distal margin. Colombia, Peru.
- moseroides*. **P. moseroides** sp. n. is in every way a true image of *mosera*, but on both wings the whitish-hyaline places are brownish-yellow hyaline, the shade of the colouring like in *joiceyi* (63 g), abdomen above greenish-yellow with a black dorsal line. The transverse vein of the hindwing is less broad black. Forewing with the same very convex distal margin as in *mosera*. Both are perhaps seasonal dimorphisms of one species. Bolivia. ♂ type from the Rio Songo in the Berlin Museum.
- arema*. **P. arema** Bsd. (64 d). This species, and those allied to it, strongly recall the species of *Thebrone*, but the ♂ and ♀ are similarly coloured and marked. Forewing blackish-brown with a hyaline triangular spot at the base, a similar discal and subapical band, both being behind the cell connected. Hindwing whitish hyaline, distally scaled somewhat yellow, costa and distal margin broad black with a row of white submarginal spots. Body brown, patagia at the base yellow. Abdomen with two subdorsal rows of yellow spots, a red anal tuft, with two ventral rows of yellow spots. Nicaragua, Venezuela.
- imitata*. **P. imitata** Drc. (64 d) resembles *arema*. Abdomen with subdorsal spots varying from greenish to bluish-grey, beneath only with one row of spots in the forewing. The hyaline places are more brownish, the dark band through the centre of the cell broader, hindwing with a broader black distal margin (particularly at the anal angle), the discal area uniformly hyaline greenish-yellow. Bolivia, Peru.

P. pagasa Dgn. ♂ similar to that of *palmeri*. Hindwing of a pure white, with a broad black costal and distal margin as well as transverse vein. There are, however, no white and red spots at the margin. Brazil: São Paulo.

P. titan Drc. (♀) resembles *imitata* (64 d), collar with white spots which are yellow in *imitata*; abdomen beneath yellow. Forewing as in *imitata*. Ground-colour of hindwing hyaline white, otherwise like the preceding. Peru: Chanchamayo. This and the following *palmeri* remained unknown to me. Expanse of wings: 45 mm.

P. palmeri Drc. Body black, patagia in the ♂ spotted yellow, abdomen with yellow subdorsal spots, beneath yellow, at the end red. Forewing with a red basal spot, a yellow streak on the proximal margin and hyaline markings as in the preceding, the latter, however, edged with yellow; hindwing white (♂) or yellowish (♀), with a broad black distal margin in which there are white submarginal spots and before which red spots. Veins black, transverse vein broad black, costal margin red. Expanse of wings: ♂ 70, ♀ 90 mm. West Colombia, East Peru.

P. practides Drc. (63 e). Body black, patagia spotted yellow, abdomen above with subdorsal rows of white spots, beneath with two rows of yellow spots. Forewing blackish-brown, proximal margin with an ochreous-yellow margin. Across the cell-end extends a grey hyaline band to the proximal margin, enclosing the brown cell-end spot; white submarginal spots. Hindwing whitish hyaline, clouded with blackish, veins black, transverse vein broad-black, costal and distal margins ochreous-yellow, on both sides narrowly edged with black, white marginal spots. Forewing beneath more extensively ochreous-yellow. ♀ with more indistinct markings, abdomen with white bands. Colombia.

P. luctuosa Dgn. is similar to the preceding, patagial and abdominal spots white. The projection of the hyaline band towards the margin is very short. Hindwing quite black, beneath with a darker discal spot. Peru.

P. hodeva Drc. is unknown to me. ♀ body black, collar spotted yellow, patagia edged with red-brown. Abdomen above red-brown, with a black dorsal line and black lateral lines. Underside pale yellow, anus bluish-grey. Apical third of forewing black, cell brownish-yellow, clouded with brown, the proximal margin the same; veins black. At the cell-end a yellow line. Hindwing black, yellowish-brown at the apex and half the distal margin. Under surface more contrasting, a distinct black spot on the centre of the cell of the forewing. Expanse of wings: 90 mm. Peru.

P. brunnea Drc. Likewise unknown to me, allied to *hodeva*; body black, collar spotted yellow. Abdomen black, above with yellow subdorsal spots, beneath dingy yellow. Forewing basally dark brown, distal half light brown, apex and distal margin blackish-brown. Hindwing blackish-brown with an indistinct red-brown submarginal line. Forewing beneath with a red-brown transverse band near the apex, a pale brown cell-end spot and three similar streaks at the tornus. Hindwing with a red-brown costal margin, a large pale brown spot distally to the cell, the submarginal line more distinct. Expanse of wings: 35 mm. East Ecuador.

P. rhea Drc. is also unknown to me. Body black, collar spotted yellow, thorax yellowish-brown like the abdomen, with a black dorsal line and black lateral lines, beneath pale yellow. Forewing with a brownish-black apical third, the other two thirds dark orange-yellow, with black veins, a black transverse vein and band from the costa to the 2nd cubitus. Hindwing orange, distal margin and a transverse band before it black. Expanse of wings: 95 mm. Peru: Rio Pachitea.

P. practidoides sp. n. (64 d). Body blackish-brown, patagia and bases of wings with a red spot. Abdomen above with 2 rows of greenish-yellow spots, beneath yellow with black segmental margins, behind narrow red. Forewing brown, with yellowish and olive-coloured tints, with a lighter discal and subapical band, the latter as in *lycaste* and others projecting towards the margin. Hindwing pale yellow, margin black, extending to the cell, with red submarginal crescents, veins black, transverse vein broad black, costa reddish. Colombia. ♀ type from the Upper Rio Negro. (Coll. FASSL.) (It may be the ♀ of *practides*?)

P. guapa Schs. ♀. Unknown to me, in the habitus it is said to resemble *P. (Chetone) ithomia* (62 a). Body black, head and thorax with white spots. Abdomen red-brown with a black dorsal and lateral line, beneath yellowish-white, anal hairs red-brown. Forewing blackish-brown, with white marginal spots, a row of indistinct pale spots from the costa across the cell-end, and two subterminal spots below the 2nd cubitus. Beyond the cell there are 5 whitish hyaline spots from the costa to the 1st cubitus. Hindwing reddish-brown, veins and extreme base black; costa narrow black, distal margin broad black, the latter with yellowish-white marginal spots. Hindwing beneath with a red stripe or dot at the base of the costa, the black distal margin is reduced to some black dusting. Expanse: 66 mm. Costa Rica.

P. humeralis Wkr. (64 d, e) differs from *guapa* as follows: base of patagia, and collar with yellow spots, abdomen beneath with black posterior margins of the segments, forewing with a more distinct light costal spot before the transverse vein, without marginal spots; hindwing with no black veins, distal margin without marginal spots, forewing beneath more reddish-yellow, particularly at the proximal margin. The ♂ has on the mesothorax two large yellow spots, the forewing is darker, with a red and yellow basal streak, the fresh specimen irrorated with greenish on the dark places. Hindwing otherwise like in the ♀ of *guapa*, anal margin black-haired. Forewing beneath almost black, costa of both wings basally red. Mexico.

perplexa. **P. perplexa** Schs. ♂. Body similar to *guapa* Schs. Abdomen above dark grey with a black dorsal and lateral line, beneath whitish. Forewing blackish with a red costal streak at the base, grey hyaline streaks in and below the cell, a black longitudinal line in the cell, a broad, grey-dusted light cell-end spot, four whitish hyaline subapical spots and white marginal spots. Hindwing whitish hyaline, veins, costal and distal margins black, the latter with white submarginal spots, a broad black transverse vein and a blackish proximal margin. Expanse: 59 mm. Costa Rica.

montezuma. **P. montezuma** Schs. (64 f). ♀ body as in *humeralis* (64 d, e). Abdomen above grey. Forewing likewise as in *humeralis*, hindwing yellowish-white with a black, yellow-spotted distal margin which is broader than in *humeralis*, transverse vein broad black. Expanse: 85 mm. Mexico.

rorata. **P. rorata** Wkr. I was unable to place this species. ♀ dark red-brown, abdomen spotted white, at the end ochreous-yellow, laterally with a white subdorsal stripe, beneath white. Forewing spotted white with short, broad, slanting white stripes across the transverse vein. Hindwing yellow with a broad dark red-brown margin, which contains beneath white submarginal spots. Length of wings: 45 mm. Colombia.

17. Genus: **Dysschema** (*Anthomyza* Swns.)

This genus, on the whole, agrees with *Pericopis*, but the ♀ antennal pinnae are longer, at least as long as the diameter of the shaft, and the 2nd radial in the forewing is mostly separate. The 3rd palpal joint is short, less than $\frac{1}{2}$ of the second. They are a striking imitation of the *Danaidids*, and are very similar to species of *Thyridia* and *Ituna*.

tiresias. **D. tiresias** Cr. (= *swainsoni* Drc.) (64 e). Body black, head and thorax dotted white, abdomen above blackish-brown, two fine lateral lines yellow, beneath yellow. Forewing black, basally with some white dots and a yellow inner-marginal spot, above the centre of the cell with a yellow transverse band which terminates on the axillaris before the tornus, a yellow subapical band between the 1st cubitus and 5th radial branch; in the yellow bands the veins are black. A more or less complete row of white antemarginal spots. Hindwing yellow, slightly hyaline, veins black, costal and distal margins broad black, the latter with white submarginal spots; transverse vein hardly broader black than the other veins. — According to a drawing by Dr. SEITZ from life, the adult larva is black, with dense, tufted hairing of hard prickles on tubercles, somewhat like in the larvae of *Ecpantheria*, the 3rd, 6th and 11th rings being light lemon-coloured. The lustrous brown pupa lies in a very thin web, and yielded the imago after 3 weeks.

heliconides. **D. heliconides** Swns. (64 e) agrees with *tiresias*, but all the yellow markings are here quite hyaline, pale yellowish. The transverse vein of the hindwing is broad black, behind connected with the black, here projecting distal margin. — **obsoleta** form. nov. (♀ type from Surinam) is without this band of the transverse vein and the projection of the distal margin. Guiana, Amazons, Colombia, Peru.

The following species remained unknown to me, for which reason I cannot guarantee their being correctly placed in this genus.

brotes. **D. brotes** Drc. Head and thorax according to the description quite black, the white basal spots and the yellow inner-marginal spot are absent; hindwing pale yellow, with black veins and a black broad margin exhibiting only 1 submarginal spot at the apex and four next to the anal angle. British Guiana.

buckleyi. **D. buckleyi** Drc. Body as in *heliconides* (64 e), forewing brownish hyaline, base, a transverse band across the cell-end, apex, costal margin, distal margin, and partly also the proximal margin black, costa basally with white dots, a yellowish-brown spot on the proximal margin, the white submarginal spots like in the preceding. Hindwing brownish hyaline, with a black margin containing white submarginal spots, and black veins; ♀ paler. Ecuador.

18. Genus: **Are** Wkr.

The generic marks agree with those of the following genus, but the distance between the 1st and 2nd radials is twice as long as that between the latter and the 3rd to 5th.

marginata. **A. marginata** Drury (64 f). Body blackish-brown, collar, patagia, and costa of forewing as far as the centre wood-coloured. Abdomen above with bluish-grey subdorsal spots. Forewing blackish-brown, with a reddish, duskily dusted transverse band across the cell-end, enclosing a costal spot on the transverse vein of the ground-colour; in the ♀ mostly only this light-edged spot is left. Hindwing blackish-brown, milky-white spots near the base in and behind the cell, distally to it a larger and smaller antemarginal spot. Beneath all the markings are very faint, costa of forewing with an ochreous-yellow stripe, that of the hindwing with such a spot. Jamaica.

mumma. **A. mumma** Cr. (64 e). Forewing blackish-brown, its centre wood-coloured, with irregularly inserted dark places, which are here and there silvery blue like an antemarginal waved line. Hindwing black, with a white iridescent central spot, fringes at the apex white. Smaller than the preceding species. Surinam.

19. Genus: **Phaloë** Guér.

It differs little from *Dysschema* Hbn., the 3rd palpal joint, however, is about a half of the second or longer, in the forewing the distance from the 1st to 2nd radial is about the same as that from the 2nd to the 3rd to 5th, or shorter.

Ph. cruenta Hbn. (= *lorzae* Bsd.) (64 e, f). Body blackish-brown, head and thorax with white *cruenta*. dots, abdomen above brown, with 2 fine yellow lateral lines, beneath dingy white, apex red. Forewing brown, basally at the costa some red spots or streaks, behind the cell a not unfrequently absent yellow spot, a band of yellow spots from the centre of the costa to the tornus, often shortened, a yellow or hyaline subapical band. Hindwing yellow, with a black margin and white submarginal spots, in the ♀ the veins are black, particularly the transverse vein and the distal branches of the veins. The markings of the ♂ are generally more hyaline than those of the ♀. Guatemala to Argentina. Larva on *Eupatorium laeve*, dingy grey with interrupted, narrow purple longitudinal lines. Tubercles ochreous-yellow, but blackish-violet are on each side: on the 2nd (thoracal) segment two (behind them a red spot), on the 4th to 6th three, on the 8th to 10th and the 12th also three. Pupa blackish-brown.

The following 3 species remained unknown to me; they may partly belong to *Pseudophaloë*.

Ph. pyste Drc. resembles *cruenta* (64 e, f). Forewing without any red dots, a broad yellow band extends *pyste*. on the forewing from the base on the proximal margin almost to the tornus, a submarginal row of white spots. Both wings beneath at the base of the costa chrome-yellow. Ecuador.

Ph. ignita Btlr. entirely agrees with *cruenta* (64 e, f), but on the forewing there are also at the apex *ignita*. white submarginal spots which I could never ascertain in *cruenta*, not even in very large series. Tapajos.

Ph. vespertilio Dgn. Body black; patagia behind yellow. Forewing lemon-coloured, with black markings: *vespertilio*. one spot occupying more than half of the costal margin, extending down to the posterior edge of the cell from where it despatches a pointed branch to the 1st cubitus and to the 3rd median, and entering at the proximal margin a broad black band which goes almost to the base; behind the cell there remains an oblong yellow spot. The last quarter of the costa and the margin likewise black. Hindwing orange with a black apex and distal margin. Colombia. This species presumably hardly belongs to *Phaloë*.

Separated from *Phaloë* by the straight, scarcely convex margin of the forewing. (Subgenus: *Sphaeromachia* Grt.).

Ph. cubana H.-Schäff. (64 f). Body blackish-brown, thorax in front dotted yellow or white, behind *cubana*. like the abdomen yellow (♂) or white (♀). Wings yellow (♂) or white (♀), a black band on the forewing extends at first along the costa, filled up with red spots, at about $\frac{2}{3}$ bent to the posterior margin, terminating shortly before the tornus. The distal half of the wing is black, with two rows of hyaline spots, and 1 or several yellow (white) submarginal spots. Proximal margin in the ♂ like the abdominal apex black. Hindwing with a black distal margin and in the ♂ besides black costal margin, submarginal spots in the ♀ numerous, in the ♂ mostly only one. Mexico, Yucatan, Honduras, West Indies.

20. Genus: **Ctenuchidia** Grt.

Small, rather similar species with a Syntomid-like habitus. From all the *Pericopinae* with 1 pair of spurs on the hind tibiae and a separate 2nd radial in the forewing, in which the 5th radial rises before the 3rd, it is distinguished by the long -forked, sometimes fused 3rd median and 1st cubitus of the hindwing. The species mostly exhibit blackish-brown forewings with 2 or 3 hyaline dots behind the centre of the cell, and an undulate subapical band of such dots. Sometimes also some dots between the cell and proximal margin. Hindwing and the centres of all the wings beneath black with an intense blue lustre. Before the apex of the hindwing there may be 1 or 2 hyaline dots.

Ct. virgo H.-Schäff. (65 a). Abdomen black, above lustrous blue, the last three rings yellow, with a *virgo*. black dorsal line and anus. This yellow colouring coheres with two lateral stripes of the abdomen, which are basally, rarely entirely red. Abdomen beneath with 2 rows of white spots. Forewing with a red costal spot at the base. Cuba. — The pupa (original example of HERRICH-SCHAEFFER) deviates from those of all the *Pericopinae* known to such an extent that it is almost questionable whether it belongs hereto. Pupa golden brown with minute purple spots, in front with two multicuspitated black conical protuberances, below them another similar one, but with only one point. These small cones probably serve the pupa for extricating itself out of the web.

Ct. fulvibasis sp. n. The spots at the base of the forewing are ochreous-yellow, abdomen above quite *fulvibasis*. black, only with yellow lateral stripes, beneath the white spots are more streak-shaped, otherwise like *virgo*. Jamaica. ♂ type in the Berlin Museum.

- interrupta*. **Ct. interrupta** *sp. n.* Basal spot of the forewing ochreous-yellow, abdomen like in the preceding, but the yellow lateral stripes in the centre very much narrowed or interrupted. Hindwing with two hyaline subapical spots, which equal the very large other subapical spots of the forewing in size. Dominica (Antilles). ♂ type in the Tring Museum. Expanse of wings: 25 mm.
- subcyanea*. **Ct. subcyanea** *Wkr.* Abdomen with red lateral stripes, basal spot of the forewing red. Length of forewing: 20 mm. Patria unknown. — This species and the two following were not before me.
- agrius*. **Ct. agrius** *F.* Abdomen with yellow lateral stripes, forewing without the red basal spot. Surinam.
- butus*. **Ct. butus** *F.* Body beneath and the whole of the abdomen yellow, anus blackish. Wings uni-coloured. South America.

21. Genus: **Phaloësia** *Wkr.*

From all the genera hitherto dealt with exhibiting 1 spur on the hind tibiae, it is distinguished by the 3rd radial in the forewing rising before the 5th.

- saucia*. **Ph. saucia** *Wkr.* (= *chalybea* *Btlr.*, *fulvicollis* *Btlr.*, *venezuelae* *Btlr.*, *gentilis* *Bsd.*) (65 a). Body black, metallic; collar, lateral lines of abdomen, and lateral spot of thorax red or ochreous-yellow. Abdomen beneath sometimes with 2 rows of white spots. Also the base of the patagia is often yellow or red. Wings blackish-brown, with a violet reflection, forewing with a red costal streak at the base, behind it a similar spot a little behind the costa. In the centre of the cell a row of yellowish-white spots from the costa to the posterior edge of the cell at most, a similar one of five spots before the apex. Colour and shape of markings variable. Hindwing more dark blue, with white fringes. The marks of distinction, stated by BUTLER, are merely individual differences. — Larva: head blackish-blue, body dark ochreous, with bluish-black tubercles forming transverse bands, double black streaks on the segmental indentations and similar small irregular dots, a continuous subventral stripe. Hairs black, partly white on the subdorsal tubercles of segments 3 and 4 and on tubercle 3 on segment 12. Pupa in an open yellow network, light brown with numerous bluish-black dots and streaks on the wing-sheaths. Mexico to Venezuela.
- rubriplaga*. **Ph. rubriplaga** *Dgn.* remained unknown to me, it probably does not belong hereto. Wings of a deep blackish blue, lustrous, with four longish red spots, three of which are at the base, the fourth between the 5th radial and 1st median somewhat distally to the cell. Fringes and body bluish-black. Expanse of wings: 40 mm. Peru.

22. Genus: **Hyalurga** *Hbn.* (incl. *Lauron*, *Laurona* *Wkr.*). (*Gyara* *Wkr.*, *Cletorna* *Bsd.*)

Hind tibiae with 1 pair of spurs, in the forewing the radials 2 to 5 forked, in the hindwing the 3rd median and 1st cubitus not forked, in the forewing the 2nd radial rising before the 5th, in the hindwing the distance from the 3rd median branch to the 1st cubitus is less than double the distance of the 2nd median branch from the 3rd. — The smaller and darker species of *Hyalurga*, which were described as *Lauron*, strikingly look like certain Diopids, but they are easily discernible by the veins.

- fenestra*. **H. fenestra** *L.* (= *fenestriger* *Hbn.*, *egeon* *Cr.*) (65 a). Head and thorax black, collar with 2, thorax with 6 white spots. Patagia ochreous-yellow, often edged with blackish-brown. Abdomen above ochreous-yellow, the first and last segment white, with a black dorsal line and black subdorsal lines, the lateral lines and ventrum being white. Wings whitish hyaline, all the margins of the forewing varying from ochreous to reddish yellow, on both sides narrowly or more broadly edged with black; a similar transverse band extends across the transverse vein to the tornus where it bends towards the base. Veins blackish-brown. Hindwing with white veins and a black, more or less white-filled apex and distal margin. The transverse band is rarely quite black: — **supposita** *form. nov.* (♀ from Ucayali in the Berlin Museum), so that the species then resembles *sixola* *Schs.* (65 b), distinguished by the differently coloured abdomen and the broader band of the hindwing. — The form **amazonica** *Btlr.* has deeper reddish-yellow margins which are more broadly edged with black, and the distal margin of the hindwing only shows traces of the white filling. The form occurs with transitions among the typical form. South America to South Brazil and Peru.
- dorsilinea*. **H. dorsilinea** *sp. n.* (65 a). Head and thorax black, head and collar with white spots, patagia red-brown, edged with blackish. Thorax behind with a large red-brown dorsal spot before which and at the sides of which there are white spots. Abdomen white, with a red-brown, black-edged dorsal line, a similar subdorsal line and lateral line. Forewing similar to *fenestra*, but the transverse band only black, in the centre strangulated or interrupted. The black inner borders of the red-brown marginal line are broader. Hindwing in the black marginal area with a red-brown line, before the apex a black subapical band connecting the costal-marginal and distal-marginal bands, the part of the hyaline area, which is thereby cut off, is very small, 2 mm long, 1 mm at most broad. Veins also in the hindwing blackish-brown. ♀ type from Cumbase in the Berlin Museum (GARLEPP).

H. cinctella *Strd.* is quite similar to the preceding. The transverse band of the forewing is not interrupted or strangulated, the subapical band of the hindwing placed nearer to the cell, almost touching it, broader; the cut off hyaline spot is therefore larger. Sarayaku, Ecuador.

H. whiteleyi *Drc.* was not before me. Abdomen above brownish-yellow, sides and under surface white, *whiteleyi*. with black lateral lines. Forewing whitish hyaline, costa to the centre dark yellow, then grey, apex and distal margin yellow, proximally bordered with black, distally with white. Fringes black. Transverse line narrowly black extending towards the distal margin, veins dark. Hindwing hyaline white with a yellow distal margin as in *orthotaenia* (65 b). Expanse of wings: 50 mm. Peru, Ecuador.

H. uria *Btlr.* (65 a). Body as in *fenestra*, only in the abdomen first and last joint not white. Forewing *uria*. likewise similar to *fenestra*, transverse band only black, in the centre narrower. Hindwing with a red-brown, black-edged distal margin and black costa. All the veins black. Brazil.

H. urioides *Schs.* (65 b) resembles *uria*, but the thorax and abdomen are white with a narrow black *urioides*. dorsal line, abdomen besides with broad black subdorsal stripes; patagia red-brown, head and collar black, spotted white. The transverse band of the forewing is composed of a detached spot on the transverse vein, from which a thin line extends to the distal margin, behind the 1st cubitus bending round to the tornus and ending where the distal-marginal band meets the hind-marginal band. The red band in the hindwing is narrowed, its veins and costa are white. Panama, Venezuela.

H. noguei *Dogn.* (65 b) is quite similar to *urioides*, the collar with two white spots above each other, *noguei*. forewing without a black spot on the transverse vein, only with a thin transverse line showing towards the tornus, bending round only behind the 2nd cubitus and ending farther proximally than in *urioides*. Veins of hindwing white. Peru, Bolivia.

H. grandis *Drc.* is similar to *noguei*, abdomen above brownish-yellow with a black dorsal line and *grandis*. greyish-black lateral lines. Forewing with a black spot of the cell-end, hindwing with an ochreous marginal band extending farther anteriorly, and black veins. Peru. (Was not at hand.)

H. sixola *Schs.* (65 b). Body as in *fenestra* (65 a), forewing also similar, but the transverse band is quite *sixola*. black and very thin. Margin of hindwing only blackish-brown, 1 mm broad. Colombia, Venezuela.

H. mysis *Erichs.* (65 c) is similar to *sixola*, the dorsal and subdorsal lines are in both narrower than *mysis*. in *fenestra*. Forewing as in *sixola*, but the red-brown colouring of the anal margin only extends to the centre of the distal margin, so that its anterior half is white. Hindwing all white, without the black margin. British Guiana.

H. modesta *Mschlr.* (65 b). Body coloured as in *fenestra*, wings as in *uria*, but the transverse band *modesta*. of the forewing uniformly narrow, strongly bent, far distally from the transverse vein, anal margin only basally or with traces of red-brown, in the hindwing at the margin only the fringes are blackish-brown. In the ♀ the hyaline parts are greyish. Colombia, Guiana.

H. orthotaenia *sp. n.* (65 b) is similar to *modesta*, but the transverse line of the forewing is quite *orthotaenia*. straight, the whitish subapical spot is without darker veins, the reddish-yellow distal band of the hindwing is distally bordered with white. Costa basally as far as one fourth bordered with reddish-yellow, then only again distally to the transverse line reddish-yellow. Upper Amazon River, ♂ type from São Paulo in the Berlin Museum.

H. fenestrata *Wkr.* (65 c). Body white with a black dorsal line, collar and patagia partly ochreous. *fenestrata*. Wings hyaline milky-white, the forewing with dark veins, a longitudinal stripe at the costa varying from wood-coloured to ochreous, rarely a similar one at the tornus, sometimes indistinct traces of a blackish transverse line. Brazil.

H. clara *Btlr.* (65 c). Similar to *fenestrata*, wings shorter and broader, all the veins darker, forewing *clara*. at the base with an ochreous spot, costal stripe mostly only densely greyish-white. Abdomen with 3 narrow black dorsal lines. Brazil.

H. pura *Btlr.* remained unknown to me. ♂ smaller than *fenestrata* (65 c), whiter, with a comparatively *pura*. broader yellow costal margin of the forewing; base of „media and submedia“ not black. Hind margin never yellow, no trace of a transverse line. Brazil.

H. subnormalis *Dyar* (65 d) is similar to *clara* *Btlr.* (65 c), but smaller, ♂♀ with a more darkened costal *subnormalis*. stripe, which is invariably ochreous at the base and end, always with a blackish spot distally to the cell and a similar one at the margin between the 1st and 2nd cubitus. From Panama to Brazil.

H. alboritrea *Wkr.* (65 c). Body as in *subnormalis*, wings quite greyish hyaline, basal spot of forewing *alboritrea*. and sometimes part of the costa ochreous, whitish hyaline remain: a subapical band of the forewing and the discal cell of the hindwing, and sometimes the distal margins of the wings. Panama to Brazil and Peru.

H. caralis *Drc.* Head and thorax black with white spots. Abdomen above brownish-black with broad *caralis*. subdorsal and lateral lines, beneath dingy white. Forewing whitish hyaline, the margins broadly black, at

the costa a red-brown stripe to the centre of the cell, a reddish line from the centre of the hind-margin to the apex, at the distal margin expanded, a black transverse band to the tornus. Hindwing with a black distal-marginal band filled up with red-brown. All the veins black. Expanse of wings: 70 mm. Ecuador. (Was not at hand.)

lauronoides. **H. lauronoides** *sp. n.* (65 b). Body black, head and collar with white dots, patagia red-brown, end of thorax and abdomen above with two bluish-white subdorsal lines, beneath white. Forewing whitish hyaline, the margins and a broad transverse band to the tornus black, the veins in both wings broadly black. Costa of forewing with an orange-red stripe, somewhat interrupted before the transverse band, a similar stripe from the centre of the hind-margin to the centre of the distal margin bent at the tornus, extending to the hyaline subapical spot. Hindwing hyaline white, with a broad reddish-yellow distal-marginal band which is bordered with black on both sides. Costa black. From the similar species comprised under *Lauron* it is distinguished by the less convex distal margin of the forewing. ♂ type from Massauary in the Berlin Museum.

The following species with a relatively broader transverse band of the forewing were hitherto mostly designated as *Lauron* (*Laurona*) *Wkr.* They strikingly resemble certain Diopitids, and some of the species which I was unable to examine may prove to be Diopitids. The colours of the body are often difficult to recognise in specimens belonging to collections. The abdomen is above almost invariably blackish with greyish-blue subdorsal lines, beneath whitish, with a black median line. — They copy Erycinids and Danaidids (*Leucothyris* and others).

syma. **H. syma** *Wkr.* (65 e). Thorax black, patagia red-brown. Wings greyish hyaline, apical part of forewing black, with a white subapical band not reaching to the margins, its veins being white. Margins of hindwing and all the veins black. — Its extremest form is f. **flammicollis** *Dgn.* (= *albiplaga* *Schs.*) (65 e). Wings quite black, with a blue reflection, not hyaline, the white subapical band short and broad. It particularly occurs in the ♂ and is connected with the type by all kinds of transitions. Brazil.

leucophaea. **H. leucophaea** *Wkr.* (= *osiba* *Drc.*) (65 e). Thorax blackish-brown, patagia red-brown. Ground-colour of the wings in the ♂ hyaline white, in the ♀ quite dark greyish hyaline, veins black. Forewing with a black costal margin and hind-margin and apical half, the latter with a white subapical band in which the hindmost vein is dark at most. At the costal margin and hind-margin an orange longitudinal streak to the subapical band; the hind-marginal stripe is often shortened. Analis white. Hindwing with a black margin being at most partly filled up with reddish-yellow. Venezuela, Brazil, Peru.

partita. **H. partita** *Wkr.* (= *transita* *Mschlr.*) (65 d) is quite similar to *leucophaea*, in the forewing the analis is black, the subapical band is veined black, at least two veins black. Hindwing frequently with a reddish-brown filling of the marginal band, the hyaline areas of the ♀ are much more transparent, less greyish. Range like in *leucophaea*, perhaps only a form of it. It copies the Erycinid *Esthemopsis lithosina* *Bat.* (Vol. V, pl. 128 b).

peritta. **H. peritta** *sp. n.* is quite similar to *partita*, but the margin of the hindwing is here quite black, strongly expanded at the anal angle and continued to the base. Costa of forewing only before the transverse band with a yellow spot, costa basally to it whitish. Anal vein white. Venezuela, Brazil. ♂ type from Bahia in the Berlin Museum.

sora. **H. sora** *Bsd.* (= *panamensis* *Btlr.*, *domingonis* *Btlr.*) (65 d) is similar to the two preceding species, the subapical band of the forewing almost reaches the margins of the wings, without black veins, margin of hindwing much narrower, quite black, analis of forewing black, costal stripe and hind-marginal stripe red-brown, a similar stripe proximally to the subapical band in the ♂. Wings in the ♀ as greyish hyaline as in *partita*. Mexico to Panama.

leucophlebia. **H. leucophlebia** *sp. n.* (65 e) is separated from *sora* and *soroides* by the white analis and broader, quite black margins of the hindwing in the ♂; the ♀ has only a linear costal stripe, subapical band at least with one black vein, shorter; *partita* ♂♀ have a reddish-yellow filling of the band in the hindwing, which is absent here, *leucophaea* has in the ♀ darker hyaline wings. In the ♂ a red-brown postdiscal band and apical area which are absent in the ♀. Thorax black. Massauary, Itaituba. ♂♀ type from Massauary in the Berlin Museum, ♂♀ from Venezuela in the Tring Museum.

soroides. **H. soroides** *sp. n.* (65 e) is separated from *sora* by the following marks: in the ♂ the distal margin of the hindwing with reddish-yellow filling at the anal angle, the same being the case in the ♀ which also shows a reddish-yellow band before the white subapical band. Also at the apex of the forewing in the ♂ and ♀ mostly dusted with reddish-yellow. Mexico to Colombia. ♂♀ types from Chiriqui in the Berlin Museum.

halizoa. **H. halizoa** *Drc.* Forewing reddish-orange, near the base hyaline, veins black, a subapical band of fine spots white; hindwing hyaline brownish-black, both wings beneath brownish-black, costal margin of forewing reddish-orange. Jamaica.

vinosa. **H. vinosa** *Drury* (= *ergolis* *Wkr.*, *horologica* *Goeze*) (65 e) is similar to *soroides*, but the thorax is quite red-brown, the hyaline areas of the wings in both sexes darker. West Indies.

rica. **H. rica** *Hbn.* (65 f). Thorax quite reddish-yellow, wings still darker, scarcely hyaline. Forewing with reddish-yellow stripes only at the costal margin and hind-margin. Venezuela, West Indies.

H. chthonophyla Drc. (65 f as *chthonophila*). Wings blackish-brown, with a slight violet reflection, *chthonophyla* without hyaline areas, forewing with a white subapical band. Thorax red-brown. Mexico.

H. rufilinea Wkr. is unknown to me. ♀ black, forewing with an ochreous line at the costa and hind-margin, sometimes small ochreous spots at the distal margin, with a white subapical band. Expanse 55 to 60 mm. Ega.

H. diastilba sp. n. (65 f) is very small, length of forewing in the ♀ 16 mm. Thorax ochreous, wings *diastilba* black, at the bases more or less hyaline, on the hindwing more extensively so. Costa of forewing basally to $\frac{1}{3}$ ochreous, subapical band only 1 mm broad, otherwise similar to *chthonophyla*. Jamaica. ♀ type in the Tring Museum.

H. hoppi sp. n. (65 f) is one of the largest and most beautiful species, named after its discoverer WERNER *hoppi*. HOPP. Body black, head and thorax with greyish-blue spots, abdomen with greyish-blue subdorsal and lateral stripes, beneath greyish-blue. Wings bluish hyaline, costa, hind-margin, and apical third black, at the costa a red-brown basal streak, a similar one on the hind-margin where it is only absent in the basal quarter, but continued to the subapical band which is very broad, white. Hindwing with a black distal margin filled up with red-brown; all the veins black. Colombia. ♀ type from S. Francisco (Mocoa) in the Berlin Museum.

H. subafflicta Wkr. resembles *hoppi*, but lacks the reddish-yellow markings. Colombia, Bogota. (Per- *subafflicta*. haps only a race of *hoppi*.)

H. batesi Drc. (65 f). Forewing blackish-brown with a reddish-yellow costal streak from the base to *batesi*. $\frac{1}{2}$ of the wing, a similar bent subapical band extending to the tornus where it ends very narrow, whilst at the costa it is at least 5 mm broad. At the cell-end a whitish hyaline spot, another one behind it. Hindwing whitish hyaline with a broad black distal margin and costa, the former with a reddish-yellow submarginal band. Amazons, Peru. The species copies the Erycinid *Comptosia cascella* Hew. Vol. V, pl. 127 h) and the Danaidid *Pseudoscada aureola* Bat. (Vol. V, pl. 41 b).

H. padua Drc. is unknown to me. From *batesi* it differs in the posterior half of the cell of the forewing *padua*. and the area behind the cell as far as the axillaris being whitish hyaline. Ecuador.

H. scotina sp. n. (65 f) is distinguished from *batesi* in the hindwing by black veins and a broader black *scotina*. margin; in the forewing the cellular spot is reduced. Amazons. ♀ type from São Paulo in the Berlin Museum.

H. melania sp. n. (65 g). Hindwing reddish-yellow, with a very narrow (1 mm) black margin, a broad *melania*. black apex and a black clouded central spot above the posterior half of the cell. Forewing with a reddish-yellow costal streak as far as about $\frac{3}{4}$, hyaline spots as in *batesi*, hind-margin with a reddish-yellow stripe which is continued to the centre of the distal margin; it is then anteriorly prolonged by a hyaline white, not very much expanding, subapical stripe. Habitat illegible on label. ♀ type in the Berlin Museum.

H. putumayana sp. n. (65 g). Hindwing as in *batesi*, of the reddish-yellow submarginal band only traces *putumayana*. at the anal angle are noticeable. Forewing black, behind the cell on the 2nd cubitus with a large whitish-hyaline spot. Costa, hind-margin and apical third reddish-yellow, the borders finely black. Colombia. ♀ type from Sanbico, R. Putumayo (W. HOPP) in the Berlin Museum. The four forms mentioned last may be the races of one species.

H. chariata Drc. and the following are unknown to me. Thorax black, wings whitish hyaline, veins *chariata*. black, costal margin of forewing and distal margin broadly chrome-coloured, distal margin edged with black, hind-margin black. Hindwing with an ochreous, black-edged distal margin, and a black costa. Expanse 38 mm. Ecuador.

H. choma Drc. Thorax orange. Forewing black, hyaline to the centre, costal margin at the base *choma*. yellowish, hind-margin and two spots on the distal margin yellowish, a white subapical band. Hindwing hyaline, veins black, apex black, distal margin broadly orange. Fringes black. Expanse 35 mm. Ecuador.

23. Genus: **Scearctia** gen. nov.

The only species known recalls Diophtids. Hind tibiae with but 1 pair of spurs. In the forewing the 1st radial is separate, the 2nd to 5th forked, the 5th rising before the 2nd before the 3rd and 4th, the stalk of the 2nd to 5th rising at the anterior cell-angle, with the 1st median from the same place. In the hindwing the 2nd median branch is nearing the 3rd, the distance from the 3rd median to the 1st cubitus is at least twice as great as that from the 2nd to the 3rd medians. Type of the genus: (*Gangamela*) *figulina* Btlr.

Sc. figulina Btlr. (65 i). Body blackish-brown, abdomen above and beneath with whitish-grey, in- *figulina*. distinct lateral stripes. Forewing yellow, costa, hind-margin, and apical third blackish-brown, of the same colour a broad streak on the analis and some veins. Hindwing blackish-brown. Beneath in the forewing the streak on the analis is extended to the hind-margin, the veins being yellow. Brazil. It copies the Erycinid *Mesenopsis albivitta* Lathy (Vol. V, pl. 138 b) and the Diophtid *Myonia basivitta* Prout.

24. Genus: **Stenognatha** Fldr.

Near to *Hyalurga*. The footstalk of the radials 2 to 5 with the 1st median branch from the same place or forked, separated from *Scearctia* by the non-projecting posterior angle of the cell of the forewing, ♀ antennae with long combs.

gentilis. **S. gentilis** Fldr. (65 f, g). Body brownish-ochreous, abdomen with 2 rows of white dorsal spots, in the ♂ beneath dingy white. ♂ wings hyaline, apical half of forewing, costa and distal margin of hindwing dark brown. $\frac{3}{4}$ of the costa and hind-margin of forewing and anal angle of hindwing red-brown. ♀ dark brown, two thirds of costa of forewing and a spot between the cell and axillaris, as well as the base of the hindwing as far as the cell red-brown. Veins in the ♂ and ♀ blackish-brown. Brazil.

25. Genus: **Graphelysia** Hmps.

A genuine Pericopina, since the anterior edge of the cell and the subeostal in the hindwing at the base are distinctly separated. In the forewing the 1st radial is separate, the 2nd to 5th forked, the 5th rising before the 2nd before the 3rd and 4th. The 1st radial with the 2nd cubitus on the same height. In the hindwing the radial ramus and the 1st median, and the 3rd median and the 1st cubitus rise on a short footstalk. — The only species of the genus was described by its author as *Elysius* and was placed by HAMPSON who branched off the genus *Graphelysia*, to the group corresponding with our *Phegopterinae*. It has therefore already been dealt with on p. 399 and is figured there.

strigillata. **Gr. strigillata** Roths. (49 h) exhibits the habitus of a Phegopterina. Body blackish-brown, collar, terminal tufts on the thorax and abdomen varying from yellowish-brown to red-brown. Wings varying from a lustrous-brown to black, forewing finely transversely irrorated with yellowish. Brazil.

26. Genus: **Syntomidopsis** gen. nov.

variegata. **S. (Eudule) variegata** Wkr. (66 a). Black, costa of forewing as far as $\frac{3}{4}$, a broad transverse band, and some longitudinal stripes in and behind the cell red, the latter also in the hindwing. Apex with 3 or 4 white subapical spots, a similar one at the tornus, hindwing with white, small submarginal spots. Body black, abdomen with white rings, patagia, thoracal stripes, basal spots on the abdomen red, in the ♂ the hindwings are reduced, only blackish. Veins similar to *Hyalurga*, radials 2 to 5 far before the cell-angle, near to the 1st, in *Hyalurga* nearer to the 1st median. Jamaica. This species is also a genuine Pericopina; the generic name mentioned above is proposed for it.

(27). Genus: **Paratype** Fldr.

Perhaps a Geometrid genus.

lacticolor. **P. laeticolor** Fldr. (66 a). Black, forewing in the basal half yellow, except at the hind-margin, with 4 black longitudinal rays, a yellow postdiseal band to the tornus; hindwing yellow, costa and distal margin broadly black. Expanse 47 mm. Colombia.

The following genus remained unknown to me, probably no *Pericopinae*.

(28). Genus: **Didaphne** C. Berg (= *Daphne* Neumögen)

The hindwing is said to have „7 veins“, it may therefore be a Syntomid. The venation is not accurately mentioned; it also resembles certain *Lithosia*.

cyanomela. **D. cyanomela** Neumögen. Head, prothorax, and abdomen of a glaring orange colour. Thorax and wings abound in a metallic blue. Costa and a broad marginal band black, the latter extending to the centre of the hind-margin. Expanse 46 mm. Cuba.

I append here some more genera not belonging to the genuine Pericopinae, among which, however, they are mostly looked for.

(29). Genus: **Crocomela** Ky. (Darna Wkr.).

This genus does not belong to the *Pericopis*; the subeostal of the hindwing rises from the cell; a basal noose at the base is not present, at most developed as a fold. The ♂ shows scent-areas on the hindwing, which are absent in all the Pericopinae and by which the genus approximates the *Lithosia*. From the latter, however, it is separated by exhibiting accessory eyes. For practical reasons we deal with it here. In the forewing the 2nd to 5th radials are forked, the 5th rising before the 2nd; in the hindwing the radial ramus and the 1st median are forked, all the other veins being separate; the posterior cell-angle is strongly produced. All the species similar to *Crocomela*, not belonging hereto, exhibit a distinct basal noose at the rise of the subeosta of the hindwing.

1. Wings mostly with a more or less intense blue lustre, hindwing without yellow marking. In the ♀ the yellow marking is generally somewhat broader than in the ♂. Body black, often with a blue lustre, rarely with yellow colourings.

C. colorata Wkr. Wings black, at the bases with a blue lustre, the yellow spot in the ♂ almost oval, 5 to 6 mm broad at most, in the ♀ posteriorly expanded, 6 to 7 mm broad. Length of forewing 16 to 20 mm. Colombia.

C. abadesa Dgn. (65 h) is similar to *colorata*, but smaller, forewing 16 to 17 mm long, the yellow band in the ♂ 4, in the ♀ 5 mm broad at most, somewhat darker yellow. Colombia.

C. regia Warr. Forewing and hindwing more extensively blue than in the preceding, the black margin of the hindwing only about 2 mm broad, the blue colour of the forewing being paler, extending near to the band; otherwise like *C. colorata*. Ecuador.

C. imperialis Drc. resembles *abadesa* (65 h), but the yellow band is at the costa very narrow, 3 mm broad (♀), maximum 5 mm. The blue lustre strongly developed in a similar way as in *regia*. (Was not at hand.) Ecuador, Chiguinda.

C. unifasciata Drc. (♂ = *rubiplaga* Warr.). Forewing brownish-black, with an orange-red, large (maximum 6 to 8 mm) discal spot. The area from the base to the discal spot is pale grey. (Was not at hand.) Ecuador.

In the following species the yellow band is broadest at the costa, whence it narrows down.

C. inca Schs. (65 g). Base dark blue, band 7 to 8 mm broad (♀), length of forewing 18 mm. Hindwing in the ♀ almost black, only at the anal margin blue traces. Chanchamayo, Peru.

C. maxima Drc. (65 g, h). Forewing 19 (♂) to 26 (♀) mm long, the yellow band relatively narrower, at the costa 5 (♂) or 7 (♀) mm broad; base of wings not with an intense lustre, but dull greyish violet, Bolivia.

C. minima sp. n. (65 h) is similar to *maxima*, the yellow band here also extends almost to the margin, but it is smaller, length of forewing 16 (♂) to 19 (♀) mm, band 4 (♂) to 5 (♀) mm at the costa, bases of wings with a dark blue lustre. Bolivia. ♂♀ types in the Berlin Museum.

C. conscita Drc. (= *volitans* Warr.). Forewing black, scarcely lustrous blue, with a large yellow spot which at the costa is strongly extended towards the base; the costa itself remains finely black. The bordering of the yellow spot extends from $\frac{2}{3}$ of the costa hardly bent almost to the end of the 1st cubitus and bends round before the 2nd towards the base, from there it extends convex as far as shortly behind the rise of the axillaris, the foremost part of this convex bow being situated shortly behind the rise of the 2nd cubitus, not touching the cell and finally with the last part about on the axillaris to the base of the wing. Hindwing black, in the ♂ anteriorly lighter with a brown scent-spot surrounded by ochreous. Peru, Chanchamayo.

C. praelata Warr. is similar to *conscita*, the distal edge of the yellow spot arises nearer the apex, extending to the end of the 3rd median, where it bends in a right angle to the end of the 2nd cubitus. (The species was not at hand.) Peru, like the preceding.

C. flammifera Warr. (♀). Wings blackish-purple, with a reddish-orange spot of a similar shape as in the preceding, its distal edge arising from about $\frac{2}{3}$ of the costa and likewise running to the end of the 3rd median, whence it extends close at the margin to the 2nd cubitus. From there it likewise goes with a convexity to the base, which, however, touches the posterior margin of the cell. Expanse of wings: 50 mm. South-East Peru, Limbani, in November. (Was not at hand.)

C. orthocraspeda sp. n. (65 g) is quite similar to *flammifera*, the distal edge of the orange spot extends almost straight to shortly before the end of the 2nd cubitus, not being angularly bent at the 3rd median, extending about from the centre of the 1st cubitus along it and then along the posterior margin of the cell to the base. South East Peru, like the preceding, in March. ♂ type in the Tring Museum. It is not impossible that this species is the ♂ of the preceding or another generation of them. But as the species of *Crocomela* often fly together, this question cannot be decided yet.

C. trigonata Warr. (♀) is separated from *conscita* Drc. and *flammifera* Warr. by the much broader orange area of the forewing; its distal edge extends from $\frac{1}{2}$ of the costa to the distal margin, before which it bends round on the 1st cubitus and goes to the axillaris, from where it extends, roughly bordered and narrowing down, to the base of the wing. (Was not at hand.) Peru, Huanuco.

2. Also the hindwing with light markings.

C. intensa Wkr. (♀ = *marginata* Warr., *vitellina* H.-Schäff.) (65 i). Deep yellow wings, with broad, black distal margins, forewing from the base broadly black, this border being then narrowed; about from the centre of the costa the broad black margin begins, occupying the apical third and extending bent to about $\frac{4}{5}$ of the hind margin. Hindwings at the costa without a black border, in the ♂ the anterior half of the wing is pale, not scaled, with an oblong brown scent-spot. Venezuela.

- erectistria*. **C. erectistria** Warr. (= *elisa* Drc.). Wings black, forewing with a yellow longitudinal streak (about 2 mm broad) pointing towards the apex and being more (♂) or less (♀) narrowed, ending before the margin in the distance of its greatest width, the last end being very feebly bent upward like a hook, or in the ♂ even being deposited in a dot. Hindwing yellow with black margins, which are broadest at the posterior margin of the 3rd median branch. ♂ beneath with black scales on the anterior angle of the cell, ♀ beneath with a yellow stripe on the basal costa. Ecuador.
- fusifera*. **C. fusifera** Wkr. is not determinable from the author's short description; wings pale yellow, rather long, moderately broad, with black margins which are much broader on the forewing than on the hindwing. Length of wings about 32 mm. Colombia, Bogotá.
- luxuriosa*. **C. luxuriosa** sp. n. resembles *erectistria* Warr., the yellow colouring is more extensive, on both wings only ending 1 mm before the margin, so that the yellow colouring is at the 2nd median branch much farther extended towards the margin. In the ♀ the area between the subcostal and the cell of the hindwing is dusted with blackish. Colombia. ♀ type from the Rio Dagua in the Berlin Museum.
- tenuifascia*. **C. tenuifascia** sp. n. In the distal extent of the yellow colouring between *luxuriosa* and *erectistria*, the yellow areas narrower, that of the forewing in the maximum 1½ mm broad, paler yellow. Beneath the costa of the hindwing is brown at the base. Ecuador. ♀ type in the Berlin Museum.
- latimargo*. **C. latimargo** Dgn. (65 i). Wings black, forewing with a very broad yellow longitudinal spot from the base, anteriorly extending to the centre of the cell, posteriorly beyond the axillaris, cutting the latter about in the centre and being at the end (about in the area of the transverse vein) broadly truncate and somewhat emarginated. Hindwing similar to that of *erectistria*, but the black anal-marginal border is somewhat narrower. Colombia.
- acuminata*. **C. acuminata** sp. n. (65 h) is similar to *latimargo*, the yellow central spot of the forewing, however, almost extends to the centre of the 3rd median branch, it is pointed. Hindwing entirely as in *erectistria*. Colombia. ♂ type in the Berlin Museum. (This form is perhaps the ♂ of *fusifera* Wkr.).
- albolineata*. **C. albolineata** Drc. Described as *Josiomorpha*, unknown to me, but probably belonging hereto. In the scheme of markings similar to *erectistria* and its allies, but all the yellow markings are here white. Colombia.
- pluricineta*. **C. pluricineta** Dgn. is extremely similar to *Antiotricha integra* Wkr. (38 f), but on all the wings the costal margin is broader black, fully one millimeter broad on the forewing (in *integra* about half a mm). Wings otherwise orange, all being margined with black. Colombia. The species was not at hand.
- cecata*. **C. cecata** Dgn. (♀). Wings orange, margined with black (except the costa and anal margin of the hindwing), also similar to *integra*, but the forewing with a black transverse line in the centre. Ecuador. The species was not at hand, perhaps it does not belong hereto.
- furonia*. **C. furonia** Drc. (♂). In the size (expanse of wings 35 to 40 mm) corresponding with *cecata*, but it has 3 white dots on the collar, and the costal margin of the hindwing is said to be black; otherwise similar to *cecata*, perhaps the ♂ of it. It was not at hand. Ecuador.

NOTE: *Darna tripunctata* Dr. is a *Micrarctia*, allied to *Hetiactinidia*. *Darna formosa* Dogn. is a Geometrid; the same is probably the case with *Darna splendens* Drc. which is unknown to me (habitus of *Cr. Colorata*, hindwing at the costa near the apex with a yellow spot), and with *Darna grandis* Drc. (similar to *splendens*, hindwing with a yellow costal streak almost to the apex and a yellow streak from the base to the apex and a yellow streak from the base to the centre of the wing).

30. Gattung: **Episcea** Warr.

This genus also contains no genuine Pericopinae; but as it is frequently reckoned to it, it may be mentioned here. Separated from *Crocomela* by the absent sexual differences, otherwise rather similar to it in the veins, but in the examined specimen *Ep. sancta* the 2nd radial in the forewing arises from the same place with the 5th. Antennae in both sexes strongly pectinate. Accessory eyes present.

- sancta*. **E. sancta** Warr. (65 i) strikingly resembles the Dioptid *Scea auriflamma* Hbn., but in the forewing the proximal bordering of the apical black colouring runs straight, the latter being therefore more extensive. The anal margin is narrower black, so that there is yet some ground-colouring between it and the axillaris. The analis is broader black, particularly towards the base, than in *auriflamma*. The dark apical parts and the hindwing is chocolate brown, in the forewing the veins are lighter; beneath in the forewing a broad black stripe from the base along the proximal margin. Sa. Catharina.
- extravagans*. **E. extravagans** Warr. (65 i) resembles still more the said Dioptid, the markings as in *auriflamma* almost black. Otherwise separated from *Scea* by the straightly cut off apical part of the forewing; beneath the basal part of the hind-margin of the forewing is not black. Rio de Janeiro.

(31). Genus: **Gardinia** Ky.

No accessory eyes, consequently the genus belongs to the Lithosiinae. In the forewing the 1st radial is separate, anastomosing with the subeostal; the 2nd radial is separate (in a ♀ forked with the 3rd to 5th, so that the 2nd radial arose before the 5th before the 3rd to 4th). The 2nd and 3rd median branches are forked, the others separate. In the hindwing the cell in the ♂ is very short, changed by the scent-organ. The subeostal as far as the centre of the anterior margin of the cell fused with it, the radial ramus and the 1st median, as well as the 1st and 2nd cubitus forked. The species were hitherto all united under *magnifica*, they are only ascertainable by the ♂. All the species have a black body with a blue reflection, wings black, with a green or blue reflection, generally the forewing more golden green, hindwing varying from blue to violet.

G. magnifica Wkr. (65 i). ♂ at the antennal base without a place thickened by scales and covered with long hairs. Left valve of ♂ without a pointed terminal spine. Honduras, Nicaragua, Panama, Venezuela, Paraguay, Colombia. Length of forewing 27 to 32 mm. A more careful examination of the sexual armatures will necessitate a subdividing of this species.

G. amyntica sp. n. corresponds with the preceding in the size and exterior, antennae without a basal torus in the ♂, left valve at the end above extended into a spine, the curve of which is situate in the continuation of the valval convexity. Peru. ♂ type from Marepata in the Berlin Museum.

G. anopla sp. n. is a smaller species, forewing at most 25 mm long, ♂ antennae at the base with a black torus of scales, left valve of the ♂ without a terminal spine. In the ♀ there is before the much larger introitus vaginae a roundish protuberance which is indistinct in *magnifica*. Mexico. ♂♀ types in the Berlin Museum.

G. boliviensis sp. n. Size of *anopla*, ♂ antennae with an ochreous, black-haired torus of scales at the antennal base, which is just as thick as in *anopla*. Valves more unsymmetrical, left valve at the end twice as broad as the right valve. Bolivia. ♂ type from La Paz (Chaco) in the Berlin Museum.

G. paradoxa sp. n. Size of the preceding two species, the ♂ basal torus of scales likewise ochreous, black-haired, but much thicker. Left valve with a very long, entirely in-curved terminal spine, in the ♀ the vaginal area is very large, the introitus entirely removed to the left, the torus before it broad. Peru (Callanga, Chanehamayo). ♂♀ types from the Chanehamayo in the Berlin Museum.

Note:

Another imago may be mentioned yet, which had formerly been generally reckoned to the *Arctiidae* resp. *Hypsiidae* and has been figured by us on pl. 60 b:

Gypsius sumptuosus Wkr. According to recent statements by W. SCHAU, however, the species belongs to the group of the *Thyrididae* and will also be dealt with there. It originates from Mexico.

Additions to the Arctiidae.

Nolinae (p. 233).

P. 234, line 22, before *Nola niveibasis* insert:

habrophyes.

Nola habrophyes Dyar (66 b). Head and thorax of a pure white. Basal third of forewing white with a dark brown spot at the base of the costal margin; the distal two thirds of the forewing are blackish-brown, straightly cut off, scantily strewn with silvery blue scales; a faint, lighter postmedian line curved round the cell-end is noticeable, and before the apex some small light scales. Hindwing blackish-grey with a darker discal spot. Expanse of wings: 13 mm. Panama.

turbana.

N. turbana Schs. (66 b) is similar to the preceding, but it has brown shoulders; somewhat more than the basal third of the forewing is white, the distal half is lighter brown, only the straight nebulous stripe forming the border is dark; base of costal margin brown except a white basal spot; behind the centre there are at the costal margin fine white transverse lines, on the transverse vein a black spot round which a fine, black, dotted postmedian line makes a large curve. Hindwing whitish-grey, at the margin darkened. Expanse of wings: 12 mm. Guatemala.

Line 23 from below, before *N. pulverea* insert:

baracoa.

N. baracoa Schs. (66 b). Anterior body greyish-white, frons strewn with brown, abdomen light grey, at the base white. Forewing greyish-white, with a large, light brown spot at the base of the costal margin; from a smaller antemedian spot the fine black² anterior transverse line proceeds, behind which there is a brown spot in the cell; the similar black postmedian line arises from a spot in the centre of the costal margin, encircling the cell-end in a large curve, being strongly in-curved below the upper median branch, then again distally to the anal angle; a subterminal, light brown, spotted, irregular nebulous stripe. Hindwing white, at the margin light brown. Expanse of wings: 15 mm. Cuba.

folgona.

N. folgona Schs. (66 b). Head white, body grey like the forewing, the latter scantily strewn with brown, with a brown dot at the base of the costal margin; the punctiform transverse lines are composed of accumulations of brownish-grey scales, in the centre of the cell with small dark spots; subterminally are dark internerval streaks. Hindwing whitish, distally light brownish-grey. Expanse of wings: 13 mm. Cuba.

Line 16 from below, after *N. sabulosa* insert:

maria.

N. maria Schs. (66 b). Body and forewing light grey, towards the margin darkened, the transverse lines very indistinctly marked by darker scales, in the cell a black spot, at the cell-end accumulations of white scales, the punctiform postmedian line is proximally removed on the upper median branch; at the margin there are small dark spots. Hindwing white, fringes brown. Expanse of wings: 18 mm. Guatemala.

Line 12 from below, after *Nola mesographa* insert:

joanna.

N. joanna Schs. (66 b). Anterior body white, on the thorax mixed with brown. Forewing white, costal base striated blackish-brown; the fine antemedian line is almost removed into the centre, before it there is a black cellular dot, behind it blackish-brown shading, which is costally expanded into a large triangular spot; the posterior transverse line is very fine and feeble, brown, curved round the cell, from the lower median branch it extends vertically to the hind-margin with a short bent line before it; margin and fringes blackish-brown. Hindwing dark grey. Expanse of wings: 11 mm. French Guiana.

Line 9 from below, after *Nola triplaga* insert:

santamaria.

N. santamaria Schs. (66 b). Head white, collar blackish-brown, posteriorly bordered with white, thorax blackish-brown with white shoulder-covers. The white forewing is strewn with black, at the base of the costal margin a black spot with black dots before and behind it, before and in the centre there are some more black spots close together, from the former proceeds an undulate antemedian line, below the latter there are spots in the cell; the postmedian line being curved round the cell-end is blackish-brown, on the veins striped black, inwardly

downwards from the cell shaded with blackish-brown; marginal area broadly blackish-brown, in it a fine white undulate line interrupting the black veins of the marginal area. Hindwing whitish-grey, the postmedian line of the under surface showing through. Expanse of wings: 20 mm. Guatemala.

Line 3 from below, insert before *Nola perluta*:

N. limona Schs. (66 b). Anterior body and forewing white, the latter strewn with light brown, with a black, interrupted, anterior transverse line, with a round light brown cellular spot behind it; the fine black posterior transverse line is curved round the cell-end and extends from the lower median branch vertically to the hind-margin; the fine undulate line is proximally removed on the middle radial branch, forming small sagittae towards the hind-margin; in the dark grey marginal area there is a white marginal line with black vein-dots. Hindwing white, at the margin grey. Expanse of wings: 16 mm. Costa Rica; Guatemala.

N. yegua Schs. (66 b). Anterior body white like the forewing which is scantily strewn with a dark colour, at the costal margin spotted dark brown, in the centre a larger spot; the fine punctiform transverse lines extend as in *limona*; a subterminal irregular light brown shadow, the distal margin still lighter brown. The whitish hindwing is darkened brownish-grey towards the margin. Expanse of wings: 14 to 17 mm. Guatemala.

P. 235, line 3 from above, insert before *Nola biconica*:

N. elsa Schs. (67 b). Anterior body and forewing white, the latter scantily strewn with a darker colour, with traces of brownish transverse lines and accumulations of light brown scales in the cell; distally above them there is a triangular light brown costal spot; the feeble undulate line is followed by 2 rows of short marginal streaks. Hindwing whitish-grey. Expanse of wings: 12 mm. Guatemala.

N. cubensis Schs. (67 b) has an exterior very similar to *Roes. bifiliferata* (32 c). Anterior body and forewing white, the latter in the cell and above it red-brown, with double black transverse lines, the distal line below the lower median branch as far as the undulate black median line inwardly angular, from that place another line runs to the anal angle, shortly before it it incurves again; the undulate line is on the middle radial connected with the distal transverse line. Hindwing whitish, with grey veins. Expanse of wings: 18 mm. Cuba.

N. prothyma Dyar (66 c). Forewing whitish, at the margin grey with an irregular clouded submarginal line, a small dark spot at the base of the costal margin and with dusted, broken transverse lines, the anterior line being dentate, the posterior line forming two bows, the upper of which is larger; from a triangular brown median spot at the costal margin a straight line runs to the hind-margin. Hindwing brownish-grey, towards the margin darkened. Expanse of wings: 10 mm. Panama.

N. zeteci Dyar (66 c) has narrow forewings with almost parallel costal and hind margins. Forewing dark blackish-grey, with a dark costal-marginal spot at the base and a larger one near the centre, the latter being below indistinctly defined; the distal transverse line is oblique and dotted on the veins, like the undulate line. Hindwing lighter grey, at the margin darker. Expanse of wings: 14 mm. Panama.

N. rubescens Schs. (66 c). Forewing white, strewn with red-brown, with 4 large redbrown costal spots from which blackish transverse lines proceed, the distal line is proximally shaded with red-brown; marginal area red-brown with a fine white marginal line. Hindwing brownish-grey. Expanse of wings: 12 to 16 mm. Guatemala.

N. recedens Schs. (66 c). Forewing greyish-white, at the costal margin shaded with brownish with black transverse lines, the anterior line undulately dentate, with 4 black dots before it and a brownish-grey cellular spot behind it, the distal line punctiform, on one side shaded with brownish-grey; a dark subterminal shade is twice detached. Hindwing brownish-grey. Expanse of wings: 19 mm. Guatemala.

N. contorta Dyar (66 c) is on the forewing light grey, at the costal margin light brown, forming 2 spots situate close together, one between the accumulations of scales in the cell, the other close behind it; the feeble blackish transverse lines are broken, the proximal line undulate, doubled owing to spots accompanying it, the distal line curved round the cell is shaded with brown; the undulate line is also brownish. Hindwing brownish-grey with a darker median spot. Expanse of wings: 16 mm. Panama.

N. flavescens Dyar (66 c). Forewing light yellow, strewn with blackish, in the marginal area grey, distally and proximally darkened and here defined by the distinct black postmedian line against the yellow ground of the wing, in which there is a median shade; the indented dark undulate line is dentate. Hindwing brownish-grey, towards the base lighter. Expanse of wings: 16 mm. Panama.

Line 10 from above, insert after *Nola sperata*:

N. parana Schs. (66 c). Anterior body and forewing dull white, scantily strewn dark, particularly in and below the cell, at the costal margin towards the base brown; the anterior transverse line is very feeble, distally bent, the posterior line is proximally accompanied by a brownish-grey shade expanding towards the hind-margin; undulate line and marginal shadow dark greyish-brown. Hindwing brownish-grey, at the hind-margin whitish. Expanse of wings: 18 mm. Castro (Paraná).

nimbimargo. **N. nimbimargo** Dyar (66 c) is very similar to the following *chauma*, the marginal clouding is blacker, the undulate line obsolete, the distal transverse line dusted, dentate, the brown costal-marginal band in the basal two thirds distinct, at the end expanded into a small spot. Hindwing diaphanous brownish-grey. The species is also very similar to *artata* (32 k), but the distal transverse line does not form on the submedian such a distinct tooth. Expanse of wings: 12 mm. Panama.

chauma. **N. chauma** Dyar (66 c) is very similar to the following *artata*, but the costal spot is longer and extends more obliquely. Forewing whitish, at the margin grey, here crossed by the white undulate line; the blackish distal transverse line approaches the grey marginal area and forms 2 bows; costal margin shaded with brown, behind the centre forming a large spot. Hindwing brownish-grey, towards the margin darker. Expanse of wings: 9 mm. Panama.

Line 13 from above, insert after *Nola artata*:

aeschyntela. **N. aeschyntela** Dyar (37 c). Forewing light grey with accumulations of black scales, the anterior transverse line irregularly bent, the distal line punctiform, before it a black shade, at the costal and hind margins shaded with red-brown; undulate line blackish speckled. Hindwing brownish-grey, towards the base lighter. Expanse of wings: 14 mm. Panama.

brunneifera. **N. brunneifera** Dyar (67 a) is similar to the preceding, but the transverse lines have entirely disappeared in the black irroration which forms streaks on the veins; hind-margin and anal angle brown. Hindwing lighter. It may be the ♂ of the preceding species which was described from ♀♀. Expanse of wings: 12 mm. Panama.

rufizonalis. **N. rufizonalis** Hmps. Forewing silvery white with a red-brown spot at the base of the costal margin, a straight red-brown median band which narrows down below the cell, with a silvery white dot in it below the costal margin and at the cell-end; before the apex and at the margin large red-brown spots. Hindwing silvery white. Expanse of wings: 14 mm. Colombia.

Line 20 from above, insert before *apera*:

nephelepasa. **N. nephelepasa** Dyar (67 a) is light grey almost without any markings, only in the centre of the costal margin with an accumulation of darker scales as far as into the cell; the distal transverse line is marked by single dark scales, instead of the undulate line a shadow. The grey hindwing is basally lighter. Expanse of wings: 15 mm. Panama.

quintessa. **N. quintessa** Dyar (67 a). Forewing light grey, irrorated darker, particularly at the margins, with broad, almost straight, shaded, very oblique and parallel transverse lines; the dark subterminal shadow is far remote from the margin, distally undulately defined. Hindwing light grey. Expanse of wings: 13 mm. Panama. From *apera* (32 a) distinguished by the distal transverse line not forming any vein-dots.

P. 236, line 12 from below, insert after *Roeselia canescens*:

pecta. **Roeselia pecta** Dyar (67 a). Forewing whitish-grey, irrorated darker, with a rounded triangular, blackish-brown costal-marginal spot in the centre, and fine brown transverse lines, the posterior line undulate, before it in the lower half some small brown spots; the blackish subterminal line is irregular, behind it analwards brown shading at the margin. Hindwing brownish-grey, with a median spot. Expanse of wings: 15 mm. Panama.

hypopecta. **R. hypopecta** Dyar (67 a) is likewise whitish-grey, the costal-marginal spot in the centre almost quadrangular, black and extending down to the median; the anterior transverse line is removed into the centre near the posterior line which runs straight, before it the small brown spots are absent; the undulate blackish transverse line is distally followed by brown dusting leaving only the apex bare. Expanse of wings: 13 mm. Panama.

micropecta. **R. micropecta** Dyar (67 a). Forewing light grey, with a dark grey triangular spot in the centre of the costal margin; the transverse lines are fine, blackish, the distal line bending round the cell-end; in the grey-shaded marginal area is the still darker undulate line, the costal margin is finely speckled grey and white. Hindwing monotonously brownish-grey. Expanse of wings: 10 mm. Panama.

P. 236, line 1 from below, insert after *unilinea*:

castigata. **R. castigata** Dogn. Anterior body and forewing of a pure white, in the first third of the costal margin two black dots, and with a white median band edged with blackish-brown, the interior bordering begins at the costal margin with a brown triangular spot, the distal 2 mm distant from it, at the hind-margin only 1 mm, behind it with a blackish costal spot from which a brown faded line proceeds, vanishing again in the brown marginal shading and proximally accompanied by a similar line. Hindwing light grey. Expanse of wing: 16 mm. Amazons.

P. 237, line 4 from above, insert after *Roeselia trocha*:

inga. **R. inga** Schs. (66 d). Anterior body and forewing silvery white, basal fourth of costal margin black with a large dark brown costal-marginal spot in the centre, flowing together with a smaller cellular spot, both edged with blackish-brown; from the lower cell-end a vertical blackish-brown line extends to the hind-margin;

before the grey margin there is a brownish subterminal shadow, before and behind it at the costal margin one dark dot each. Hindwing whitish with a grey margin. Expanse of wings: 18 mm. Peru (Carabaya).

Line 24 from below, insert after *Roeselia effusa*:

R. trias Schs. (66 d). Anterior body and forewing white, on the wings tinted silky grey with a blackish-*trias*. brown anterior transverse line, a large V-shaped median spot at the costal margin, which is continued to the hind-margin as a line being angular at the lower cell-end; at the cross-vein a white line; the fine black distal transverse line at first runs almost parallel to the costal margin, becomes thicker after the bend and approaches very closely to the median line below the cell; the dark subterminal line is undulate, interrupted. Hindwing white with a fine brownish postmedian line. Expanse of wings: 23 mm. Peru.

P. 237, line 20 from below, insert after *R. hermana*:

R. pseudermana Dyar (66 d) resembles the preceding; forewing silvery grey with a long brown costal-*pseudermana*. marginal spot filling up the cell and ending sharply cut off at the distal edge of the reniform macula; both the similarly coloured maculae are marked by accumulations of scales; transverse lines single, the anterior line is a curved streak below the cell, the distal line is distally bordered with white, behind it the veins are finely striped black; the undulate line is only visible above and obliquely cuts off the apex. Hindwing greyish-white. Expanse of wings: 22 mm. Mexico (Chiapas).

Line 8 from below, insert after *Roeselia pedante*:

R. melletes Dyar (66 d). Forewing whitish, at the margin broadly irrorated with grey, with blackish-*melletes*. transverse lines, the proximal line broken, the distal line far curved round the cell-end below it double. The black undulate line is dentate and vanishes more or less in the grey marginal irroration; black marginal dots change off with black fringe-dots. Hindwing brownish-grey, towards the base lighter. Expanse of wings: 16 to 18 mm. Panama.

P. 238, line 4 from above, insert after *Roeselia dentata*:

R. varia B. & Linds. is similar to *dentata* Dyar (32 l) and *conspicua* Dyar (line 15 from below), the *varia*. latter of which is a distinct species and not a synonym to *fuscata* Grt. It differs from *dentata* in a more uniformly rounded and invariably double posterior transverse line, from *conspicua* in the much shorter palpi which in the latter species project by the length of the head. Ground-colour varying from dark grey to brownish-grey; the brownish grey median shadow begins with 2 costal-marginal dots and turns lighter towards the hind-margin; the light undulate line is irregular. From *minor* it is distinguished by a more sharply dentate postmedian line and a darker ground-colour. Expanse of wings: 26 to 32 mm. Arizona.

P. 238, line 20 from above, insert before *patina*:

R. caruscula Dyar (66 d) is allied to the following species, but smaller, the lines are lighter, the hind-*caruscula*. wing whitish without the grey shading. Expanse of wings: 12 mm. Mexico (Mirador).

Line 14 from below, insert after *Roeselia postalbida*:

f. **eucalyptula** Dyar (66 e) is larger and lighter than typical *minuscula* with entirely white hindwings *eucalyptula*. showing a faint median dot. Expanse of wings: 21 to 24 mm. Described from California.

After *Roeselia minuscula* we introduce as a distinct species, line 15 from below:

R. conspicua Dyar (66 e). Larger and darker than *minuscula* (32 f) with much longer palpi. From Colo-*conspicua*. rado and New Mexico, and in a somewhat lighter form from Winnipeg, Manitoba. The larva lives on oaks.

After it insert as non-synonymous with *minuscula*:

R. minor Dyar (66 e) is probably also a distinct species, still larger than *fuscata*, the forewing smoothly *minor*. scaled, grey, with finer markings, the distal transverse line is more distantly bent round the cell-end.

R. bicrenuscula Dyar (66 e). Forewing lustrous dark grey with 3 accumulations of raised brown scales *bicrenus-**cula*. in the cell; the two transverse lines are thin, black, both finely erenulate, the inner line regularly curved; behind the dark undulate subterminal shadow white irroration. Hindwing light brown, towards the base lighter. Expanse of wings: 28 mm. Arizona. Allied to *conspicua* from which it is distinguished by more distinct, finer markings.

R. extusata Dyar (66 e). Forewing dark grey, in the distal half of the cell with a quadrangular blackish *extusata*. shadow as far as the costal margin, with a white discal spot therein; transverse lines crenulate, the distal line far curved round the cell-end; the light, dentate undulate line is more or less broken up into spots, proximally bordered with a darker colour; fringes speckled. Hindwing dark brown. Expanse of wings: 25 mm. Arizona.

P. 239, line 24 from above, insert before *metaleuca*:

R. atypica Dyar (66 d) has whitish forewings scantily strewn with black, with a dark spot at the base of *atypica*. the costal margin, a curved anterior transverse line, the posterior line parallel to the margin bordering on an

oblique dark costal-marginal spot; the finely crenulate subterminal line is likewise parallel to the margin on which the grey irroration becomes denser. Hindwing light, on the veins and margin brownish-grey. Expanse of wings: 15 mm. Panama.

P. 239, line 14 from below, insert after *medioscripta*:

emissa. **R. emissa** Dyar (66 d). Forewing dark grey, the posterior transverse line single, distinctly black, with vein-streaks; in the centre of the costal margin a triangular spot extends along the upper median branch almost to the distal line; at the base a dark shadow, behind it the feeble, fine, anterior transverse line; the undulate line is only marked. Hindwing whitish with finely darker veins and margin. Expanse of wings: 23 mm. Mexico (Zacualpan?).

clarciana. **R. clarciana** Dyar (66 e). Forewing light grey, at the base and above the cell whitish, with a triangular black spot at the base of the costa and a black median shade covering the proximal half of the reniform macula, the distal half being white, without a border-line; the distal transverse line is double, curved round the cell-end; behind the dark, speckled undulate line brightened up by whitish, on the margin black dots. Hindwing light grey. Expanse of wings: 29 mm. Mexico (Hidalgo).

P. 240, line 19 from below, insert after *appelia*:

phacotermi-
na. **C. phaeotermi** Hmps. Anterior body and forewing white, the latter in some places dusted with red-brown and irrorated at the costal margin, with a dark brown marginal area, only towards the apex mixed with white; the accumulations of scales and a spot in the centre of the cell are red-brown; a faint red-brown, posterior transverse line is only visible in the upper third, behind it at the costal margin a small brown spot. Hindwing light brown. Expanse of wings: 14 mm. Peru.

sylpha. **C. sylpha** Dyar (66 d). Forewing whitish, with a light grey aspect owing to fine irroration, and a small brownish-grey costal-marginal spot near the base, a nebulous spot at the beginning of the proximal transverse line, and a larger oblique one behind the centre, from which the median line proceeds, all the three lines being brownish-grey; the clouded undulate line forms 3 bows. Hindwing light grey, at the margin darker. Expanse of wings: 11 to 13 mm. Panama.

Line 15 from above, insert before *semirufa*:

cogia. **C. cogia** Schs. (66 d). Anterior body and forewing of a pure white, the forewing at the costal margin as far as before the centre, at the hind-margin as far as behind the centre, behind it dark grey with feebly brownish postmedian, subterminal, and marginal lines with black vein-streaks therein; transverse vein marked brown and black. Hindwing whitish grey. Expanse of wings: 14 mm. French Guiana.

P. 241, line 7 from above, insert before *Celama albirufa*:

ralphia. **Celama ralphia** Schs. (66 e) has a white head; thorax and forewing are brownish-grey, forewing at the margin darker with a dark brown streak at the base of the costal margin and fine, punctiform transverse lines, behind the anterior line with a round black cellular spot; the distal line ends at the hind-margin with a faded brown spot; parallel to the margin a subterminal row of dots. Hindwing white, at the margin smoky. Expanse of wings: 13 mm. Guatemala.

euryppennis. **C. euryppennis** Dyar (66 e). Forewing white with blackish-brown markings: near the base a subcostal small heap of scales, behind it one at the costal margin which is finely spotted dark; the proximal transverse line consists of 3 dots, behind it a large cellular spot connected with the costal margin; the distal transverse line also consists of a row of dots; the brownish subterminal line is broad, undulate. Hindwing white, on the veins and margin somewhat brownish. Expanse of wings: 22 mm. From Utah, taken in July.

Line 10 from above:

obliquata. **C. obliquata** B. & McD. is synonymous with *lagunculariae* Dyar and must be placed to *Nola*. *lagunculariae* becomes a distinct species and is not synonymous with *apera*.

Lithosiinae (P. 241).

P. 242, line 9 from below, insert after *Boenasa nigrorosea*:

toryca. **Boenasa toryca** Schs. (66 e). Anterior body and forewing lustrous silky olive-brown, antennae, vertex and collar white. Marginal area of forewing suffused with white; below the cell a broad white area extending downward to the hind-margin, distally to behind the centre, the upper border-line being bent; on the transverse vein a white, distally black-edged streak, behind it a feeble bent postmedian line composed of dark irroration. Abdomen and hindwing conch-coloured pink. Expanse of wings: 17 mm. Cuba.

angelica. **B. angelica** Schs. (66 f) is very similar to the preceding, the pink colour is darker, also the vertex and collar are pink, the white hind-marginal area probably extends to the anal angle, it is strewn with olive-brown and in some places suffused with pink, upwards not extending to the cell and being above shaded darker. Expanse of wings: 18 mm. S. Domingo. Both species have accessory eyes and ought therefore to be placed to the Arctiinae.

2a. Genus: **Torycus** H.-Schäff.

Separated from *Boenasa* by the presence of all the veins in the hindwing which shows the normal shape and size. Only 1 species:

T. domingonis Schs. (66 f). Body and wings light drab, on the thorax and forewing tinted yellowish- *domingonis*. reddish, on the forewing densely strewn with blackish-brown except the marginal area, the irroration being subterminally intensified into a black line; on the transverse vein there are 2 black dots; from the base below the cell proceeds a white line bending downwards near the centre of the hind-margin. Expanse of wings: 13 mm. S. Domingo.

P. 245, line 10 from below, insert before *Clemensia*:

15a. Genus: **Anaene** Dyar.

Proboscis developed, palpi erect, the middle joint in front densely scaled, reaching the vertex with the short terminal joint. Hind tibiae with very long spurs. Forewing narrow, the costal margin bent down before the apex, the apex tapering off, almost falciform, only the uppermost subcostal branch being separate, in *Clemensia* the two uppermost; on the hindwing the upper median and the lowest radial branch are forked, the middle radial arises above the centre of the cross-vein.

A. spurca Dyar (66 f.) Forewing whitish with a dark brown costal margin, below it dusted with grey, *spurca*. crossed by 2 broad white lines, between both lines at the hind-margin a triangular brown spot; anal angle tinted yellowish, with a small dark spot in it, another one in the centre of the margin. Hindwing brownish-grey. Expanse of wings: 13 mm. Panama.

A. squalida Dyar (66 f) resembles the preceding, but the grey dusting is much more extensive and *squalida*. covers almost the whole wing; below a dark basal ray a whitish spot; the white transverse lines are narrower and do not reach to the costal margin; the dark spots are more olive and not so distinctly pronounced. Expanse of wings: 13 mm. Panama.

A. improspira Dyar (66 f). Forewing wood-coloured brown with numerous fine straight lines almost *improspira*. parallel to the distal margin with a large oblong discal spot. Costal margin copper-brown with fine white striae running towards the dark ones, and a small preapical spot; distal margin narrow dark brown. Hindwing greyish-brown. Expanse of wings: 10 mm. Panama.

A. diagramma Dyar (66 f), with longer palpi and the forewing below the apex somewhat fretted away, *diagramma*. is grey, the discal veins are lighter, dusted with yellowish, and very finely transversely striated alternately dark and light, with 2 blackish-brown transverse lines; at the costal margin, apex and distal margin there are small darker spots. Expanse of wings: 10 mm. Panama.

15b. Genus: **Dixanaene** Dyar.

Like *Anaene*, but on the forewing the upper median and the lowest radial branch are forked, the terminal joint of the palp is much longer, and the apex of the forewing is rounded. Only 1 species.

N. lepidocaena Dyar (66 f). Forewing lightgrey, very finely transversely striated whitish and dark *lepidocaena*. brown, with white spots at the base, in the basal third of the hind-margin and in a subterminal line, and with 2 copper-coloured transverse lines, the proximal one being shortened; between them with 3 spots of long, spatulate, black and white scales, a subbasal, median and subterminal one, all 3 not reaching the costal margin. Hindwing whitish, distally brownish. Expanse of wings: 11 mm. Panama.

P. 246, line 5 from below:

C. lactea Stretch is to be eliminated from the Lithosiinae; according to Mr. BENJAMIN it is an *Erastrina* *lactea*. and belongs to the genus *Grotellaforma* (= *colora* Barnes).

P. 246, line 8 from below, insert after *Clemensia urucata*:

Clemensia pontenova Dogn. Wings white, forewing behind and below the lower cell-angle tinted yellow- *pontenova*. ish, at the costal margin with 6 small brown strigiform spots: 3 before the centre, the third being the longest and extending obliquely to the cell-fold; behind the centre 2 close together, then enclosing a large black discal spot, the distal one extends as a light line not quite to the hind-margin; the sixth runs as a horizontal line below the apex; in the centre of the distal margin a brown shadow. Hindwing at the margin brownish. Expanse of wings: 13 mm. Amazons (Rio Xingu).

chala. **C. chala** Schs. (66 f) has greyish-white forewings with 4 small blackish-brown costal spots before the centre, below the most distal spot with a dark line, before which there is a large brownish-grey spot in the cell, followed by a smaller black spot; near the cell-end runs a second, irregular, interrupted transverse line, at the end itself a black discal spot; the postmedian line is fine, crenulate, in the lower half irregularly speckled; a subterminal brownish-grey shadow, behind it internerval spots; a submedian light brown shadow from the base to the distal transverse line is united here at the hind-margin with a large, greyish-brown, semicircular spot; the white fringes are spotted black at the apex and in the centre. Hindwing greyish-white with a central spot and small faint marginal spots. Expanse of wings: 18 mm. Guatemala.

Line 2 from below, insert before *brunneomedia*:

remida. **C. remida** Schs. (67 a). Allied to the following species. The white forewing is irrorated with light brown, the brown basal area is bordered by a dark brown line; the anterior transverse line is fine dark brown, before it a curved brown shadow, behind it a dark cellular dot; the postmedian line is a broad light brown shadow, partly finely bordered with dark, forming a brownish-grey spot below the cell-end; single brownish-grey, small subterminal clouds. Hindwing smoky grey. Expanse of wings: 20 mm. Guatemala.

P. 247, line 25 from above, insert after *Clemensia cernitis*:

holocerna. **C. holocerna** Dyar (66 g) is allied to *cernitis* (33 m), but it is browner, the costal margin before the apex more strongly bent down, forming an angular projection. Forewing brown with a dark brown costal-marginal spot before the apex, the transverse lines very feebly marked by darker irroration; the light undulate line is the most distinct, and forms a white border of the costal-marginal spot. Hindwing brownish-grey. Expanse of wings: 13 mm. Mexico (Tabasco).

P. 248, line 17 from above, insert after *Clemensia flava*:

plumbeifusca. **C. plumbeifusca** Hmps. The dark brown forewing is suffused with a silvery bluish grey; behind the centre an indistinct double row of white dots and a subterminal row of white dots. Hindwing coloured like the forewing. Expanse of wings: 18 mm. Peru.

Line 25 from above, insert after *Anaulosia*:

17a. Genus: **Geridixis** Dyar.

The generic marks correspond with *Chrysochlorosia* (p. 264), but on the forewing the uppermost subcostal branch arises separately from the cell; on the hindwing the cell is of normal size. Only 1 species:

minx. **G. minx** Dyar (66 g). Forewing white, somewhat irrorated with ochreous, the greatest part of the wing is occupied by an oval, large, black spot, so that only the costal-marginal third, a narrow distal-marginal area and the anal angle remain white. Hindwing brownish-grey with white fringes. Externally very similar to *Paratalara inversa* (pl. 34 m). Expanse of wings: 14 mm. Panama.

P. 249, line 6 from below, insert before *Talara barema*:

minynthadia. **Talara minynthadia** Dyar (66 g). Body brown, with a metallic black tint, neck and base of antenna yellow; abdomen above carmine, at the anus orange mixed with black. Forewing slate-coloured brown, at the costal margin and in the centre shaded with bluish-black. Hindwing carmine with a blackish-brown marginal band. The ♀ probably belonging to it lacks the dark shadow, the marginal band of the hindwing is much broader. Expanse of wings: 15 mm. Panama.

violescens. **T. violescens** Dyar (66 g). Forewing dark slate-coloured brown with a violet reflection. Hindwing black, in the basal third carmine. Abdomen carmine with a bluish-black anal tuft. Expanse of wings: 16 mm. Panama.

Line 1 from below, insert after *Talara leucocera*:

mesospila. **T. mesospila** Dyar (66 g). Head, thorax and forewing white, forewing with a brown spot in the basal third of the hind-margin and another oblique one at the anal angle. Hindwing and abdomen carmine. Expanse of wings: 11 mm. Panama.

P. 250, line 17 from above, insert after *Talara leucophaea*:

melanosticta. **T. melanosticta** Dyar (66 g) has slate-coloured forewings. Hindwing of a somewhat browner tinge with a large velvety black androconium in the disc. Expanse of wings: 15 to 16 mm. Panama.

Line 25 from above, insert after *Talara violaceogrisea*:

synnephela. **T. synnephela** Dyar (66 g). Forewing greyish-white with a black clouded spot above the anal angle and a subcostal lighter part. Hindwing and abdomen blackish. Expanse of wings: 14 mm. Mexico (Tabasco).

thea. **T. thea** Schs. (66 g). Anterior body drab, abdomen black. Forewing greyish-white, a stripe in the cell and a broad postmedian area from the upper radial branch to the hind-margin black, and the hind-margin is also broadly black and the distal margin inclusive of the fringes narrowly black. Hindwing black. Expanse of wings: 20 mm. Ecuador.

P. 251, line 18 from above, insert after *Talara diversa*.

T. mona Dyar (66 g). Forewing grey mixed with whitish, particularly towards the hind-margin; the *mona*. anterior transverse line is formed of 3 small light spots, the straight undulate line is dark, behind it a light spot at the anal angle and at the costal margin one dot each before and behind it. Hindwing and abdomen above earmine, hindwing with a dark grey apex narrowing down into a narrow margin at the anal angle. Expanse of wings: 11 mm. Panama.

Insert before *Barsinella*:

23a. Genus: **Abrochocis** Dyar.

This new genus was established for the structurally different *Talara esperanza* (p. 249, line 19 from below, pl. 32 n) as a typical species. On the forewing the two upper radial branches are on a long footstalk; on the hindwing the upper median branch anastomoses with the lower radial, the middle radial arising from the lower cell-angle. Separated from *Barsinella* by the bifurcation of the upper median and lowest radial branch and by the anastomosis of the uppermost radial and subcostal branches on the hindwing.

A. esperanza Schs. occurs also in Panama.

Line 13 from below, insert after *Barsinella mirabilis*:

Barsinella desetta Dyar (67 b). Forewing orange, dusted with red, with a earmine discal streak and *desetta*. margin; at the base there are 3 black dots followed by 4 finger-shaped streaks, then the trebly dentate anterior transverse line; the postmedian line has a long tooth, behind it are 8 black vein-streaks. Hindwing earmine with a black apical spot and orange fringes. Expanse of wings: 9 mm. Panama.

P. 253, line 19 from below, insert after *Lycomorphodes eptatra*:

Lycomorphodes genificans Dyar (66 h) is externally quite similar to *Talara rugipennis* (34 e), but has *genificans*. different veins. Forewing dark slate-coloured, hindwing of a purer black. Abdomen above earmine. Expanse of wings: 13 to 14 mm. Panama.

P. 254, line 17 from above, insert before *Ascaptesyle*:

30a. Genus: **Gaudeator** Dyar.

Proboscis developed; palpi short, erect as far as the centre of the frons. On the forewing the upper median branch arises before the lower cell-angle, the two lower radial branches are separated, the upper branch comes from below the upper cell-angle; the 3 lower subcostal branches are forked, the two upper ones arise separately from the cell, the uppermost is slightly bent. On the hindwing the upper median and the lower radial branch from the cell-angle, the middle radial from the centre of the cross-vein, the upper radial on a long footstalk with the lowest subcostal branch, the costal vein from the centre of the cell. Hind tibiae with two pairs of spurs.

G. paidicus Dyar (66 h). Body yellow, abdomen above tinted red. Forewing yellow with a purple black *paidicus*. basal streak; an oblique anterior transverse band is connected by a longitudinal streak with a curved posterior transverse band which is broken up into spots below the connection, its lower end terminating near the anal angle. Hindwing pink with yellow fringes. Expanse of wings: 13 mm. Panama.

Line 4 from below, insert after *Urozana cordatula*:

Urozana metaphaenica Dogn. Forewing and anterior body deep blackish-green, with a metallic red *metaphaenica*. iridescence. Hindwing black, in the abdominal half red. Abdomen black, posteriorly red, the hair-tuft ochreous brown, the anal tuft black. Expanse of wings: 16 mm. Brazil (São Paulo).

P. 255, line 11 from above, insert before *Nodozana*:

34a. Genus: **Serincia** Dyar.

Structured almost the same as *Cincia*, but on the forewing the second and third lowest subcostal branches anastomose. Only 1 species is described.

S. metallica Dyar (66 h). Head, thorax and forewing of a bright metallic green, hindwing and abdomen *metallica*. dull black. Expanse of wings: 16 mm. Panama.

Line 2 from below, insert after *Nodozana xanthomela*:

Nodozana albula Dyar (66 h). White, the forewing irrorated with yellowish, with a faded dark spot *albula*. behind the cell and a similar though black oblong submedian spot. Hindwing and abdomen light grey, abdomen with a white anal tuft. Expanse of wings: 11 mm. Panama. It looks externally like *Saozana leucota* Hmps. (*Odozana*, 341).

P. 256, line 24 from above, insert before *Metalobosia*:

35 a. Gattung: **Eugraphosia** *Hmps.*

Proboscis developed, palpi erect as far as the vertex. Forewing short and broad with a rounded apex, the upper median branch is forked with the two lower radials, the upper radial arises from the upper cell-angle; the middle subcostal branch is absent, the upper arises separately from the cell. On the hindwing the lowest radial branch is absent, the middle one comes above the centre from the cross-vein, the upper one is forked with the subcostal. The ♂ beneath shows a round, glandular swelling before the centre of the costal margin of the hindwing. Only 1 species:

rubrizonca.

E. rubrizonca *Hmps.* Anterior body and forewing white, in the basal half at the costal margin 2 brown dots, an oblique, brownish, faded transverse line is present only below the cell, a postmedian orange-brownish band is in the upper half oblique and narrower, in the lower broad and extending straight to the hind-margin; behind it a faded blackish line reaching neither the costal margin nor the hind-margin. Hindwing white, costal and hind-margins tinted brown. Expanse of wings: 16 mm. Peru (Rio Ucayali).

P. 257, line 16 from below, insert before *Illice*:

38 a. Gattung: **Jorgensenia** *Schs.*

Male antennae long-combed, female antennae serrate, palpi obliquely rising beyond the vertex. Hind tibiae with 2 pairs of short spurs. Forewing with a straight costal margin, the two lower radial branches on a short footstalk, the upper arises from the upper cell-angle; the three lower subcostal branches are forked, the 4th arises separately from the cell, and the uppermost anastomoses with the costal vein. On the hindwing the median branches arise forked from the cell-angle, the lowest radial is absent, the middle radial from above the lower cell-angle, the uppermost anastomoses with the subcostal vein. Only 1 species:

cunegunda.

J. cunegunda *Schs.* (66 h). Body and wings above black with a dull green reflection. Expanse of wings: 32 mm. Argentina.

Line 16 from below, add to *Illice*:

In this genus particularly North American authors have wrought assiduously, and many modifications have become necessary. For the species exhibiting the hindwing strongly lobate at the anal angle and with hairy clothing as well as a hair-lock at the anal angle of the forewing beneath the generic name: *Ozodania* Dyar has been established. Owing to the oldest determination of types by GROTE (1854), *Illice* would have to be substituted by the name *Cisthene* Wkr. with the typical species *subjecta*.

P. 258, line 21 from above, insert after *schwarziorum*:

subrufa.

Illice subrufa *B. & McD.* (66 h) (p. 259 line 22 from above) in correspondence with the structure described as *Ozodania*, is on the head and thorax light ochreous, on the abdomen pink. The forewing is greyish-brown, more or less dusted with ochreous, at the hind-margin near the base a light yellowish spot, not connected with a triangular one close before the anal angle, the latter, however, may be connected or not with a smaller costal-marginal spot by a fine yellowish line; at the edges of the light spots the brownish ground-colour is darkest. Hindwing deep pink with a smoky-grey apical spot. Expanse of wings: 13 to 16 mm. Texas. This may also be the Mexican form of *schwarziorum* with a pink under surface which in typical *schwarziorum* from Arizona is drab except the median band.

tenuifascia.

I. tenuifascia *Harv.* is to be eliminated from among the forms of *unifascia* (line 30 from above); the species has quite different genitals and, owing to a hair-tuft on the wing, it belongs to *Ozodania*. It is larger than *unifascia*, with a much narrower median band which is neither very broad at the costal and hind-margins. Texas, North Carolina.

Line 25 from above:

ruptifascia. **I. unifascia** probably only retains yet the forms: *kentuckiensis* Dyar with a very broad median band. — **ruptifascia** *B. & McD.*, which name would have to be substituted for f. *mexicana* Drt., is the form with a separated costal-marginal and hind-marginal spot; the yellow tints are in this form lighter and the pink colour of the hindwing is paler, more flesh-coloured. Described as a race from Texas.

perrosea.

I. perrosea Dyar (line 21 from below) is a distinct species with a different genital organ; a race of it is probably *angelus* Dyar (line 15 from below), since it exhibits the same type of the valval structure.

barnesi.

I. barnesi Dyar (66 h) (line 24 from below) is likewise a distinct species and not a form of *unifascia*; by the genital organ it is allied to *perrosea*, but it differs also from this species. *barnesi* occurs in 2 different colourings: the type with pink hindwings, and more rarely with yellow hindwings: = f. **flavula** *B. & McD.* (= *flava* Drt., ab. 6. *Hmps.*).

I. picta B. & McD. (66 h) is another species approximating *barnesi* by same structure of the genital *picta*. organ and being very much like *angelus* (33 a) in the exterior. Thorax quite yellow, the forewing with a broad yellow band along the hind-margin, connected with a yellow postmedian transverse band which is centrally very narrow. Hindwing pink with a smoke-grey apical spot extending narrowedly to the centre of the distal margin. By traces of hairs at the anal angle it approximates *Ozodania*. The species is much larger than *unifascia* (33 a) with which it is probably often confounded. Texas.

Line 7 from below, after *Illice abala* insert:

I. albizona Hmps. Head and thorax light greyish-brown, collar ochreous, abdomen crimson-hued *albizona*. pink, under surface of a yellowish white. Forewing light greyish-brown, with a straight yellowish-white median band bordered by slightly undulate lines. Hindwing crimson with a blackish-brown marginal band narrowing down analwards. Expanse of wings: 18 mm. Peru (Rio Ucayali).

P. 259, line 11 from above, after *Illice subrubra* insert:

I. bonitensis Schs. (66 i). Anterior body and forewing sand-coloured grey, neck and base of collar *bonitensis*. flesh-coloured like the abdomen and the hindwing, the latter with a broad grey margin narrowing down analwards. Expanse of wings: 13 mm. Brazil (Province of Pernambuco).

Line 19 from below:

I. packardii Grt. is presumably not a form of *subjecta*, but a distinct species which may approximate the following *conjuncta*, though at present nothing positive is known.

I. conjuncta B. & McD. (66 i) is allied to *subjecta* (33 b), but the spots are lighter and the whole *conjuncta*. area between the submedian fold and hind-margin is filled up by the white band. Head and thorax whitish, base of collar pink like the abdomen. Forewing dark smoke-grey with a white costal-marginal spot behind the centre and a broad white hind-marginal band expanding analwards into a large spot. Expanse of wings: 15 mm. Texas.

I. bellicula Dyar (66 i) is likewise allied to *subjecta* (33 b), the wings are narrower, the markings narrower *bellicula*. and softer, the pink colour much redder. Forewing grey with a pink spot in the distal third of the costal margin and one at the anal angle, the latter connected with the base along the hind-margin by a yellowish-white stripe. Hindwing pink with a large grey apical spot. Expanse of wings: 14 mm. Described from Florida.

P. 260, line 11 from below, after *Illice lycomorphodes* insert:

I. lincea Schs. (66 i) is a larger species with an orange head and thorax, and a reddish abdomen. *lincea*. Forewing orange, the basal third of the costal margin black with a black basal spot and one antemedian and postmedian costal-marginal spot each, behind the latter the black colour is continued round the apex on to the distal margin along the fringes which are distally white; in front of this a white area not reaching to the anal angle; another black spot is in the centre of the hind-margin and a shortened subterminal line before the apex. Hindwing orange-pink with a black apical spot. Expanse of wings: 18 mm. Guatemala.

Line 1 from below, after *triplagiata* insert:

I. leuconotum Dyar (66 i). Head and thorax white, abdomen above crimson. Forewing grey, irrorated *leuconotum*. with white so that the grey ground-colour merely borders on the spots: 2 oblong ones at the hind-margin, which are almost united and together extend almost from the base to the anal angle, and a semi-circular one at the distal third of the costal margin. Hindwing crimson with a minute grey apical spot. Expanse of wings: 10 mm. Panama.

I. flavizonata Dogn. Head and thorax black, collar and prothorax yellow like the base of the palpi, *flavizonata*. abdomen above red, beneath yellowish. Forewing black, traversed by 2 straight, obliquely extending, light yellow bands, the subbasal one of which does not reach to the costal margin, whilst the other one runs from the centre of the costal margin almost to the proximal angle. Hindwing red with a black marginal band which narrows down analwards. Expanse of wings: 14 mm. Colombia (Pacho).

P. 261, line 15 from above, to *liberomacula* add:

A form occurring more frequently than the type and deviating by a white stripe from the base along the hind-margin to the white postmedian spot has been called: **basijuncta** B. & McD.; it flies with the type *basijuncta*. in California.

P. 261, line 6 from below:

For *I. ruficollis* Schs. DYAR established the genus: **Paraprepia**, because the hindwing lacks the middle radial branch. HAMPSON placed *deceptans* Dyar as a synonym to it, for which, however, DYAR established the genus *Parillicz*, because the palpi are not erect, but only rise obliquely; *deceptans* is reported to differ besides from *ruficollis* in the orange posterior vertical part and collar. From Brazil.

To *Paraprepia* add yet:

fuscilingua.

Par. fuscilingua Dyar (66 i). Head and palpi bluish-grey like the thorax and abdomen, collar crimson. Proboscis dark brown. Forewing slate-coloured greyish-blue, in the proximal third darkened. Hindwing slate-coloured black. Expanse of wings: 15 mm. Panama.

P. 264, line 10 from below, before *Odozana* insert:

45a. Genus: **Palaeozana** Dyar.

Very closely allied to the Indian genus *Pachycerosia* (Vol. X, p. 188) from which it only differs in the costal margin not being convex. Proboscis well developed, palpi slender, erect; on the forewing the two lower radial branches rise from the same place, the uppermost from the upper cell-angle; the two upper subcostal branches rise separately from the cell; on the hindwing the two lower radial branches anastomose and are forked with the upper median branch, and the uppermost radial is also forked with the subcostal.

mida.

P. mida Dyar (66 i). Dark slate-coloured grey, the collar crimson. Forewing slate-coloured black, hindwing crimson with a uniformly broad black margin which is beneath set with rough orange scales. Abdomen crimson, the very large anal tuft in the centre orange. Expanse of wings: 15 mm. Panama.

P. 265, line 12 from below:

For *Odozana leucota* Hmps. a separate genus was established:

46a. Genus: **Saozana** Dyar.

Distinguished from *Odozana* by the separate uppermost subcostal branch of the forewing not anastomosing with the costal, and by the uppermost radial branch of the hindwing anastomosing with the subcostal vein; ♂ hindwing anally very much widened with a glandular knot above the lower median branch. Type: *S. leucota* Hmps. (341).

P. 267, line 13 from above, after *Th. dremma* insert:

theodula.

Thyone theodula Schs. (66 i). Anterior body orange, abdomen pink. Forewing orange with a black, metallic blue-scaled subbasal spot on the median and 3 (subcostal, median and submedian) black, blue-scaled longitudinal lines from before the centre to the distal margin, the uppermost and the median ones expanding distally, the submedian line thickened at both its ends. Hindwing grey. Expanse of wings: 18 mm. Guatemala.

P. 268, line 20 from above, after *Afrida flavifera* insert:

purulha.

Afrida purulha Schs. (66 i). Forewing white, in the basal third scantily covered with black scales, the central area thickly strewn with brown, edged by vertical black lines; the marginal third scantily strewn except an area between a fine black postmedian line and the vertical line which are united on the lower median branch. Hindwing greyish-white with a less distinct light brown median line. Expanse of wings: 16 mm. Guatemala.

P. 269, line 4 from above: to *Afrida ydatodes* add as synonym: *parva* B. & McD.

exegens.

A. exegens Dyar (66 k). Forewing grey with a broad white band behind the base with an irregular margin; a distal, very irregular band is composed of a long costal-marginal spot which is united with a round spot, then it filiformly extends to an anal spot, the white areas on both sides being bordered by black spots. Hindwing white with 2 grey undulate lines. Expanse of wings: 20 mm. Mexico.

Line 17 from above, after *A. coagulata* insert:

hemicycla.

Afrida hemicycla Hmps. has silvery white forewings with a black antemedian spot below the cell from which 2 fine lines extend towards the hind-margin, a black median streak and behind it 2 costal-marginal spots; behind the upper cell-angle with a black semi-circle the concavity of which shows towards the hind-margin; marginal area broadly red-brown, proximally defined by blackish. Hindwing white, towards the margin brownish-red. Expanse of wings. 14 mm. Colombia.

P. 271, line 9 from below, after *Josiodes celena* insert:

angustilinea.

Josiodes angustilinea Dogn. The black abdomen is in the ♂ only in the first half sublaterally striped ochreous. All the 4 wings are purple black, the forewing traversed by a rectilinear ochreous band of 1 mm width, which crosses the cell-end and taperingly ends at the anal angle. Expanse of wings: 29 mm. Amazons (Tapajoz).

P. 273, line 15 from above, after *Cisthene lunaris* insert:

monon.

Cisthene monon Dyar (66 k) differs from *lunaris* in the absence of the yellow subcostal patch. Body above yellow, beneath grey. Forewing slate-coloured grey with a narrow yellow median band and a uniformly

bent subterminal band which in the centre runs close at the margin, and recedes farther at the apex. Hindwing in the disc broadly yellow, with a small grey basal spot and dark grey marginal half. Expanse of wings: 27 mm. Venezuela (Merida).

Line 18 from above, to *Cisthene menea*:

C. arida *Skinn.* is to be cancelled from the synonyms and becomes a distinct species. The abdomen *arida*. is quite yellow, the hindwing in the basal half. The median band of the forewing is narrow, the subterminal band before the anal angle rounded, terminating as a spot. From Arizona.

After it insert:

C. chorion *Dyar* (66 k) is at once discernible from *arida* by the abdomen beneath being grey. *chorion*. Forewing slate-coloured black with a moderately broad orange-yellow median band and a rather broad subterminal band which is shortened at the anal angle. Expanse of wings: 33 mm. Mexico (Guadalajara). It may be a form of *arida*.

C. loccea *Schs.* (66 k) is closely allied to *menea* (35 i). Body of a deep yellow with black legs. Forewing *loccea*. brownish-black, median band and subterminal band narrow, the median one almost vertical, scarcely widened at the costal and hind margins, the subterminal one the broadest at the costal margin, very much nearing each other below the distal margin. Hindwing of a deep yellow, with a black marginal band of about $2\frac{1}{2}$ mm width. Expanse of wings: 27 mm. Guatemala.

Line 21 from below, after *Cisthene praxis* insert:

C. tehuacana *Dyar* (66 k) differs from the following *cypris* (35 i) in the almost quite black hindwing *tehuacana*. with but a small yellow costal spot. Forewing slate-coloured greyish-black, with a narrow yellow median band and a short crescentiform subterminal band. Head and thorax yellow, abdomen black except the base and the apex of anus. Expanse of wings: 24 mm. Mexico, Tehuacan (Puebla).

Line 17 from below, after *Cisthene uncinata* insert:

C. ducei *Schs.* (66 k) is bluish-black on the body and wings, whilst the vertex, collar and some hairs *ducei*. on the metathorax as well as the segmental indentations on the abdomen are orange; the median line on the forewing is 2 mm broad, straightly extending from the costal margin to the hind-margin; the subterminal band is still narrower and ends pointedly at the anal angle. Hindwing with a broad orange transverse band in the basal half from the costal margin to the hind-margin. Expanse of wings: 35 mm. Colombia.

Line 1 from below, after *Cisthene triplaga* insert:

C. abdulla *Dyar* (39 l) is monotonously black, on the wings a slight slate-coloured reflection, with a *abdulla*. yellow basal spot from the subcosta to the median, the hindwing with a small yellow costal stripe in the basal half. Expanse of wings: 26 mm. Mexico (Cuernavaca). Probably this insect coincides with *Cyanarctia basiplaga* = *Hypomolis lithosiaphila*.

P. 274, line 12 from above, after *Gnamptonychia orsola* insert:

Gnamptonychia ventralis *B. & Linds.* Forewing greenish black, in the ♀ greyer, hindwing dull brownish- *ventralis*. black. Anterior body likewise greenish black, the head, antennal base, palpi, collar, hips, femora, hind tibiae, and the underside of the thorax and ventrum of a bright orange. Expanse of wings: 38 to 45 mm. Arizona. This species is certainly very closely allied to *G. orsola* (32 i).

After this add:

62 a. Genus: **Grucia** *Dyar*.

Allied to *Gnamptonychia*, but without an accessory cell on the forewing which shows the two lower radial branches forked; the uppermost subcostal branch unites at the end with the costal vein. But one species:

G. monacheicauda *Dyar* (66 k) is unicoloured dark slaty-grey on the body and wings, the anal tuft *monachei-* *cauda*. is ochreous. Expanse of wings: 37 mm. Mexico (State of Hidalgo).

P. 275, line 25 from above, before *Pronola* insert:

66 a. Genus: **Vulmara** *Schs.*

To be compared with the Indian genus *Halone* (Vol. X, p. 186). Proboscis developed; the slender palpi erect, not reaching to the vertex. Forewing narrow with a straight costal margin, the upper median branch rises from before the lower cell-angle which sends forth the two lower radial branches, the uppermost rising from the upper cell-angle; the 3 lowest subcostal branches are forked, the two upper ones separate. Hindwing similar as in *Pronola*, but the middle radial rises directly from the lower cell-angle, the upper one is forked with the subcostal.

V. drostana *Schs.* (66 k) is quite monotonously blackish-brown, only on the forewing with a slight *drostana*. purple tinge. Expanse of wings: 18 mm. Guatemala.

66b. Genus: **Pachasura** Dogn.

Allied to the preceding genus. ♂ antennae shortly serrate with ciliary tufts. The forewing lacks the accessory cell. Veins as in *Vulmara*, but on the forewing the uppermost radial branch rises somewhat below the upper cell-angle. Hindwing also as in *Vulmara*, but the stalks of the forked veins are much longer, in the upper median and lower radial branch almost to the distal margin. But one species.

stellata. * **P. stellata** Dogn. Body above orange, with some bluish-black spots, ventrum bluish-black, anal tuft white, legs spotted black and white. Wings orange, forewing apically lighter yellowish, with 5 large bluish-black spots, a smaller subbasal one below the cell, 2 antemedian spots and 2 on the cross-vein and below it, and apically with 3 more minute strigiform spots. Hindwing with a large discal spot and a submedian stripe. Expanse of wings: 24 mm. Colombia (Pacho).

Line 9 from below, before *Eugonosia* insert:

67a. Genus: **Nudur** Dyar.

Veins as in *Pronola*, but the uppermost radial branch of the forewing rises from the upper cell-angle; on the hindwing the middle radial rises from the centre of the cross-vein. Palpi porrect. But one species:

fractivittarum. **N. fractivittarum** Dyar (66 k). Forewing ochreous, from the costal base a straight dark slate-coloured grey longitudinal band rises, extending to the centre of the distal margin; a short band is at the base of the hind-margin, another band at the anal angle, two similar ones are obliquely at the costal margin at the proximal and distal thirds, all these markings are bordered with red. Hindwing pink with a small dark apical spot. Expanse of wings: 18 mm. Mexico (Misantla).

P. 278, line 17 from below, after *Eudoliche major* insert:

osvalda. **Eudoliche osvalda** Schs. (66 k). Palpi and head white, body and forewing sand-coloured grey, the costal-marginal area white, not distinctly defined. Hindwing white. The wings are longer and narrower than in typical *Eudoliche*, and on the forewing the uppermost subcostal branch anastomoses with the costal. Expanse of wings: 24 mm. Cuba.

P. 279, line 28 from above, after *Macroptila laniata* insert:

rotundata. **Macroptila rotundata** Dogn. has lustrous white wings, the hindwing with a slight iridescence, the head and thorax slightly tinted grey, the scent-scales light ochreous. Forewing beneath in the lower half of the cell clad with long hair, towards the anal angle with shorter hair turned towards the apex, the costa roughly sealed, the costal margin of the hindwing likewise set with rough ochreous scent-scales. Expanse of wings: 25 mm. Panama, Colombia.

androconiata. **M. androconiata** Dogn. is the most closely allied to *crinada* (36 i) and differs from it in the smaller size with shorter and squatter forewings. The colour is a somewhat purer white; forewing beneath beside the long cellular hairs with an oval androconium from the centre of the lower median branch to the centre of the uppermost radial branch. Colombia (Quindiu Pass, Cauca Valley).

P. 281, line 7 from below, after *Agylla nivea* insert:

niphostibes. **Agylla niphostibes** Dyar (66 l) is very closely allied to *nivea* (37 c) and may be only a form of it, distinguished by the head being in front dark grey with a white vertex, and ochreous palps with black ends. Expanse of wings: 40 to 46 mm. Panama, Guiana.

arthona. **A. arthona** Schs. (66 l) is likewise very closely allied to *nivea* (37 c). Antennae brown, frons black, vertex white, between the antennae orange like the palps, neck and legs, only the middle tarsi are in front black. Thorax white, collar grey, abdomen ochreous-grey, at the end and below yellow. Wings silvery white, the costal margin orange. Hindwing thinly scaled, whitish grey. Expanse of wings: 35 mm. Guatemala.

P. 283, line 8 from above, after *Agylla barbula* insert:

cryptosema. **A. cryptosema** Hmps. Head and thorax grey, tinted red-brown, abdomen greyish-white, beneath tinted yellow, the anal tuft beneath red-brown. Forewing silvery white, below the hind-marginal vein red-brown, the costal margin towards the base set with short brown hair. Beneath tinted red-brown, hindwing with yellow hair-locks along the cellular fold, and with dark brown androconia. Expanse of wings: 36 mm. Colombia.

Line 11 from above, after *Agylla trichosema* insert:

bioptera. **A. bioptera** Dyar (66 l). Body grey with a black anal tuft, white frons and yellow palps with a black terminal joint. Forewing silvery white, along the hind-margin dark grey. Beneath the forewing is grey, at the hind-margin darker, in the cell and behind it with a broad ochreous area. The ♀ is beneath white, only at the anal angle somewhat grey. Expanse of wings: 20 to 22 mm. Panama.

Line 26 from above, after *meteura* insert:

A. tygriusa Schs. (66 l). Anterior body mouse-coloured grey, a dot on the frons and the edges of the collar except behind are white like the abdomen which exhibits a reddish-yellow anal tuft. Forewing broad with a pointed apex and a slightly roundish hind-margin. Costal-marginal half yellowish-white, hind-marginal half sand-coloured grey. Hindwing longer than forewing, white. Forewing beneath light yellow, the distal margin obliquely from the apex to the centre of the hind-margin set with brownish-black scent-scales. Expanse of wings: 32 mm. Ecuador.

P. 287, line 3 from below, after *Metareva endoscota* insert:

Metareva paulina Dogn. Wings of a brilliant white lustre. Forewing beneath below the cell with long fine hair. Expanse of wings: 28 mm. Amazons (Olivença).

M. susumuca Dogn. Anterior body grey, abdomen more whitish, beneath light yellow. Forewing glaringly white, at the hind-margin below the submedian fold tinted grey with a slight grey nebulous stripe along the median in the distal half of the cell. Beneath the forewing is brownish-grey with a yellowish tint. Hindwing white, at the costal margin and apex tinted grey. Expanse of wings: 38 mm. Colombia.

P. 290, line 24 from below, after *Progona xanthura* insert:

Progona ignata Schs. (66 l). Body brown, collar reddish-yellow like the anal end. Forewing light sand-coloured grey, along the costal margin with a white line. Expanse of wings: 13 mm. Brazil (Sao Paulo).

P. rioma Schs. (66 l). Body and forewing deep greyish-brown, hindwing more blackish. Expanse of wings: 20 mm. Mexico (Vera Cruz).

P. madeira Dogn. Body and wings dull blackish-grey, at the costal margin in the centre yellow; legs above black, beneath and at the tarsi yellowish. Expanse of wings: 20 mm. Amazons (Rio Madeira).

P. venata Schs. (66 l). Anterior body dark grey, palpi, vertex, and collar dark yellow, abdomen above blackish-brown, beneath yellow. Forewing brown, costal margin orange, the veins finely yellowish. Hindwing black with grey fringes. Expanse of wings: 25 mm. Paraguay.

Line 2 from below: the author of *casta* is SANBORN, not PACKARD.

P. 291, line 1 above:

Crambidia cephalica G. & R. is a distinct species.

After this insert:

Crambidia myrlosea Dyar (66 l). Head white, thorax grey; forewing dark grey with a broad white costal-marginal area, somewhat lighter veins, especially towards the costal margin. Hindwing dark grey. Expanse of wings: 22 mm. From Texas, taken in June and October.

C. cinnica Schs. (66 l). Body and forewing of the colour of raw silk, anal hairing lighter reddish-yellow. On the forewing the veins are lighter reddish-yellow. Hindwing darker smoke-coloured grey with whitish ends of the fringes. Expanse of wings: 23 mm. Mexico (Tampico).

P. 292, line 11 from above, after *Disoidemata quadriplaga* insert:

Disoidemata nicephora Schs. (67 a). Body reddish-yellow, collar and wings white, the forewing at the costal margin, in the distal-marginal interspaces, at the base of the hind-margin, and below the cell-end dusted with reddish-yellow, with 2 faded transverse lines and a small dark median spot. Expanse of wings: 15 mm. Guatemala.

D. conspersata Dogn. is white on its body and wings, but the palpi are ochreous; base of costal margin blackened, with 2 faded, oblique costal-marginal patches composed of red-brown atoms before and in the centre, and with one subterminal and small distal-marginal blackish-brown spots. Expanse of wings: 14 mm. Amazons (Rio Xingu).

Micrarctiinae.

P. 295, line 9 from above. *Eubaphe fragilis* Streck. (38 c), the type of which was examined, belongs to *immaculata* Reak. (38 a) (as forms of one species). What is usually presumed to be *fragilis*, however, is an insect with much shorter palpi and a Colorado-form of *costata* Stretch which, owing to the lighter colour of the wings, has been denominated **pallipennis** B. & McD. pallipennis.

Line 14 from above: *Eubaphe laeta* Guér., according to BARNES and McDUNNOUGH, has a northern and a southern race; the typical form described from the south must remain called *laeta*, whereas **treatii** Grt. *treatii*. (= *rubropicta* Pack.) is the name of the northern form (described from Massachusetts).

P. 295, line 8 from below insert:

cyana. **Eubaphe cyana** Dgn. has brown forewings and in the hindwing no yellow, but the whole basal half dark blue. Thus it resembles the exterior of *Stenucha dolens* (43 a), an Arctiid that has been described by the most various names. *E. cyana*, however, is easily discernible from it by the ♂ (the ♀ is unknown) exhibiting a white stripe through the cell on the hindwing. Colombia.

P. 296, line 10 from above, after *Virbia sanguicollis* insert:

orola. **Virbia orola** Dyar is likewise black on the head and body, with a red collar; forewing brown; on the hindwing the yellow spot reaches to the costa; somewhat smaller, otherwise like *sanguicollis* (38 d). Panama.

fluminea. **Virbia fluminea** Schs. from Costa Rica. Like *orola*, but the spot on the hindwing is pale sulphur-coloured.

P. 296, line 17 from above, after *ovata* insert:

rotundata. **Virbia rotundata** Schs., from Castro in the Brazilian State of Paraná, exactly resembles the ♀ of *ovata* (38 c), but the subapical spot on the hindwing is paler yellow and circular.

P. 297, line 15 to 17 from above:

rosenbergi. **Virbia rosenbergi.** This paragraph being repeated by mistake must be eliminated. In typical specimens of *rosenbergi* the black marginal band of the hindwing is strongly widened at the proximal angle, though it does not extend quite so far as in our figure. HAMPSON separates such specimens in which the black band is more prolonged towards the base as **V. phalangia** (= *minuta* Drc. nec *Fldr.*). — As many forms of *Virbia* (*medarda*, *minuta* etc.) are constantly confounded, we suspect them not to be all distinct species.

P. 298, line 12 from above:

Heliactinidia bimaculata Drc., according to HAMPSON, is identical with *Euchlaenidia transcisa* (38 g), the latter name having the priority. — Instead of *bimaculata* insert here:

tornensis. **Heliactinidia tornensis** Prt. (66 m) is almost exactly like *chiguinda* (38 f), but the black marginal band of the hindwing is proximally more irregularly defined and does not despatch before the hind-margin a black ray into the base. Colombia.

Line 20 from above, after *H. flavivena* insert: (66 a).

Line 23 from above, after *H. sitia* insert: (66 a).

Line 20 from below:

tripuncta. Here we might most easily insert a species that was described as *Darna tripunctata* and was thus far placed to the Hypsid genus *Crocomela*, where, however, it does not belong to. Cf. Proc. Zool. Soc. Lond. 1885, pl. 32, fig. 16. This is joined by (*Darna*) **splendens** Drc. (67 c) from Costa Rica. Cf. p. 454, Note, as well as *grandis.* (*Darna*) **grandis** Drc. Similar to the preceding, the yellow costal stripe of the hindwing extends almost to the apex, and a yellow streak from the base to the centre of the wing.

Line 19 from below, after *nigrilinea* insert:

dispar. **H. dispar** Warr. (66 m). Much smaller, otherwise similar to *Eub. rosenbergi* (38 d), but the forewing with yellow veins, the hindwing at the apex broader, but in the radiary ray narrower black; Tucuman. — It was described as *Brachyglene*.

P. 300, line 22 from above, after *H. vestalis* insert: (= *leontei* ab. 3 *Hmps.*).

Line 25 from below: for *H. lumbonigera* read: *lumbonigra*.

Line 16 from below:

daphoena. After (= *pura* Btlr. insert: = *butleri* Dyar. — Another form is ab. **daphoena** Dyar, where the forewing is also above suffused with red or striped along the veins.

nova. Line 4 from below, after „narrowed“ insert: — ab. **nova** Sm., in contrast with *venusta* has light yellow transverse bands.

P. 301 line 14 from above, to *Kodiosoma tricolor* add:

otero. **Kodiosoma otero** Barnes (67 c) is larger, the forewing more uniformly brown with a light transverse stripe behind the centre; from Arizona; it may be a distinct species.

Line 23 from below, after the genus *Kodiosoma* insert:

12a. Genus: **Lafajana** Dgn.

Almost exactly like *Kodiosoma*, but the pectinations in the basal part of the antennae are not so conspicuously shortened as in *Kodiosoma*. One species from Loja is known:

L. cupra Dgn. Body blackish-brown, marked yellow and orange. Wings blackish-brown, in the discal *cupra*. part hyaline; shape and size as in *Kodiosoma otero* (67 c); the legs with a blue reflection.

Line 7 from below:

To the genus *Laora* HAMPSON places yet the species *vivida* Rothsch. (41 h) and *ockendensi* Rothsch. (41 g) listed by us as *Palustra*; cf. p. 324.

P. 303, line 5 from below:

Apantesis elongata Stretch, according to HAMPSON, is not the form *sulphurica* Neum., but the yellow-winged form of *A. blakei*.

P. 304, line 26 from above:

Apantesis figurata with yellow hindwings was named: **pretiosa** Nixon.

pretiosa.

P. 305, line 27 from below:

After *quadrantotata* insert as another synonym to *A. placentia* (= *sociata* B. & Dy.), and after *placentia* insert as one more species:

Apantesis bicolor Hmps. (67 c) from the Bahamas has the forewing quite spotless blackish-brown, and *bicolor*. the hindwing is more fuscous, almost without spots, but the dorsum of the abdomen is broadly black.

Spilosominae.

P. 307, line 18 from below:

Spilosoma kasloa Dyar, according to HAMPSON, is not a distinct species, but a synonym of *Sp. rubra* (39 c).

P. 308, line 14 from above:

In the genus *Maenas* we must eliminate *underwoodi*, the species described as „*Diacrisia*“ *underwoodi* is *Prumala underwoodi* (44 h) p. 345.

Line 16 from above:

(*Maenas*) *ockendeni*, according to recent researches, belongs to *Hypomolis*.

Line 21 from above:

After *Maenas viridis* insert: (66 m).

P. 309, line 22 from below:

For (*Estigmene*) **acraea** read: **E. acraea** Drury (= *acraea auct.*).

acraea.

P. 310, line 4 from above:

After *pudens* add: **Euchaetias cressida** Dyar (40 a) is somewhat similar to *egle*, but larger; from Mexico. *cressida*.

Line 17 from above: to *psara* add: (66 m).

Line 21 from below:

Euchaetias gigantea is presumably only a form of *expressa* (39 g) in which the centre of the abdomen is more intensely dotted; the same is the case with *rhadia* Dyar.

Line 14 from below:

After *castella* insert: (66 m). — The form **Euchaetias griseopunctata** Barnes has the forewings strewn *griseopunctata*. with grey.

To the genus *Euchaetias* we may add another imago described as (*Pericallia*) **pannycha** Dyar (66 m), *pannycha*. shaped like an *E. spraguei* (39 h), but quite blackish-brown. The veins are somewhat lighter, the body and hindwing with a blue reflection; from Mexico, discovered by ROBERTO MÜLLER.

P. 311, after line 7 from above insert:

The following species were yet placed to the genus *Pygarctia*:

Pygarctia grossbecki Davis. Wings as in *spraguei* (39 h), but the head, collar, and abdomen are *grossbecki*. yolk-coloured; from Florida.

- neomexicana*. **P. neomexicana** Barnes (66 m) resembles *expressa* (36 g), but the anterior body is marked whitish-red, and the abdominal part of the hindwing is red as in *perlevis* (39 g). Texas.
- pterostigma*. **P. pterostigma** Dyar (66 m) is similar to *epagoga* (39 f), but smaller, the forewing with a light cell-end spot, and the centre of the hindwing resembling a light spot. Mexico, discovered by ROB. MÜLLER.
- poliochroa*. **P. poliochroa** Hmps. is almost like *murina* (39 g), but the hindwing is of a dingy white, with a narrow darker apical border. Arizona. — Moreover, *murina* is said to be also more correctly placed to *Pygarctia* than to *Euchaetias*, and *albistrigata* B. & McD. probably belongs to them.
- Line 7 from above, to *oslari* Rothsch. insert: (67 d); hindwings pink.
- lorula*. **Pygarctia lorula** Dyar (67 d) from Texas is white, feebly dark-veined, with a purple red hind-head and abdomen.
- flavidorsalis*. **P. flavidorsalis** B. & McD. is like *lorula*, but the frons and abdomen are yellow, as in *alba* (39 f); Texas.
- Line 9 from below:
- After *Hypomolis metarhoda* insert: (67 d); the ♀ recalls *Chlor. rufolivacea* (39 l).
- P. 312, line 1 from above:
- To *Hyp. rothschildi* add: (67 d).
- Line 14 from above:
- After *H. evippus* insert:
- amabilis*. **Hypomolis amabilis** Schs. (67 d) is similar to *H. (Chlor.) rufoviridis* (39 i), but in the forewing there are instead of the commata only dots above the hind-margin and below the costal margin. From Novo Friburgo in South Brazil, discovered by JULIUS ARP.
- Line 21 from above:
- Chlor. thoracica* Rothsch. is not identical with *Chl. rufoviridis*, but it has more yellowish-green forewings, and the hindwings are paler; according to HAMPSON, the species belongs to the preceding genus (*Hypomolis*).
- Line 26 from below insert:
- viridis*. **Chloroda viridis** Drc. is like *rufoviridis* (39 i), but the hindwing is yellow, only in the basal part dusted with red. Peru. — It may be only a ♂-form of *rufoviridis*.
- metamelaena*. **Chl. metamelaena** Dgn. (67 d) is similar to *viridis*, the marginal half of the hindwing is black; from Mt. Tolima in Colombia. Found by A. H. FASSL.
- P. 313, line 4 from above, after *Turuptiana tenebra* insert:
- panoezys*. **Turuptiana panoezys** Dyar (67 e) approximates *tenebra* (39 i), but the black spots on the forewing are still more intensified and enlarged as wedges, but the hindwings are white. Guerrero (Mexico).
- Line 12 from above, after *obscura* insert as synonym: (= *steinbaehi* Rothsch.).
- Line 27 from above:
- To *Turuptiana sanguinea* add: (67 e).
- Line 9 from below, after *Tur. dissimilis* insert:
- fuscescens*. **Turuptiana fuscescens** Rothsch. has the size and shape of *obscura* (39 k), but all the wings are thinly scaled in a dingy earth-coloured grey, the forewing with a yellow costal stripe. Peru.
- P. 315, line 6 from below, after *Ecpanth. atra* insert:
- amulaensis*. **Ecp. amulaensis** Drc. (67 f, g) is similar to the preceding, but the white colour in the forewing more abundant, the hindwing all white, only at the distal margin feebly spotted, abdomen brown. Mexico. — In
- amula*. ab. **amula** Strd. (= ab. 1 Hmps.) the hindwing is black, and the white of the forewing reduced, so that it is very much like *Ecp. atra* (40 c).
- P. 316, line 10 from above, after *E. suffusa* add as synonym: (= *semiclara* Stretch.).
- Line 19 from above, to *E. testacea* add: (67 f).
- Line 22 from above, after *E. testacea* insert:
- obsolescens*. **Ecpantheria obsolescens** Hmps. is similar to *E. testacea* (67 f), but less intensely darkened by brown, more tinted pale yellow, the ♂ hindwing with a longer anal apex. Peru.
- Line 24 from above, after *E. oblecta* insert: (67 e).
- P. 317, line 7 from above, after *E. euripides* insert: (67 e).
- Line 8 from below, to *E. dognini* add: (67 f).

P. 318, line 15 from above, to *Ecpanth. cretacea* add: (67 f).

Line 9 from below, after *Ecpanth. alpha* insert:

Ecpantheria perplexa Schs. resembles *alpha* (40 i), but all the markings are fainter, browner, the costal spots smaller; in the hindwing the abdominal stripe is faded; abdomen brown, lacking the blue lustre, with a yellow dorsal transverse spot. Costa Rica, collected by W. SCHAUS. *perplexa*.

P. 319, line 21 from above, the sentence: „only ♂♂ seem to be known hitherto“ is to be replaced by:

The species is now often stated to occur in Jamaica; food-plants of the larvae: Orange, Vanilla, Ipomoea, Banana, Panicum. — The fact that *eridanus* was produced from the same deposit of eggs proves that it must be regarded as a form of *icasia*. — Egg globular, at the place where it is fastened it is flattened down, with a finely reticulated surface; in the beginning greenish, then steel-coloured grey, with a slight mother-of-pearl shine. Larva in the early stage yellowish, centrally more brownish, with long black hair. Adult larva black, dark-haired; head Indian-red. Its metamorphosis in a web yields a mahagoni-brown pupa of 22 mm (♀) length. It is greatly infested by an Empusa and the Ichneumonid *Eremotylus angulatus* Hooker.

P. 320, line 22 from below, after *Caridartia albicancellata* insert:

Caridartia tenebrosa Dgn. Size and shape similar to that of *albicancellata* (42 b), but both wings in the basal parts less marked in a pale colour, at the distal margin a very highly arched cucullate line. The species also differs considerably in the structure from *albicancellata*, so that the genus *Acyelania* Dgn. has been established for it: Frons with a protuberance, antennae with ciliary bundles; both forewing and hindwing differently veined; still the two species exhibit an alliance. *tenebrosa* was found in Misiones (Argentina). *tenebrosa*.

P. 320, line 14 from below, before *Paracles* insert:

Chlanidophora culleni Brèthes differs from *patagiata* in its larger frontal proboscis; on the forewing the white postmedian area is broader, the black marginal area narrower, the dentate line more distinct. Mendoza in Argentina. *culleni*.

P. 321, line 12 from above, to *Mallocephala deserticola* add: — Larva very variegated with a light brown head, the skin finely watered in a darker colour, on each segment small tufts of dense ochreous hair, out of which single, longer, darker hair protrude. Before each hair-tuft a blackish transverse band, all of which are traversed by a broad, yellowish-white dorsal line and 2 similar subdorsal lines. At the anterior and posterior ends the hairs are somewhat longer but do not form pencils. On low plants; it pupates about Christmas time and yields the imago in January and February.

P. 321, line 26 from above, after *Mallocephala magna* insert:

Mallocephala peruensis Dgn. resembles *magna* (41 d), but the abdomen and the hindwing at the apex and hind-margin are soot-coloured brown. Cuzco (Peru). *peruensis*.

P. 321, line 23 from below, insert after *deserticola* (41 b): „of which it seems to be merely a greyer form, as well as **bogotensis** Dgn. from Bogotá an earth-brown form“. *bogotensis*.

P. 321, line 8 from below, add to *vulpina* Hbn.:

Of the ♂ of this species the ♂ described as *A. felderi*-♂ is only a smaller form; *felderi*-♀ = *nitida* Jones-♀.

P. 321, line 3 from below, to *Antarctia lehmanni* add: (67 g).

P. 322, line 6 from above, insert:

— **cajetani** Rothsch. has a more dark red-brown ground-colour of the forewing, the hindwing is lighter, towards the margin shaded with a dark red; from Montevideo. *cajetani*.

P. 322, line 7 from above, to *Ant. vulpecula* add: (67 g).

Line 20 from above, after *A. fervida* insert:

Antarctia quadrata Rothsch. is very similar to *fervida* (41 c), but the body and wings are dark soot-brown. Sapucay (Paraguay). *quadrata*.

Line 25 from above:

A. venata Schs. is the ♂ of *surgens* Wkr. The figure of *surgens*-♂ on pl. 41 h represents a much-flown specimen (perhaps of *pallidivena*?). — After *surgens* insert:

A. flavescens Schs. (67 i) is uni-coloured dull white, with slightly darker veins. South Brazil. *flavescens*.

P. 322, line 21 from below, to *Ant. gigantea* add: (68 h).

P. 323, line 1 from above, to *A. thursbyi* add: (67 g).

P. 323, line 9 from above: *multifarior* differs from *fusca*, and is not synonymous. Of *multifarior* the ♂ has whitish hindwings but narrowly edged with a dark colour, and the ♀ has a thick black dot in the centre of the cell of the forewing, and a dark stripe before the marginal area.

Line 18 from above, after *marmorata* insert:

tolimensis. **Ant. tolimensis** Dgn., from Colombia (San Antonio), resembles *marmorata* (41 f), but instead of the dark spots there is in the forewing a dark postmedian stripe.

Line 25 from above, to *reversa* add: (67 g).

Line 23 from below, to *pectinalis* add: (67 g).

Line 18 from below, after *cnothocampoides* insert:

uniformis. **Antarctia uniformis** Jones is similar to *vivida*, the forewing with a distinct cell-end streak, hindwing more uniformly yellow, not darkened at the margin; Castro (Paraná).

P. 325, line 1 from above: *juruana* (♂) and *Antarctia klagesi* (♀), according to HAMPSON, the two sexes are of one and the same species; the name *juruana* has the priority.

Phaegopterinae.

P. 327, line 2 from below, to *flavinigra* add: (67 h).

Line 1 from below, after *Cyanarctia flavinigra* insert:

percurrens. **Cyanarctia percurrens** Warr. is smaller, the orange band of the forewing equally broad; it resembles some *Diopitidae*, such as *Josiadena* Bsd. (71 g), and also some ♀♀ of *Aricoris*, *Lymnas* etc. Peru.

basiplaga. **Cyan. basiplaga** Fldr. (= *lithosiaphila* Dyar) (39 l. as *Cisthene abdulla*). Black, basal half of forewing orange; from Mexico. Cf. p. 467, under *abdulla*. — **carpintera** Schs. from Costa Rica is the same, the margin of the orange area of the forewing slightly curved.

P. 328, line 15 from below, after *Diospage semimarginata* add: (67 h).

P. 329, line 16 from above, after *Belemniastis troetschi* insert:

eucyane. **Belemniastis eucyane** Fldr., from the Amazons, rather exactly resembles *Napata banghuasi* (21 d), but the median oblique band of the forewing is below more pointed, the red spot on the hindwing larger, the anterior body with small white dots.

Line 22 from below, to *Metaxanthia vespiformis* add: (= *auranticauda* Klag.).

aureiventris. — **aureiventris** Rothsch. from Costa Rica is almost exactly like *vespiformis*, but the apical parts of both wings are more darkened. — **atribasis** Rothsch. has only the 2 first abdominal rings black, otherwise the whole abdomen is orange; Ecuador.

P. 330, line 20 from above, after *metaxantha* insert:

binotata. In **Glaucostola binotata** Schs. the forewing is like in *metaxantha*, but the hindwing has in the ♂ but little black at the apex, whilst in the ♀ the black marginal band extends to the posterior angle; Guiana; likewise similar is **maroniensis** Joic., also from Guiana (St. Jean de Maroni), in the cell of the forewing a faded grey streak and similar ones between the veins of the distal-marginal half; in the hindwing the costal area is lighter yellowish, the marginal band towards the apex duller.

P. 331, line 14 from above, insert:

HAMPSON has recently placed to the genus *Baritius* the *Loxozona acuminata* Wkr. of p. 143.

peculiaris. Line 15 from below: for **B. peculiaris** read: **B. hampsoni** Dgn. (= *peenliaris* Rothsch.) (67 h).

Line 19 from above, after *B. pyrrhopyga* insert:

palmeri. **Baritius palmeri** Rothsch. from West Colombia is quite similar to *pyrrhopyga*, but the abdomen is without red, only the last segment narrowly honey-coloured.

P. 332, line 7 from above, after *Baritius eleutheroideis* add: (67 i).

Line 13 from above, after *Baritius affinis* add: (67 k).

Line 3 from below, after *S. russa* add: (67 i).

P. 333, line 2 from above, at the end of *Syntarctia* insert:

Syntarctia uniformis Rothsch. (67 i) is honey-coloured with diaphanous white hindwings, not dissimilar *uniformis*. to certain *Halisidota* of the group of *H. flavescens* (59 i) and for that reason described as *Halisidota*; from Guiana.

Line 3 from above: To *Tricypha* a lepidopteron is placed which was described as *Elysius* by ROTHSCILD:

Tr. pseudotricypha Rothsch.; somewhat like *Tric. imperialis* (42 i), but the head is whitish, the transverse shade *pseudotricypha*. of the forewing is differently placed, encircling the cell-end like a ring; from Guiana.

Line 18 from above, at the end of *Tricypha* insert:

Tric. ochrea Hmps. (67 k) is not dissimilar to a *Bituryx minuta* (55 e), but in the disc of the forewing *ochrea*. there are several black punctiform spots. South Brazil.

Tric. mathani Rothsch. is quite similar to *ochrea* (67 k), but instead of yellow it is of a dull reddish grey, *mathani*. and the dark dots have shaded off into dull small spots. Colombia.

Tricypha proxima Grt. (67 k) is larger than the preceding, of a dull sooty black with a yellow abdomen. *proxima*. From Cuba.

HAMPSON besides inserts his *Atyphopsis obscura* (= *Bituryx hoffmannsi* Rothsch.) (21 b) in the genus *Tricypha*; cf. p. 138.

Line 18 from below, to *Hypocrisias gemella* add: (67 i).

Line 13 from below, after *Hypocr. gemella* insert:

Hypocrisias velivolans Dyar. Forewing straw-coloured, rather densely strewn with a dark brown, *velivolans*. so that a basal and a discal heap of spots are indistinctly visible, whilst 2 distal rows are more distinct. Hindwing shaded with dark brown, particularly along the hind-margin, the veins bordered with a light tinge. The wings are broad as in *punctata* (42 i); but the spots are coloured like the ground, not whitish. It is the most similar to *gemella* Schs., though the latter is decidedly tan-coloured and shows the two distal rows of spots more bent, irregular, and the rows more separated. Mexico City, found by ROBERTO MÜLLER in June.

Line 1 from below, add yet to the genus *Hypocrisias*:

Hypocrisias bombycina Rothsch. Pale yellowish-red; abdomen above yellowish-grey, at the base a *bombycina*. rosy tinge. Forewing very light yellowish-red, with traces of a dull postmedian shade being inwardly bent below vein 4, and of a subterminal shade which in the centre is distally bent. Hindwing semi-transparent, with a yellowish tinge. Expanse of wings: 46 mm. Peru.

P. 334, line 1 from above, add:

To the genus *Tessellarctia*, according to HAMPSON, belongs also *Tessell. klagesi* Rothsch. (53 i) described as an *Ammalo*. Cf. p. 385.

Line 20 from below: after *Ochr. marina* add: (67 i).

P. 335, line 12 from below, to the genus *Carathis* add:

Carathis melamera Dogn. is almost exactly as *Aemilia rubriplaga* (43 c), but the light spot in the centre *melamera*. of the forewing exists only in its costal and hindmarginal parts, and the hindwing is at the apex broadly yellow. São Paulo (Brazil).

Car. tabaconas Joic. is much smaller, chocolate-brown, the base of forewing is yellow mixed with *tabaconas*. orange; in the centre of the cell a pale yellow round spot, and a similar one with an orange border at the cell-end. Between veins 6 and 8 a light spot with 2 dark punctiform spots in it, before the distal margin small yellowish spots. Hindwing whitish hyaline; at the hind-margin slightly haired rosy. Peru.

Line 1 from below, add to the genus *Neozatrephes*:

N. schausi Rothsch., described as *Baritius* and listed by us on p. 332 as *Bar. sch.*, is placed here by *schausi*. HAMPSON.

P. 336, line 17 from above, to *Dialeucias violascens* add: (67 i).

Line 20 from below, after *Hyperthaema sanguineata* insert:

Hyperthaema sororita Schs. is allied to *haemacta* (43 c), larger, below the proximal, white-centred *sororita*. small spot there is another smaller one which is sometimes confluent with it. Guatemala.

Hyperthaema excuintla Schs. Likewise from Guatemala, smaller than *sororita*, the forewing browner, *excuintla*. the small spots almost extinct, the hindwing black, at the hind-margin somewhat rosily haired.

Line 6 from below, add to the genus *Hyperthaema*:

Hyperthaema perflammans Hmps. is almost like *sanguineata* (43 c), but of a more glaring red, the *perflammans*. forewing more distinctly dark-veined, the two white spots larger; Ecuador, Peru.

Hyperthaema reducta Joic. is just as large as *perflammans*, the forewing more purple red, the white *reducta*. of the centre of the hindwing behind the cell-end expanded into a spot. In the ♀ the distal white spot may also be absent. Colombia.

P. 337, line 6 from above, for *Ardanikla* read: *Ardonipsa*.

P. 338, line 12 from above, for *spracosiae* read: *syracosiae*.

Line 20 from above, to *Aemilia* add:

HAMPSON lists yet in this genus *affinis* Rothsch. (42 k) described as *Carathis*, and besides there has recently been described:

carmen. **Aemilia carmen** Schs. 35 mm. Forewing diaphanous whitish-grey, costal margin and hind-margin whiter with dark brown transverse markings, near the base a line, before the centre a band flawed in the cell. A broad costal stripe in the centre, and a square spot at the hind-margin. The veins are partly marked dark. Hindwing diaphanous whitish-grey. Guatemala.

P. 341, line 18 from below: for *Joisey* read *Joicey*.

Line 10 from below, to the genus *Melese* add:

sotrema. **Melese sotrema** Schs., from Guatemala, has a brown head and thorax, intermixed with reddish hairs, posteriorly shaded with grey; abdomen pink. Forewing reddish-brown, between veins 5 and 6 a minute light hyaline spot. Hindwing diaphanous whitish, bordered with pink. Forewing beneath with a black longitudinal groove below the cell. Expanse of wings: 37—42 mm.

P. 342, line 4 from below, to the genus *Bertholdia* add:

flavilucens. **Bertholdia flavilucens** Schs. Head and thorax mouse-coloured, with yellow markings, abdomen above purple pink. Forewing lilae-grey irrorated with black, in the cell and behind the hyaline reflection with a rosy tinge. Fringes slightly speckled. At the base as far as the centre of the wing above the cell a greyish streak; the reflecting spot with few small vein-dots, between 7 and 8 slightly sinuate, from 7 to 6 straight, from 6 to 3 thrice distally bent, then parallel to vein 3 and slightly inverted to vein 5. Above the submedian there is a minute spot encircled by black. Hindwing white, in the hind-marginal area with a pink hue. Expanse of wings: ♂ 44, ♀ 55 mm.

P. 344, line 4 from below, to the genus *Robinsonia* add:

mossi. **Robinsonia mossi** Rothsch., from Pará, is white, the wings diaphanous, forewing with a mouse-coloured apical fifth and costa, and white veins. Palpi, frons, and vertex yellow. Expanse of wings: 40 mm.

P. 349, line 1 from above, insert:

Automolis luteola Rothsch. is placed as synonym to *Idalus xanthia*.

Line 5 from above: for *flavobrunnea* read *flavibrunnea*.

Line 12 from above, after *Idalus flavoplaga* insert:

flavithorax. **Idalus flavithorax** Joic. resembles *flavoplaga*, but the abdomen above is yellow except the 3 last segments; ground-colour of forewing more tinted reddish; expanse somewhat larger. South Brazil.

P. 351, line 15 from above, to the genus *Amaxia* add:

tierna. **Amaxia tierna** Schs. has about the size of *consistens* (45 e); forewing yellow, at the base of the costal an interrupted purple stripe; before the centre steel-grey costal streaks, similar ones in and below the cell; the lowest streak is followed below vein 2 by a round spot connected with a yellow spot by a grey circular line. Beyond the centre a series of grey internerval spots, similar ones at the margin. Hindwing pink with a whitish costal margin and partly semi-transparent streaks; beneath the hindwing is violettish-pink, the round central spot is purple. Guatemala.

carinosa. **Amaxia carinosa** Schs. is smaller than *tierna*, the violettish-brown basal part is intermixed with yellow spots, before the margin a series of large purple spots narrowly edged with dark brown and only separated by purple vein-streaks. Hindwing pink, at the costal margin white, a marginal part shaded with black. Guatemala.

P. 355, line 9 from below, after *Paranerita polyxenus* insert as a synonym: (= *garleppi* Rothsch.).

P. 356, line 22 from above, after *Paranerita peruviana* insert:

irma. **Paranerita irma** Schs. Size and colouring similar to *peruviana* Rothsch. (46 a), but the yellow marginal spots are smaller and differently shaped, all are bordered with purple, the lower margin of the larger yellow costal spot is rounded in the centre of the forewing; a larger yellow spot near the apex. Hindwing yellow with slight pink hairing. Guatemala.

P. 359, line 5 from above, to *repanda* add: Also from Venezuela.

P. 360, line 20 from below, to the genus *Neritos* add:

discobola. **Neritos discobola** Hmps. is very similar to *repanda* (46 d), but the apical circular spot is much farther remote from the violettish-brown basal half of the forewing, the border of the yellow colour and the basal violet colour being irregular. Somewhat larger than *repanda*.

Neritos atta Schs., according to the description which does not specify the under surface, seems to *atta*, resemble *sardinapalus* (46 f), exhibiting, like the latter and most of the *Neritos*, a purple-violet basal half and apical disc in a yellow ground, though considerably smaller; expanse only 24 mm; from Guatemala.

Neritos cucufas Schs. is about the size of *ockendeni* (46 f), but differently marked; ground-colour *cucufas*, tan-brown, with maize-coloured spots: a large one from the centre of the costa, being slightly strangulated at the subcostal, then regularly rounded, as far as below the cell to the submedian; a small spot at the apex, another one at the distal margin. Hindwing tan-coloured. From Tumatumari in British Guiana.

Neritos cybar Schs., from Tucuman in Argentina, is considerably smaller than *cucufas*. Ground- *cybar*, colour of forewing cinnamon-brown, the yellow spots tan-coloured, bordered with red, in the central third of the costa a large, maize-coloured spot; hindwing cream-coloured.

P. 361, line 18 from above, for *tramoia* read *hamoia*.

P. 362, line 12 from above, to the genus *Parevia* add:

Parevia vulmaria Schs. has the size of *P. parnelli* (46 k), the forewing is violettish-brown, with yellow *vulmaria*, markings, but the hindwing light coralline, the costal margin and fringes dark yellow. Rio de Janeiro.

Parevia gurma Schs. is one of the smallest species of the genus, not larger than *methaemia* (46 k). *gurma*. Forewing with yellow spots contrasting with the ground-colour by their dark brown and dark borderings. Hindwing at the base and hind-margin pink, the distal margin broadly black. From Guatemala.

Line 6 from below: for *Schallotomis* read: *Schalotomis*.

P. 363, lines 7 to 3 from below:

The paragraph on *Antaxia abdominalis* H.-Schäff. is to be cancelled; cf. the footnote on p. 370.

P. 367, line 22 from above, after *Automolis nabdalsa* insert:

Automolis postradiata Schs. Size of *Eupseudosoma involuta* (50 a). Wings orange, hindwing with *postradiata*, some black veins and a black radiary spot before the hind-margin. Colombia.

P. 375, line 12 from below: for *leucopera* read *leucopera*.

P. 376, line 20 from above: for *pandiona* Rothsch. read: *pandiona* Cr.

Line 9 from below, at the end of the genus *Automolis* add:

Automolis asteroides Schs., from French Guiana, is rather a small species (expanse of wings: 30 mm) *asteroides*, with a whitish-yellow thorax and a brown, laterally purple-spotted abdomen. Forewing white, darkened with brownish; forewing with white dots at the base; the brown basal part of the forewing with light streaks, the distal part of the forewing in its costal half very pale yellow with brown veins. Hindwing white, darkened with brownish.

P. 378, line 18 from below, for *bicolorata* Rothsch. read: *bicolorata* Drc.

P. 382, line 23 from above, to the genus *Phaeomolis* add:

Phaeomolis ochreogaster Joic. Head, thorax, and abdomen white, above except the base of abdomen *ochreogaster*, slightly tinged ochreous; palpi tinged brown, chest and legs white. Forewing uni-coloured silvery white. 40 mm. Sapucay (Paraguay).

P. 384, line 29 from above, to *Ammalo* add:

Ammalo eglenensis Clem. is incorrectly listed here, according to examinations by BARNES and MC DUNNOUGH, as a consequence of this form having been mixed up with *inopinatus* Edw. Its correct position would be at *Pygarcia* (p. 310).

Line 20 from below, for *Amm. aravaca* read: *aravaca*.

Line 1 from below, after *Ammola constellata* insert:

Ammalo ramsdeni Schs. was recently described from Cuba. It has the size of *eglenensis* (53 g). Forewing *ramsdeni*, brownish-yellow, light yellow and black, with very bright and varied markings, so that the insect resembles more an *Eucereum* (pl. 24 and 25) from the family of the *Syntomidae* than an *Arctiid*. Hindwing brown, a spot in the cell and another below it are semi-transparent.

P. 386, line 20 from above: for (*Elysium*) *midiofascia* read: *mediofasciata*.

Line 23 from below, after *Elysium magnifica* insert:

Elysium macasia Schs. is a large species approximating *cingulata* (54 a) and *magnifica* (54 a), but the *macasia*, colouring and marking are almost as in *Mazaeras conferta* (53 h) of which it has also the size. Ecuador.

ruffin. **Elysium ruffin** Schs. is somewhat like *sebrus* (54 b), though smaller, the forewing more brightly coloured orange, the antemedian band strangulated in the submedian fold where it is broad in *sebrus*. Hindwing white suffused with flesh-colour. From Petropolis (Brazil).

P. 387, line 5 from above, after *pyrosticta* insert:

gladisia. **Elysium gladysia** Schs. from Guatemala has a light ground-colour with ruddle-red markings, similar to those of *E. pyrosticta* (53 i), though the species is much larger, as large as *E. conjuncta* (54 c).

P. 390, line 24 from above, after *Pel. pallida* insert:

nabor. **Pelochyta nabor** Schs. is smaller than *pallida* (55 b), the forewing wood-coloured brown with rust-coloured markings; an oblique band from the base of the costa, a transverse band before and behind the centre, at the cell-end and directly behind it a blackish-brown spot. Hindwing white. Peru.

P. 391, line 9 from above, after *Agoraea longicornis* insert:

santaria. **Agoraea santaria** Schs. resembles *longicornis* (55 d), but it has a browner tinge, with much less intensely marked veins, and the hindwings are also more scantily scaled. Expanse: 35 mm. Guatemala.

rulla. **Agoraea rulla** Schs. is similar to *santaria*, smaller, the wings more brownish-grey with somewhat more lilac reflection, the disc of the hindwing opalescent. Likewise from Guatemala.

P. 394, line 19 from above, to *Ischnocampa rosenbergi* add:

rosenbergi. **I. rosenbergi** (= *nitens* Schs.). — The form **roseitincta** Schs. has a broader black dorsum of the abdomen, *roseitincta.* so that the yellow lateral spots are greatly reduced. In the hindwing the hyaline disc beneath is discoloured light pink which shows through above. Costa Rica.

P. 399, line 20 from below, after *Opharus chorima* add: (= *catarhinae* Rothsch.).

P. 403, line 4 from below, to *Halisidota annulosa* add:

Larva with a rounded head which is broad, lustrous, middle suture and V-spot whitish. Body light yellowish, without spots; hair dingy white, in dense straddling tufts. Two fine black pencils on each side of the 4th segment, a single pencil on ring 12, and some few black subdorsal hairs on ring 13 which exhibits a black angular spot also above. Misantla (Mexico).

P. 404, line 27 from above, for *endalobota* read: *eudolobata*.

P. 406, line 14 from above, after *Halisidota coniota* insert:

agatha. **Halisidota agatha** Schs. Size of *longa* (58 a). Antennae with long, light brown pectinations. Forewing blackish-brown, costal margin and fringes tan-coloured, hindwing light tan-coloured, towards the margin very brownish; at the transverse vein a dark line. Abdomen above blackish-brown. Bolivia.

P. 408, line 25 from above, after *H. cedon* insert:

valentina. **Halisidota valentina** Schs. Size and shape of *cedon* (58 f), but behind the centre a row of ochreous spots, the postmedian spot between veins 5 and 6 larger, with a dark nebulous stripe to the apex; above the discocellular an ochreous tan-coloured streak at the costa. From French Guiana.

P. 410, line 2 from above, before *H. tanomo* insert:

orooca. **Halisidota orooca** Schs. is similar to *lineata* (58 i), somewhat smaller, the black scaling of the honey-coloured forewing groups round the cross-vein forming rather dense nebulous spots; the dark median longitudinal line terminates behind the cell-end, and on the submedian there is likewise a blackish longitudinal line, like in the form *rosetta* (58 h). From Tucuman in Argentina.

dinora. **Halisidota dinora** Schs., likewise from Tucuman, is much larger than *orooca* (expanse 44 mm), the forewing white, tinted with tan-colour, the markings blackish-brown, at the base an orange spot. The veins are also blackish-brown; from the centre a double row of partly extinct rings; the median ringlets are larger at the costal margin and smaller towards the hind-margin. Hindwing white, before, in and behind the centre as well as at the distal margin dark lines; the veins are also dark.

ephoem. **Halisidota ephoem** Schs. Size of *rosetta* (58 h). Ground-colour tan-coloured, the veins cinnamon-brown like the transverse markings. Through the cell extends a fine dark line, at the costal margin minute black spots, along the submedian there extend longitudinal lines to the postmedian line; below the subcosta two curved lines in the cell. Hindwing white, thinly scaled. Bolivia.

P. 412, line 7 from above, for (*Halisidota*) *harrisi* Pack. read: *harrisi* Walsh.

P. 420, line 3 from above, after *Amastus alsa* insert:

vandregisili. **Amastus vandregisili** Schs. is as large as *pseudocellaris* (48 b) which it approximates according to its author, but the abdomen above is more orange-red; on the forewing the postmedian transverse nebulous stripe and the dark marginal band leave a narrow line of the ground-colour between them. From Ecuador.

Pericopinae.

P. 446, line 3 from below:

As *Are mummia* Cr. (46 e), by mistake, an Agaristid has been inserted here, which is described in Vol. 7 (p. 10) and figured there on plate 1 g in the male sex. This paragraph must therefore be eliminated here.

Alphabetical List

with reference to the original descriptions of the forms of the American *Arctiidae*.

* signifies that the form is also figured at the place cited.

5. Family: Dioptidae.

This family containing about 500 lepidopteral forms has gone through many and continual changes with respect to its systematic insertion as well as to its composition. (For further particulars see p. 501.) Even to-day the synopsis, having been founded on the following statements, cannot be regarded as being final and unalterable. PACKARD who, though not felicitously, founded his systematic observations upon the pupae *), reminds us of the congruity of neurations between the Dioptid *Phryganidia* and Geometrid genera, such as *Melanchroia*, which, by the larvae, have been proved to be genuine *Geometrae* (DEWITZ). The Dioptid pupa exhibits such a striking resemblance to that of *Cleora* that PACKARD is induced to insert the *Dioptidae* in his pedigree **) between the *Cylopodidae* and the genuine *Geometridae*. The greatest confusion in trying to insert the *Dioptidae* was created by their wrong composition, since entirely heterogeneous elements were coupled together in quite an unnatural union.

As may easily be gathered from the introductory words on p. 501, the mimicry chiefly caused this confusion, because even expert specialists confounded mimetic resemblance with phyletic resemblance. Nowadays we are fully aware in what complete way mimicry is able to conceal real relations and to put forth specious ones. This fact is particularly evidenced by the study of the living insect which, on being observed in its surroundings, by its behaviour reveals its true relationship to similarly coloured lepidopteral allies. The *Dioptidae*, as is stated below, are frequently diurnal insects, partly swarming in the sunshine (*Dioptis*), partly being very easy to rouse, and flying very skilfully and safely in the day-time (*Josia*, *Phaeochlaena*), but sometimes also coming to the lantern in the night. The flight of the single species is entirely different and no less subject to the mimetic influence than the colouring of the insect is. The *Dioptis areolata* which does not copy any certain model, exhibits a whirling, swaying flight, like the unprotected day-fliers *Orgyia antiqua* or *Drepana cultraria* (and like nearly all the unprotected *Heterocera* flying in the sunshine have), which makes it extremely difficult to capture them with the net in the air, for instance a *Bupalus piniarius* or *Lymantria dispar*-♂; in contrast with them, the *Scea auriflamma*, many *Myonia* and the variegated *Getta* exhibit the straight flight of their models, which are protected as *Pericopinae* or *Arctianae* by a very odoriferous oil ***) and have a rather rectilinear flight, such as the *Arctiidae* of all regions flying in the day-time, the *Coscinia*, *Utetheisa*, *Rhyparia*, *Callimorpha* etc., which partly fly onwards in an entirely straight line, partly only slightly flutter in their flight. Those Dioptids, copying protected butterflies, fly exactly according to their models, as for instance *Dioptis phaedima* (70 c), which exactly copies the Danaid *Hypoleria egla* or *aureliana* (vol. V, pl. 41 a). In *Josia ligula* and *ligata* reproducing together with the Erycinid *Mesenopsis* the colouring of numerous *Arctiidae* the resemblance in flying is so strikingly deceptive that, according to A. H. FASSL's statement, the Erycinid and Dioptid are not at all discernible when flying, and in settling down only by the Erycinid flying off more timidly than the Dioptid.

The position of the *Dioptidae* has been rendered more intelligible by obtaining better — though still very scanty — knowledge about some of their larvae. The ventral feet on the middle segments have proved the independency of the group from the Geometrid tribe (which, however, is contested by PACKARD, who does not attach great weight to this fact *). Meanwhile, however, the larva of *Phaeochlaena gyon* has been made known by MABILDE, and has resulted in showing an unmistakable resemblance with the larvae of certain *Notodontidae*, as already the larva of *Phryganidia californica* by its bareness and its anal protuberance reminds us of the *Notodontid* genus *Pheosia*.

The original appearance of the imagines of *Dioptidae* can the less be guessed nowadays as the uncommonly vast mimicry assimilating the species with the most heterogeneous models has scarcely left any traces of the original type. The principal groups from which the models are taken, are mentioned on p. 501, and it seems that their frequently very contrary colourings in some Dioptids have necessitated a rather incisive dyeing-

*) Journ. New York Entomol. Soc. 1895, p. 30.

**) American Naturalist 1895, p. 803.

***) The scent of these models is somewhat like that of the *Zygæna*, thus similar to that produced by triturated or crushed *Coccinella*.

and presumably also transformatory process. It may be that the markings and colourings that are to-day yet exhibited in the polytypical genera *Polypoetes* and *Tithraustes* represent the original appearance of the family the original types of which may besides have been of a rather small size; at least about 80 per cent. of all the species known have an average expanse of only 3 to 4 cm; but very few species (*Phaeochlaena integra* and *Phanoptis cyanomelas*) exceed this by attaining about 6 cm expanse.

Most of the *Dioptidae*, particularly the species belonging to the genera *Tithraustes*, *Polypoetes*, *Scotura*, *Dioptis*, *Euchontha*, *Stenoplastis* etc., owing to their insignificant exterior, could not rivet any particular attention with the enormous legion of average collectors, the less so since they are generally met with at the habitats of the most beautiful and imposing lepidoptera of the globe. Most of the species were — not only by laymen — valued as small Geometrid species, and only the more conspicuously variegated *Myonia* and *Josia* are found to have been taken more consideration of in older works, and even in the old trading catalogues there are mostly only forms mentioned which are allied to the latter. The fact that PROUT, who wrote the catalogue mentioned below was the first monographer on this difficult and mimetically confused family evidently shows how much it was neglected. Besides, however, some *Dioptidae* are also in the habit of flying about 2 to 3 m above the ground and of escaping up into the air on being pursued, as in Europe the *Drepana cultraria*, so that it may often be very tiresome to pursue them in disadvantageous districts; and furthermore, those species flying in the daytime most exceptionally come to the lantern. In some, such as many *Dioptis* (*pallene*, *incerta*, *cyma*, *illerdina*, *egla* etc.), the mimetic resemblance with the models from the families of the *Danaidae*, *Syntomidae* etc. swarming in large numbers at their habitats is so striking that even experts have great difficulty in discovering the imitators. Among the very numerous species wearing for instance the colours of *Josia ena Bsd.*, and among which there are *Erycinidae*, *Arctiidae*, *Syntomidae*, *Geometridae*, and numerous microlepidoptera, we find but very few of the *Josia* themselves, and it is easily understood that only by intensely and carefully collecting them they may be brought in in numbers. The *Josia* here frequently play the same part among the *Heterocera*, as for instance the genus *Napcogenes* does among the *Rhopalocera*, where likewise the immense frequency of the models often diverts our attention from the imitator.

Yellow bands on a jet-black ground is the predominant colouring of the mimetic genera; but since presumably all the *Dioptidae* are good flyers — partly even never resting and indefatigable flyers — their marking is not so subtle as we have noticed in many less intensely flying families, such as *Erycinidae*, *Ithomiinae*, or *Heliconiinae*. Specimens of *Monocreagra pheloides*, for instance, captured at the same clearing of a forest, may differ from each other so much that the white subapical spot of the forewing may attain treble the size and quite a different shape from what it usually has; it may be snow-white or also light hyaline, band-shaped or oviform, coherent or divided; the hyaline areas may be distinctly bordered or also die away at their borders, and the size of specimens from the same district may vary so much that they may be much larger than the figure (70 d) or also half its size. The same variability is found in the *Dioptis restricta* (69 l), and among a great many specimens of *D. arcolata* all of which I collected at the same habitat and season near Santos there are not even two exhibiting the same size of their hyaline areas.

The sexes of the *Dioptidae*, as a rule, do not exhibit any difference of the exterior, but in a number of species the ♂♂ are distinguished by scent-organs which may sometimes most conspicuously alter the shape of the wings. For instance in the ♂ of *Sagaris rejecta* (71 i) the anal margins of the hindwing are doubled up into a fold in which there is a layer of hairs 1 to 2 mm long, which are whitish at the upper edge of the fold and black at the margin of the wing. In *Sagaris dilatata*-♂ (71 k) there are on the sides of the 4th to 6th abdominal rings dense brushes of coal-black hair, and in the ♂ of *Polyptychia fasciculosa* (cf. the figure of *ceron* 71 k) we notice a still more complicated organ which even gave rise to the denomination of this strange species: on the thickened hind tibiae there are long white tufts of fine, slightly bent, silky hairs. The hind-margin of the hindwing exhibits a similar yellowish lock of coarser hairs, and besides the hindwing shows below the lower wall of the cell a deep skinny depression from the ground of which an extensible pencil sticks out. Under the microscope all these hairs prove to be circular fine bristles without sharp points or barbs, so that they are actually to be regarded as scent-organs and not protective organs.

All these facts prove the *Dioptidae* not to be related to the preceding *Arctiidae*, but rather to belong to one group with the hereafter following families of the *Drepanidae* or also the *Notodontidae* from which they show forth by the altering effects of mimicry in a similar way as the *Ithomiinae* from their relations of the *Danais*, *Hestia*, and *Euploea*. But before the family is definitely ranged, we have left it for practical reasons at the place where it is used to be looked for in the catalogues thus far existing, and we merely refer here to its presumptive position in the system.

Dioptidae.

There is probably no family that opposed such great difficulties to the specialists of former times, as the *Dioptidae* did. Their exterior very easily led to mistake them for others, and it is therefore not to be wondered at that the members of this group of lepidoptera were listed in the most diverse families. Some of them have been described as Arctiids, others as Geometrids, and others again in Syntomidid genera. Some species were even placed to the Psychids, such as *Phryganidia*. Later on the Dioptids were comprised with the Geometrids of the allies of *Cyllopoda* in the Cyllopodids. It was only in 1918, when PROUT (Novit. Zoolog. 25, p. 395 seq.) undertook a thorough revision, in which a table for ascertaining the genera was given and all the species were catalogued; we have, on the whole, followed PROUT's revision in the present work.

If we regard the various forms of the *Dioptidae*, we find resemblances to the most diverse families. *Phaeochlaena* and *Myonia*, by their blackish-yellow species, recall *Cyllopoda*; *Myonia cingulina* exhibits a striking resemblance with the Syntomidid *Microgiton submacula* Wkr. (36 f), while other species of the genera resemble Pericopids and Heliconiids. *Myonia basivitta* resembles the Arctiid *Euryptidia basivitta* (36 f); the lustrous blue species with hyaline areas are like corresponding Syntomidids (*Agyrta* and others), *Tithraustes* and *Polypoetes* look like small Geometrids, *Phanoptis* is hardly discernible from the Geometrid *Locha*; the species of *Diopsis* so much resemble the *Ithomiinae* that BATES was led to his theory of mimicry; the same design of marking and colouring is also exhibited by the Pericopine genus *Hyahurga*; *Scea* has images among the *Pyrallidae* and *Pericopinae*, and *Sagaris* among the *Agaristidae*. The species of different genera also resemble each other, as for instance species of *Myonia* appear in the exterior of *Josia*-species.

All the *Dioptidae* are neotropical except the Californian *Phryganidia californica*. A great part of the species, at least those with bright colours, seem to fly in the daytime. A striking fact is the prevalence of the blackish-yellow colourings. As to the larvae, little has become known; that of *Phaeochlaena gyon* F. was described more minutely. It lives on *Aristolochia lactea* and is slender, with an oblique, cordiform head, light yellow, with three red dorsal stripes and a red spot on the last segment. Four pair of normal ventral feet are present, the hind feet are, as in the larvae of our pussmoth (*Harpyia vinula*), transformed into two projecting anal appendages. The pupa is spun together between two leaves or in an inverted leaf; it is reddish-grey with darker spots. The structure of the larva evinces that the *Dioptidae* have nothing to do with the *Geometridae*, but are to be placed to the allies of the *Notodontidae* or *Drepanidae*.

As the members of the family are often extremely similar to the representatives of other families, some principal differences are to be pointed out here. All the *Dioptidae* lack the analis (vein 1 c) in both wings, by which mark they can be separated from similar *Pyrallidae*; in the latter, moreover, mostly the subcosta (vein 8) of the hindwing is fused with the anterior edge of the cell. The 2nd median vein is situated midway between the 3rd and 1st median veins, or nearer to the 1st. In similar *Pericopidae*, *Syntomidae* etc. the 2nd median vein is nearer to the 3rd. Most of the forms, however, resemble *Geometridae*; but in the latter there is at the base of the abdomen a large, laterally open tympanal organ which lacks the *Dioptidae*; in the latter, moreover, the subcosta as far as the base is almost parallel to the anterior edge of the cell in the hindwing, whilst in the *Geometrids* it makes yet very close at the base a large bend which is anteriorly convex. The hind tibiae always have two pair of spurs, the tongue and frenulum are well developed.

1. Genus: **Phaeochlaena** Hbn. (*Campylona* Mschlr., *Neolaurona* Drc., *Clastognatha* Fldr.).

In the forewing the 2nd radial vein rises from the cell; the 1st cubital vein likewise rises from the cell; in the hindwing the 1st cubital vein and the 3rd median vein rise separately. The species are all marked black and yellow or brown.

Ph. gyon F. (68 a). Wings dark brown, basal area indistinct, a discal band more distinct and the veins partly yellow in the forewing, a subapical spot yellow or white. Hindwing with a yellow central area. — In the typical *gyon* F. (= *tendinosa* Hbn., *remota* Wkr., *obtecta* Mschlr.) the discal band is rather distinct, the subapical spot white. — The form **ochrophanes** Prt. has broader yellow markings, the discal band terminates posteriorly in a clear yellow spot. — In **dorsistriga** Strd. there is in the forewing but 1 subapical spot and a broad light stripe on the analis. Guiana, Colombia, Amazonas, Peru, Mexico, Honduras. — In **lampira** Prt. only the costal-marginal spot of the discal band is distinct and rounded off; the subapical spot is yellow. South Brazil, Paraguay, Uruguay, a similarly coloured specimen also from Honduras. — **fucata** Prt. is on the hindwing above and on both wings beneath orange instead of yellow; Rio Uruguaya, Brazil.

Ph. solilucis Bth. (68 a). Yellow, in the forewing the costa as far as the centre, the hind-margin, and a transverse band as well as the apical part are black, the latter with a yellow subapical spot. Hindwing yellow, distal margin and apex black. — In **subintrusa** Warr. the black discal band extends into the following yellow transverse band; — in **perintrusa** Prt. the latter is divided into two yellow spots, in **contingens** Warr. (= *aurata* Warr.) the posterior margin of the forewing is yellow, otherwise like *solilucis*. Panama, Brazil, Peru; at the latter patria *contingens* seems to predominate.

- bicolor*. **Ph. bicolor** *Mschlr.* (= *costidentata* *Dgn.*) (68 a). Hindwing as in the preceding, in the forewing the black discal band is absent, the broad black costa projects in its place only with a tooth. Hind-margin yellow. Guiana.
- amazonica*. **Ph. amazonica** *Drc.* (= *brunnea* *Warr.*) (68 b). Forewing blackish-brown, with a pale yellow triangular basal spot and a similar large subapical spot, hindwing deeper yellow, costa and distal margin bordered with black. Amazonas, Venezuela.
- hazara*. **Ph. hazara** *Btlr.* (68 b) varies in the marking and colouring, being red-brown and yellow in the forewing, the distal margin and hind-margin and a narrow part of the costa being black, as well as broad streaks on the analis and radius in the cells 2 and 3, and an anteriorly open horse-shoe at the end of the discoidal cell. Hindwing blackish-brown with a more or less extended light longitudinal stripe behind the discal cell. —
- heliconides*. The form **heliconides** *Prt.* has an entirely black apical area without a light subapical band. Brazil, Peru. The model of the species is *Stalachtis calliope* *L.* (vol. V, pl. 143 b); it otherwise makes entirely the impression of a *Pericopsis* (*Chetone*) and has originally also been described as such.
- integra*. **Ph. integra** *Fldr.* (68 a). Red-brown, distal margin on both wings broad, costa of forewing narrowly black. Costa of hindwing and a discal band of forewing pale yellow, fringes at the apex of forewing white. Brazil.

2. Genus: **Myonia** *Wkr.*

Distinguished from the preceding genus by the 1st cubital vein in the hindwing rising with the 3rd median from the same place or forked; if this is not the case, at least the antennae of the ♂ are only ciliated.

1. Hindwing chiefly yellow or white, wings nowhere hyaline (*Dialephtis* *Fldr.*).

- salvini*. **M. salvini** *Fldr.* (68 b). Yellow, with blackish-brown margins of the wings (except the hind-margin of the hindwing). Subcosta of forewing yellow. Guatemala; Colombia.
- semimarginata*. **M. semimarginata** *Dgn.* Like *salvini*, but the hind-margin of the forewing is not black, the black distal-marginal band of the hindwing is broader. Colombia.
- bicurvala*. **M. bicurvata** *Bastelb.* (68 b) is like *salvini*, the costal margin of the forewing is straighter, the black distal margins of both wings broader, that of the forewing extending to the cell. Peru, Colombia.
- josia*. **M. josia** *Fldr.* (68 b). Forewing blackish-brown, with a yellow large basal spot behind the cell, and a yellow transverse band not reaching to the hind-margin. Hindwing yellow, distal margin and hind-margin black as well as a basal stripe in the cell and one behind it. Costal margin yellow. Brazil.
- macropoecila*. **M. macropoecila** *sp. n.* (68 c). Size and hindwing as in *josia*, but the hind-margin narrower black. In the forewing the yellow basal triangle fills up a large part of the cell, the discal spot is very broad (5 mm). Peru. ♀-type from the Chanchamayo in the Berlin Museum.
- pyraloides*. **M. pyraloides** *Wkr.* (68 c) is like *josia*, mostly larger, in the hindwing the hind-margin is broader and the costal margin coherently black, only the extreme costa yellow as far as the subcostal cell. — In the form
- tongioplaga*. **longioplaga** *Warr.* the postdiscal band of the forewing is not broad at the costal margin either, but rounded off. Colombia, Brazil.
- dominula*. **M. dominula** *Warr.* resembles the preceding. The hind-margin of the forewing finely yellow, in the hindwing the hind-margin and fringes are yellow; in the anal part a stripe of black scales. The yellow centre is beneath twice as broad as above. — Expanse of wings: 35 mm. Argentina, Uruguay.
- alea*. **M. alea** *Drc.* Forewing pale yellow; apex, distal margin and hind-margin broad black, a black costal streak from the base to about $\frac{1}{2}$ of the wing. Hindwing yellow, with a black marginal band at the costal margin, apex and distal margin as far as the tornus. Expanse 31 mm. Ecuador.
- priverna*. **M. priverna** *Cr.* (♂ = *privigna* *Hbn.*) (68 b). Forewing brown, veins at the base (particularly in Brazilian specimens) paler, a whitish-yellow postdiscal band from the costa to the 2nd cubital vein; in the ♂ it is mostly straighter and more robust, in the ♀ thinner, more bent, posteriorly very narrow. Hindwing yellow with a black distal margin, in the ♀ often also a stripe below the costal margin and sometimes even the hind-margin blackish. Beneath in the forewing a yellow spot at the hind-margin, which may reach in front to the radius and distally to $\frac{4}{5}$ of the analis. — In the form **fulva** *Warr.* the blackish-brown markings are stated to be merely brown on both wings, in the forewing the whitish band above only extends to vein 5, beneath to 3, it puts forth a pointed tooth proximally at the cross-vein. Guiana, Brazil.
- quadriguttata*. **M. quadriguttata** *sp. n.* (68 b) has a habitus similar to the *Polypoetes*. Forewing black, veins red-brown, a large yellow spot distally to the transverse vein, some yellowish dusting behind the cell. Beneath the yellow spot is broader, almost reaching the costal margin, a yellow hindmarginal spot behind the centre of the cell. Hindwing black with a yellow discal spot which is continued to the hind-margin in yellow dusting, beneath yellow, distal margin and basal spot in the cell black. Peru. ♂ type from Moxos in the Berlin Museum.
- quadricolor*. **M. quadricolor** *Wkr.* (68 c). Forewing brown, with light vein-streaks at the base and a club-shaped light basal stripe on the axillaris, a light postdiscal transverse band which is posteriorly shortened and yellow at the costal margin. Hindwing yellow, edged with black. Expanse 27 mm. Amazons.

M. regis *sp. n.* (68 c). Body yellowish-brown, in some places blackish, particularly two abdominal *regis*. lateral stripes which are posteriorly fused on the dorsum, under surface whitish-yellow. Basal half of forewing lighter yellow, apical half and costal margin and hind-margin narrowly black. Costa, subcosta, and anterior edge of the cell along the same spot yellow. In the apical half a more orange-yellow spot, the hindwing darker yellow, apex and distal margin black, the latter angular at the 2nd median. Behind the cell a black basal spot. Sometimes the yellow colour is uniform in all the spots. Peru, Rio Pachitea, and Puerto San Matro (♂-type) in the Berlin Museum.

M. celata *Warr.* resembles *priverna* (68 b), the discal band in the forewing is merely a small spot situate *celata*. farther proximad. All the veins in the forewing pale, beneath the yellow colouring more extensive; only the apex, distal margin and hind-margin, and a wedge-shaped costal spot filling up also $\frac{3}{4}$ of the cell remain black. The expansion of the yellow discal spot also shows through above. Hindwing yellow, apex and distal margin black, the base also a little dusted with black. — Whilst in the normal form the costal spot of the forewing above is small, occupying only the space between the veins 10 and 11, it is larger and broader in f. **unimacula** *Warr.* and may extend to the posterior end of the cross-vein. Peru, Bolivia, Upper Amazons. *unimacula*.

M. biplagiata *Warr.* Forewing brown, veins yellow, with 2 orange-yellow spots, one beyond the cross- *biplagiata*. vein below the costal margin extending to vein 4, the second behind the cell, extending beyond vein 2 and posteriorly to the axillaris. Hindwing orange-yellow, with a narrow black border, at the costal margin and distal margin as far as the tornus. Forewing beneath with the yellow spot extended behind the cell to the base. Expanse 38 mm. Bolivia. — In **peruviana** *Dgn.* (68 c) the contours of the basal spot extend from the base along *peruviana*. the cubitus to the origin of vein 3, from there across the vein 2 and the fold as far as about 2 mm above the hindmargin, thus filling up the greatest part of the anal area. Peru. Expanse of the ♂: 32 to 34 mm.

M. graba *Drc.* (68 c) is similar to *biplagiata*, the yellow spot behind the cell in the forewing beneath *graba*. not extended to the base, above sometimes reaching to the hind-margin. Hindwing with a broad black border (width $\frac{1}{3}$ of the wing), base black, sometimes beneath connected with the marginal band. Peru, Upper Amazons, Ecuador. — In the form **primula** *Dgn.* the spot behind the cell is prolonged to the hind-margin. *primula*.

M. papula *Dgn.* Forewing chestnut-brown, costal margin as far as $\frac{2}{3}$ finely yellow, veins paler; a *papula*. yellow flattened spot in the posterior centre of the cell, another one distally to the cross-vein, being larger in the female, whilst the first disappears. Hindwing yellow with a distal margin of about $2\frac{1}{2}$ mm, but narrower on the 2nd median. In the ♀ on the hind-margin, analis and in the cell a short black basal ray, in the ♂ only traces of it. Forewing beneath blacker, spots more yellow, the postdiscal spot enlarged, with a large yellow basal spot. Hindwing without basal streaks beneath. Expanse 35 mm. Amazons.

M. ederi *Prt.* approximates *graba* (68 c), the yellow markings are lighter and more extensive, the distal *ederi*. margin of the forewing is less slanting. The spot below the cell in the forewing begins near the base and extends much farther towards the margin, so that it is almost fused with that behind the cell, being only separated from it by a dark line along the 3rd median. The black margin of the hindwing of an average width of 3 mm, as in *graba*. Expanse ♂ 37 mm. South East Colombia.

M. projecta *Warr.* resembles *ederi*, the markings in the forewing are whitish-yellow, in the hindwing *projecta*. darker yellow. Expanse: ♀ 44 mm. Rio Madeira.

M. augusta *Warr.* Forewing blackish-brown, with a golden yellow discal band being broadest in the *augusta*. centre, posteriorly narrowed, and terminating at about $\frac{2}{3}$ of the analis. Veins lighter, except near the discal band. Hindwing golden yellow, with a broad black distal-marginal band, the broadest at the apex and tornus. Beneath the costal margin of the forewing is yellow as far as the centre, fringes at the apex white; in the hindwing at the apex a yellow spot in the black distal margin, a basal black streak below the costal margin, the abdomen above with a yellow dorsal line. Expanse 35 mm. Rio Madeira.

M. cuneiplaga *Prt.* differs from *augusta* in the abdominal dorsal line being broken up into spots, the *cuneiplaga*. distal band of the forewing being more slanting, directed towards the tornus, almost equally wide; hindwing above only with a reduced, streak-shaped central area, the greatest width of which is $2\frac{1}{2}$ mm, beneath broader yellow, no yellow spot at the apex, fringes quite uni-coloured. Surinam.

M. prouti *sp. n.* (68 d) is similar to the two preceding, the dorsal line of the abdomen broken up into *prouti*. spots, forewing as in *augusta*, but the costal margin beneath not yellow, hindwing similar to *augusta*, but without the yellow apical spot, costal margin black, the broadest at the base, connected with the black distal margin, fringes at the apex of the forewing white. Body blackish-brown, the 1st and 2nd palpal joints, sides of thorax in front, inner edge of patagia, and lateral stripes of abdomen yellow, abdomen beneath whitish. Expanse 36 mm. ♀ type from Bahia in the Berlin Museum.

M. cingulina *Drc.* Forewing blackish-brown, veins reddish-yellow, behind the cell a whitish-yellow *cingulina*. spot, the centre of which is situate proximally to the origin of the 2nd cubitus; distally to the cross-vein an equally coloured smaller spot. Beneath the veins are not yellow, the proximal spot as above, not extending on the median to the base, the distal spot being much larger. Hindwing lighter whitish-yellow, the margin 3 to 4 mm broad black, the anal margin, base, and costal margin basally narrow black. Beneath the

light markings are more extensive, costa and base yellow, only a basal streak on the anterior edge of the cell is black; — in *semimaculata* Warr. (68 c) the distal spot is absent. Peru. — In *cingulina aurantica* Drc. (68 c) also the proximal spot of the forewing is entirely absent, whereas on the under surface it is distinct, extending at the posterior edge of the cell to the base. — Whilst the typical form also lacks the distal spot, the transitory form *spumata* Warr. exhibits behind the cross-vein and on the analis some small heaps of white scales; — in *albifrons* Warr. there is a distinct whitish-yellow spot at the cross-vein. Bolivia, one specimen also from Callanga (Peru).

steno-ran-
tha. **M. stenoxantha** sp. n. (68 d) differs from all the forms of *cingulina* in the base and costal margin of the hindwing being broader black, whereby the yellow transverse band becomes much narrower (3 mm broad); its edges are parallel, not divergent as in the preceding. In the forewing the proximal yellow spot is smaller than in *semimaculata* (68 c), more distally placed; its centre is situate below the origin of the 2nd cubitus. The distal spot is very large, sharply defined, larger than the proximal spot; under surface as in *semimaculata*. Huayabamba, Peru. ♂ type in the Berlin Museum.

inaria. **M. inaria** Drc. (= *maria* Dgn.) entirely resembles *cingulina*, but the proximal spot of the forewing above is extended to the base. Ecuador.

mimica. **M. mimica** sp. n. (68 d) entirely corresponds with *Josia oribia* (71 b), but the abdomen is black, with a yellow dorsal line and yellow lateral lines, beneath whitish. GARLEPP captured the only ♀ with a series of *J. oribia* on the Rio Songo, Bolivia. Type in the Berlin Museum.

tapajoza. **M. tapajoza** Dgn. Forewing brownish-black, with paler veins, an oblong, slanting median spot is yellowish, not reaching the costal margin, its distal edge crossing the cell and the 2nd cubitus before its centre, being rounded off above the axillaris; the inner margin touches the posterior margin of the cell at the rise of the 2nd cubitus and extends from there straight to the costal margin; largest width of the spot $2\frac{1}{2}$ mm. Hindwing black with a yellow transverse band from before the centre of the costal margin to that of the hindmargin, the outer side of which does not cross the transverse vein; its largest width is $3\frac{1}{2}$ mm; beneath it is extended to the base, and at the costal margin it extends to the apex, which is beneath with a round yellowish-white spot. Expanse 28 mm. Amazons.

2. Wings more thinly scaled, mostly with hyaline areas. (*Erbessa* Wkr., *Phelloe* Wkr., *Pseuderbessa* Btlr.).

citrina. **M. citrina** Drc. (= *conjuncta* Dgn.) (68 d). Wings blackish-brown; reddish-yellow are on the forewing the costal margin almost to $\frac{1}{2}$, a broad discal band, a longitudinal streak on the analis, in the hindwing the central area as far as the hind-margin, and an apical spot. A subapical band and some submarginal spots below it dull whitish. Amazons.

ovia. **M. ovia** Drc. is like the preceding, but all the markings are dull whitish. It may be only a form of *citrina*. Amazons.

capena. **M. capena** Drc. (68 d) is like the preceding, but all the markings are whitish, the discal bands hyaline. It is not the ♂ of the preceding, as had been presumed; in the Berlin Museum there are also ♀♀ of the species. Amazons, Ecuador, South East Peru.

pales. **M. pales** Drc. (68 d) is black, with a hyaline basal spot, shortened discal band and subapical band in the forewing, a similar central area as far as the hind-margin in the hindwing, at the base behind the analis in the forewing with a blue reflection. Ecuador, Bolivia.

glaucaspis. **M. glaucaspis** Wkr. (68 e) is black, the base of the forewing, and the hindwing with a blue lustre, the veins of the forewing basally whitish, in the disc a large hyaline spot, in the hindwing a whitish hyaline central spot which is sometimes darkened by grey and very narrow. Fringes at the apex of the forewing and a spot at the apex of the hindwing beneath white. Amazons, Colombia.

umbrifera. **M. umbrifera** Wkr. (= *decorata* Wkr., *munda* Wkr.) (68 e). Blackish-brown, base of forewing and greatest part of hindwing suffused with blue, an oblong discal spot in the forewing and a central spot of the hindwing hyaline, the latter of different extension, sometimes ending before the base. Beneath the apex of the forewing white as above, hindwing with a broader white apex only beneath. Amazons, Guiana. — **cassandra** Drc. is somewhat larger, with more glaring colours. Colombia, Bolivia, Ecuador.

sobria. **M. sobria** Wkr. (68 e). Abdomen with a lighter dorsal line, base of forewing with whitish veins, but not lustrous blue, a whitish-hyaline discal spot in the forewing, a similar central spot in the hindwing, fringes at the apex of the forewing only beneath, a spot at the apex of the hindwing likewise beneath, white. The black areas of the hindwing above of a blue iridescence. Brazil, Ecuador.

corvica. **M. corvica** Dgn. Like *sobria* (68 e), but the hindwing above without any blue lustre, beneath without a white apical spot. Expanse 34 mm. Bolivia.

M. semiplaga Warr. is distinguished from the 3 preceding species by the absence of the white apical spot on the hindwing beneath. The central area of the hindwing terminates behind on the median. Colombia. — In **pleni-plaga** Prt. the hyaline central area is extended yet behind the median in the hindwing. Bolivia.

M. avara Drc. Like *sobria* (68 e) with a white abdominal line and white apex of the hindwing beneath, instead of the discal spot there is a discal band in the forewing, which, however, does not reach to the costal margin. Expanse 38 mm. Ecuador.

M. conigera Prt. Hindwing beneath without a white apex, forewing with a white discal band as in *avara* on the hind-margin, but more proximally, shorter, being broadest behind, not traversing the cell. East Peru.

3. Wings with a dark ground-colour, without hyaline areas (*Myonia*).

M. lindigii Fldr. (68 e). Patagia uni-coloured. Wings blackish-brown, forewing with an orange discal band, hindwing with an intense blue lustre, with an orange costal spot before the apex. Panama, Colombia.

M. leechi Prt. Patagia with a yellow stripe. Smaller and with narrower wings than *lindigii*, the yellow band of the forewing much broader, not reaching to the axillaris. Hindwing without a yellow apical spot, the blue lustre only present in the anal part. Amazons.

M. decolorata sp. n. (68 f) approximates *lindigii*, but the hindwing is without any blue lustre, the yellow markings are of a deeper orange-yellow, the discal band of the forewing is broader, at the costal margin widened, the apical spot of the hindwing larger, otherwise entirely corresponding with *lindigii*, also in its size. Brazil, Leopoldina. ♀-type in the Berlin Museum. (In the habitus the species looks like very large *Brachyglene caenea* Drury.) To this species probably belongs another ♀ from Panama, being somewhat smaller, with quite whitish markings, but otherwise corresponding with the type.

M. euryzona Prt. Forewing similar to *leechi*, basal half black, principal veins of a thicker yellow, a yellow central band of 4 to 5 mm width from the costa to close in front of the tornus, apical half black. Hindwing black, suffused with blue (except at the distal margin), a narrow whitish costal stripe which grows broader and yellow towards the apex and expands in an apical spot. Forewing beneath with a whitish basal streak in the cell, before it some orange scales, the yellow band broader. Hindwing beneath not blue, but with a distally widened white stripe behind the cell and the 3rd median, another shorter and thinner one behind it. Expanse 32 mm. Bolivia.

M. depravata sp. n. (68 f) is similar to *decolorata* (68 f), smaller, the band of the forewing yellowish-white, steeper, not broader at the costal margin, narrower at the hindmargin; apical spot of hindwing likewise whitish, smaller; half of 3rd palpal joint yellow, and a yellow stripe on the patagia. Abdomen blackish-brown, with a yellow lateral line, beneath narrowly dirty white, at the end yellow. Length of forewing 12 (♂) and 16 (♀) mm. ♂♀-types from the Orinoco in the Berlin Museum. — Whilst in the nomenclatural race the white band is 2 mm broad at most and tapers off posteriorly, it is in the Bolivian race **amplificata** subsp. nov. 3 mm broad and posteriorly hardly narrower. ♀-type in the Berlin Museum. — In **flavifascia** subsp. nov. the light markings are yellow, the band posteriorly not narrower, the apical spot of the hindwing larger. Peru. ♀-type from Yurimaguas in the Berlin Museum.

M. saga sp. n. (68 f) resembles *depravata*, the apical spot of the hindwing is absent, replaced by a narrow costal-marginal streak. Palpi black, frons, stripe on the patagia and a dorsal line across the thorax and abdomen whitish, abdomen beneath broader white. Distal margin of forewing less convex than in *depravata*. Venezuela. ♀-type from Puerto Cabello in the Berlin Museum.

M. labana Drc. (68 f). Blackish-brown, veins of forewing scarcely lighter, forewing with a uniform white transverse band, hindwing only with a narrow yellow streak at the costal margin before the apex, beneath with a large yellow apical spot. Ecuador, Brazil.

M. aequivoca Warr. (68 f) resembles *labana*, but lacks the yellow apical spot of the hindwing and the blue lustre. Expanse 39 mm. Venezuela, British Guiana.

M. ursula sp. n. (68 f). Blackish-brown, abdomen beneath and on the sides whitish, forewing with a yellow transverse band, hindwing uni-coloured, above with a slight blue reflection. Brazil. Forewing somewhat narrower than in *aequivoca*, the band of the forewing begins a little more distally and is quite straight, in *aequivoca* somewhat distally convex.

M. desmotrichoides sp. n. (68 f). In the habitus very similar to the Syntomid genus *Desmotricha* (pl. 23 c); frons white, head, collar, stripe on patagia, middle line on thorax, lateral lines and a dorsal spot at the posterior edge of the 3rd segment on the abdomen yellow, ventrum whitish. Wings long and narrow. Forewing in the basal half with pale yellow veins, in the centre with a yellow transverse band as far as the axillaris and white apical fringe. Hindwing with a narrow yellow costal-marginal stripe and a yellow oblong

postcellular spot. Hindwing beneath with more extensive yellow markings and a yellow apical spot. Length of forewing 12 mm. Amazons. ♂-type from Massauary in the Berlin Museum.

subalba. **M. subalba** *sp. n.* (68 d) is very closely allied to *M. labana* (68 f), in the hindwing beneath a large, white central spot from the centre of the cell to the hind-margin, a white basal streak on the cubitus of the forewing and on the costa of the hindwing. Amazons. ♂-type from Pebas in the Berlin Museum.

mitys. **M. mitys** *Drc.* Forewing black, veins yellowish, with a yellow transverse band beyond the centre. Hindwing black, with a yellow spot at the cell-end, beneath with a yellow apical spot. (Was not before me). Expanse 38 mm. Amazons.

seducta. **M. seducta** *Prt.* Thorax and anterior part of abdomen with a whitish dorsal stripe, forewing with a shorter discal band which does not reach the 2nd cubitus here and is of a yellowish-white colour. Hindwing beside the yellowish-white central spot with an oblong spot near the hind-margin. Hindwing beneath only black in abasal streak and the distal margin, otherwise light yellowish. Expanse: 30 mm. (♂). Venezuela.

maera. **M. maera** *Schs.* (68 g) resembles the 3 following species, larger, the transverse band of the forewing more oblique, terminating in the tornus, uniformly broad almost to the costal margin. The yellow central area of the hindwing more extensive, base scarcely black. Brazil.

evippe. **M. evippe** *Wkr.* (68 g). Blackish-brown, veins in the forewing yellowish, forewing with a yellow discal spot which does not extend posteriorly beyond the 2nd cubitus. Hindwing blackish-brown with a yellow transverse band which is narrower at the hindmargin and the distal edge of which is angular. Amazons, Ecuador. Venezuela.

evippoides. **M. evippoides** *sp. n.* (68 g) is like the preceding, the discal spot of the forewing broader, posteriorly extending to the analis, the band of the hindwing broader, hardly narrower at the hindmargin. Colombia. ♂-type in the Berlin Museum.

assimilis. **M. assimilis** *nom. nov.* (= *pyraloides* *Wkr.* 1856 nec 1854) (68 g). Forewing without yellowish veins, fringes at the apex white, discal spot in the ♂ as in *evippe*, in the ♀ extending as a band across the analis, the distal edge of which traverses the cross-vein. Wings beneath at the base with a hyaline hue, hindwing beneath without the apical spot of *evippe*. Amazons.

imitatrix. **M. imitatrix** *Warr.* is reported to resemble *assimilis* (68 g), but with uni-coloured fringes. It may belong to a different genus? Rio Madeira.

basivitta. **M. basivitta** *Prt.* (68 g) is very much like the *Pericopina* *Scearctia figulina* *Btlr.* (65 i). Blackish-brown, forewing yellow with a black costal margin, apical third, hindmargin, and basal streak on the analis. Hindwing blackish-brown. Brazil. — Not to be mistaken for the very similarly coloured *Euryptidia basivitta* *Wkr.* (36 f).

3. Genus: **Dolophrosyne** *Prt.*

In the forewing the 2nd radial rises from the cell, the 1st cubitus is forked in both wings. But one species:

mirax. **D. mirax** *Prt.* Body blackish, wings hyaline blackish grey, the veins of the forewing somewhat yellowish-brown, hindwing at the base still more thinly scaled. Expanse 24 mm. East Peru.

4. Genus: **Tolimicola** *Prt.*

In the forewing the 2nd radial is forked with the 3rd to 5th, rising before the 5th, the 3rd radial branching off beyond the 5th, the 1st cubitus not forked, nor is it in the hindwing, rising far away from the 3rd median. Forewing not hyaline.

consanguinea. **T. consanguinea** *Dgn.* (= *fassli* *Prt.*). ♀ forewing above uni-coloured dark brown, with yellow dots on the veins and a subterminal line of yellow crescents. Hindwing blackish, feebly diaphanous. Body dark brown, base of tegula with a yellow spot, abdomen beneath somewhat paler. In the ♂ traces of whitish crescents in an antemedian and a postmedian line. Subterminal crescents white instead of yellow, distally to them yellow vein-spots and then marginal spots. Hindwing beneath with yellow marginal spots. Expanse about 45 mm. Colombia.

nubilata. **T. nubilata** *Dgn.* Wings cloudy light grey, diaphanous, forewing in the anterior basal half dusted darker, the same along the costal margin. Darker is also a median and a subterminal transverse band. Hindwing uni-coloured. Colombia, at an altitude of 3800 m. in September.

5. Genus: **Cacolyces** *Warr.*

Distinguished from the preceding genus by the 1st cubitus nearing the 3rd median. But one species:

plagifera. **C. plagifera** *Wkr.* (68 h). Forewing with two yellowish-white spots, one on the centre of the costal margin, the other at the tornus, apex at the end white, otherwise the ground-colour is blackish-brown. Hindwing coloured the same, with a broad yellowish-white discal stripe which does not reach the apex. Amazons, Venezuela.

6. Genus: **Xenorma** *Prt.*

In the forewing the 2nd radial is forked, and rises before the 5th, the 3rd radial beyond the 5th. 1st cubitus separate, in the hindwing forked.

X. cytheris *Drc.* (68 h). Forewing black, at the base with 2 yellow longitudinal stripes, a light yellow *cytheris*. discal spot and a similar subapical spot. Hindwing lighter yellow, with a black distal margin, hind-margin, and base. Tegulae and palpi yellow. Expanse about 30 mm. Mexico to Panama. — In **australis** *Prt.* (68 h) *australis*. from Brazil the central spot of the forewing is reduced, whilst in the form **deleta** *Prt.* it is entirely absent; the *deleta*. latter also occurs in Venezuela.

X. ovata *Dgn.* Similar to *cytheris* *Drc.* (68 h), but the forewing above lacks the subapical spot; palpi *ovata*. and tegulae black, not yellow as in *cytheris*. Colombia.

X. pictifrons *Warr.* (68 h). Forewing similar to *cytheris*, all the veins broadly sulphur-coloured. *pictifrons*. Hindwing whitish, with a broad black distal margin which is narrowly continued at the costal margin as far as the base. Beneath the veins are very pale, a whitish stripe from the base at the costal margin and on the cubitus, increased to a large spot at the cell-end. In the hindwing the costal margin is also white. Expanse 30 mm. South East Peru.

X. grandimacula *sp. n.* (68 h) differs from *cytheris* in the forewing showing all the veins broadly *grandimacula*. yellow and in the absence of the yellow basal streaks, the discal spot being roundish as in *reducta*. Lower base with 2 hardly lighter vein-streaks, otherwise the veins are of the same colour. Hindwing yellow, distal margin broad black, base dusted with blackish. ♀ type from the Rio Songo in the Berlin Museum.

X. biorbiculata *Warr.* (68 h). Forewing similar to *pictifrons*, veins yellowish with a hyaline white *biorbiculata*. subapical spot which is crossed by 2 dark veins. Hindwing with a broad black costal margin and marginal band, the latter being half the width of the wing, base blackish; in contrast with the preceding species, the white area of the hindwing shows dark veins. Expanse: ♂ 28, ♀ 35 mm. Amazonas.

X. plataea *Drc.* (68 h). Blackish-brown forewings with a white triangular spot near the base on the *plataea*. hind-margin and an orange marginal spot between the 1st and 3rd median veins, hindwing white with a broad black distal margin and narrow hind-margin. Bolivia, Ecuador.

X. exturbata *sp. n.* Similar to *biorbiculata* (68 h), the yellow discal spot being situate farther in *exturbata*. front, half in the cell and half behind it, all the markings are pale yellow, in the hindwing the axillaris and cubitus are blackish in the yellow discal area. Expanse 32 mm. Guatemala. ♀ type in the Berlin Museum.

X. reducta *sp. n.* (68 h, i). Forewing as in *exturbata*, in the hindwing the abdominal margin is broadly *reducta*. black, so that only a yellow discal spot is left. Beneath as the preceding, below the costa a black basal streak. ♂♀ types from Bahia in the Berlin Museum. Distinguished from *cytheris* by the discal spot of the forewing being roundish and the yellow basal stripes being absent.

7. Genus: **Oricia** *Wkr.*

In the forewing the 2nd radial is forked and rises before the 5th, the 3rd beyond the 5th. 1st cubitus in the forewing separate, in the hindwing often forked. Palpi very long.

O. truncata *Wkr.* (68 i). Body ochreous, abdomen above on the last segments with 2 posteriorly *truncata*. united black stripes. Forewing light grey, with a yellow, dark grey edged wedge from the base, beneath yellow with a grey marginal band proximally edged with dark grey, being broadest at the apex and not reaching to the tornus. Mexico to Guatemala.

O. domina *Schs.* (68 i). Abdomen on the last segments dusted with black, the yellow wedge in the *domina*. ♀ bordered by the cubitus (in ♀-specimens of *truncata* lying before me it extends beyond it), but distally extending farther beyond the cell, its distal margin not straight but distally convex. Expanse 34 mm. Costa Rica.

O. homalochroa *Fldr.* (♂ = *damalis* *Schs.*) (68 i). ♀ body and wings yellow, forewing with an olive- *homalochroa*. black, broad distal margin showing light yellow veins, whilst in the hindwing the distal margin is narrower, black and indented. The ♂ is similar, but the abdomen shows a black dorsal line on the 3rd segment and black dots on the following segments, separated by white segmental bands. Wings as in the ♀, the black distal margin of the hindwing beneath also parted by light lines. Expanse 38 mm. Costa Rica, Guatemala.

O. prolifera *Wkr.* (= *bifacies* *Wkr.*, *nerias* *Fldr.*) (68 i). Forewing with a black, white-dotted basal *prolifera*. area, an orange transverse band and black apical half with 2 white spots in it, hindwing orange, apex broadly, distal margin narrowly black. Amazons.

phryganeata. **O. phryganeata** Warr. (68 h). It is doubtful whether this species and the following *venata* belong to this genus. Forewing dark olive-coloured. Veins finely whitish, a white pear-shaped spot on the analis, beyond the cross-vein a small white spot, bending inwardly towards the centre of the costa, a submarginal row of white internerval spots. Hindwing white, with a black distal margin which is broadest at the apex and narrows down towards the tornus. Costal margin narrowly black. Beneath the pear-shaped spot is roundish, which may also occur above in aberrative specimens. Expanse 36 to 42 mm. Peru.

venata. **O. venata** Btlr. Forewing blackish-brown, veins whitish, cross-vein broad white, three dentate, blackish-brown transverse lines, the first through the cell, the other beyond it, the most distal one bordered by a row of whitish, dentate submarginal spots; hindwing grey, at the apex more brown, with a blackish marginal line. Body smoky brown, abdomen grey; forewing beneath greyish-brown, costal margin whitish. Expanse 23 to 30 mm. Brazil: Espiritu Santo.

8. Genus: **Cleptophasia** Prt.

In the veins similar to the preceding genus. The 1st cubitus separate or on a short fork. Palpi moderately long.

scissa. **C. scissa** Warr. (68 i). Forewing olive-brown, with yellowish veins, a triangular yellow spot at the costa extends to the analis. Hindwing yellow, apex and hind-margin broad, distal margin between the 2nd cubitus and 3rd median narrowly black, the outermost hind-margin and fringes on it above narrowly, beneath broader yellow. On the forewing beneath the yellow spot, which tapers off posteriorly above, is almost uniformly broad yellow. Amazons.

9. Genus: **Scoturopsis** gen. nov.

Antennae of ♂ with ciliary tufts. In the forewing the 2nd radial rises with the 3rd to 5th from the same place or on a fork, the 3rd radial rising before the 5th, the 4th sometimes fused with the 5th, the 1st median very far remote from the radial fork, the cross-vein not angular at the 2nd median, the 3rd median and 1st cubitus forked. The cell is in both wings longer than half the wing, distally angular at the 2nd median; in the hindwing the radial ramus and 1st median, and the 3rd median and 1st cubitus are forked. In *Xenomigia* the ♂ antennae are combed, the 1st median of the forewing rises close at the radial ramus. Type of the genus: *Sc. basilinea*.

1. Fifth radial present.

basilinea. **Sc. basilinea** sp. n. (68 k). Forewing brown, veins hardly lighter; costal margin as far as the cell darkened by blackish, a yellowish wood-coloured line from the base on the analis to below the rise of the 2nd cubitus. Hindwing brownish black. Beneath all the wings are blackish-brown, a light spot behind the cross-vein, on the hindwing very indistinct. ♂ type from the Rio Tanampaya (Bolivia) in the Berlin Museum.

seitzi. **Sc. seitzi** sp. n. (68 k). 4th and 5th radial veins present in the forewing. Wings brown, forewing with a large milky-white trapezoid spot on the cross-vein, extending into the cell. ♂ type from Bolivia in the Coll. A. SEITZ.

2. Fifth radial fused.

extensa. **Sc. extensa** sp. n. Like the preceding, somewhat larger, the basal streak of the forewing broader, almost reaching anteriorly to the cell. Hindwing greyer, rather diaphanous, except at the margin. Bolivia, ♂ type from S. Antonio in the Berlin Museum.

uniformis. **Sc. uniformis** sp. n. Wings uni-coloured grey, somewhat diaphanous. Expanse 19 mm. Bolivia, ♂ type from S. Antonio in the Berlin Museum.

elongata. **Sc. elongata** sp. n. Forewing very narrow, head rather hairy, wings diaphanous grey, forewing somewhat darker. Peru, 2 ♂♂ from Vilcanota in the Berlin Museum.

10. Genus: **Xenomigia** Warr.

Distinguished from all the preceding genera by the 3rd radial of the forewing rising before the 5th, the cell being normal, the 1st cubitus separate or forked, the wings densely scaled. The genus occurs in several species only in Colombia, one species also in Bolivia.

veninotata. **X. veninotata** Warr. Forewing olive-ochreous, veins paler, markings blackish. Base of cubital branches and 3rd median thickly yellowish-white; a clouded black spot at the base of the costal margin, a short, bent, sometimes dentate stripe at $\frac{2}{5}$, a slanting spot in the centre of the cell, a similar one on the hind-margin at $\frac{2}{3}$, followed by a yellowish-white dot. A blackish dentate stripe extends from $\frac{1}{3}$ of the costal margin, below the centre inwardly bent, touching the pale bases of the cubital branches and terminating in a large clouded spot

on $\frac{1}{2}$ of the hind-margin. A submarginal black dentate shadow, distal to it an irregular yellowish-white band, basally projecting above the 2nd cubital and 3rd median and interrupting the black shadow, distally bordered by another black shadow which is parted by the veins. Hindwing olive-grey, somewhat diaphanous towards the base. Expanse 37 mm. Colombia.

X. concinna Dgn. Forewing brownish-black, veins yellow, the following spots white: a basal one at the base behind the cell, two paler ones in the cell, two behind the cell, between the rise of the 2nd cubitus, analis and axillaris, a postdiscal one divided by the veins, a postmedian line of white internerval spots, the apices of which show distally, and a subterminal similar line, the apices showing proximally; of the latter line the spots between the analis and 3rd median are situate farther proximally. Marginal line white and yellow. Hindwing diaphanous white, apex and fringes pale grey. Expanse 34 mm. Colombia.

X. villiopsis sp. n. In the habitus similar to *Polypoetes villia* Drc. (69 d), but in the forewing the 3rd radial rises far before the 5th, the 1st cubitus is forked. Forewing blackish olive-brown, veins loamy-yellow, the following spots are whitish: one at the base of the cell, a double spot behind it, before the rise of the 2nd cubitus, divided by the analis, a distally open crescent distally to the cross-vein, some crescents the apices of which show towards the base, before the margin between the veins 1 a to 7. Forewing beneath uni-coloured, only the crossvein-spot white. Hindwing hyaline white, costal margin narrowly, distal margin and hind-margin broadly pale black, at the hind-margin almost as far as the cell. Expanse 30 mm. Colombia. ♂ type from the Cauca Valley in the Berlin Museum.

X. sordida Dgn. Forewing greyish-brown, a broad median band and the distal margin darker, veins yellowish, the spots are white. One near the base above the analis, two small ones in the centre above and below the analis, a narrow one distally to the cross-vein, some subterminal dots between the veins 1 to 5. Hindwing pale greyish hyaline, a median shadow and the margins somewhat darker. Fringes brown, intermixed with lighter vein-dots, particularly beneath. Forewing beneath without markings, but the markings above diaphanous. Expanse 35 mm. Colombia, Tolima.

X. pallinervis Fldr. Forewing olive-coloured grey, the veins lighter. A white basal spot behind the cell, two white spots between the rise of the 2nd cubitus, analis and axillaris, a similar one behind the cross-vein, a submarginal row of white internerval spots the apices of which show proximally. Hindwing greyish-hyaline, apex and distal margin broadly blackish. Expanse about 38 mm. Colombia.

X. villiodes Prt. Similar to *pallinervis*, but the white markings are different. An indistinct pale spot near the base of the cell, a slanting whitish streak from the centre of the axillaris to the cubitus far before the rise of the 2nd cubital branch, a white spot beyond the cross-vein, and the white submarginal line of crescents. Hindwing dingy white as far as the cross-vein, sometimes also beyond it, all the margins black, the costal margin narrow, the distal margin proximad dentately projecting. Expanse 41 to 45 mm. Colombia. Distinguished from *X. villiopsis* by the spot at the base of the cell being indistinct here, the spot above and below the analis being slanting, beginning far before the rise of the 2nd cubitus (in *villiopsis* directly before it), the white area of the hindwing not or hardly extending beyond the cell, in *villiopsis* far beyond it.

11. Genus: **Pseudoricia** Prt.

In the forewing likewise the 3rd radial rising before the 5th; the cell is remarkably short.

Ps. sibyllae Drc. Forewing yellow, costal margin narrowly, distal margin very broadly black, being broadest at the costa and ending narrowly at the tornus. Hindwing yellow, distal margin black. All the veins blackish. Expanse of wings: 28 mm. Ecuador.

12. Genus: **Zunacetha** Wkr.

Forewing: 2nd radial forked, rising before the 5th and 3rd and 4th, discoidal cell shorter than half the wing. The 1st cubitus rises with the 3rd median from the same place or on a short fork; wings narrow. palpi rather long.

Z. bugabensis Drc. (68 i). Forewing white, the marginal half with black vein-streaks, basally to them two black transverse lines on the hind-margin, converging a great deal towards the costal margin, but not touching it. Hindwing diaphanous white, costal margin and distal margin broadly, hind-margin narrowly black. Panama, Colombia. — In the Peruvian race **albibasis** Wam. the whole distal part of the forewing is ash-grey instead of white, so that the dark veins are hardly conspicuous, the apex being almost olive-coloured.

Z. annulata Guér. (= *bipartita* Wkr., *nervosa* Fldr.) (68 k). Forewing as in *bugabensis*, but the distal one of the two black transverse lines extends to the costal margin, the proximal one is prolonged and reverted towards the base, so that a large ring is formed, which may be open on the hind-margin. Costal margin as far as the 2nd transverse line and a spot at the cell-end ochreous. Hindwing white, only the apex and distal margin greyish, often all white. From Mexico to Colombia, Venezuela, and Guiana.

13. Genus: **Scotura** Wkr. (*Cymopsis* Fldr.).

In the forewing the 2nd radial is forked, in running order the 2nd, 5th, 3rd, and 5th radials; the 1st cubitus is at least in the ♂ forked, the discoidal cell $\frac{1}{2}$ of the wing at most, the 2nd median nearer to the 1st or midway between the 1st and 3rd, antennae of ♂ combed. Palpi short.

- transversa*. **Sc. transversa** Warr. (68 k). Blackish-brown forewings with partly lighter veins and a broad yellow transverse band which continues also on the blackish-brown hindwing in a yellow costal-marginal spot before the apex. Beneath the markings are broader and lighter. Guiana.
- contracta*. **Sc. contracta** Dgn. is like *transversa*, but the hindwing is black, only beneath with yellow traces at the cross-vein and in the cell. Expanse 26 mm. Upper Amazon River.
- auriceps*. **Sc. auriceps** Btlr. (68 k). Forewing brown, with lighter veins, a white transverse band, hindwing black with a slight greyish-blue tinge. Head as in *contracta* yellow. Amazons.
- longipalpata*. **Sc. longipalpata** Dgn. Palpi 3 times as long as the head. Forewing black, veins lighter, with a yellow transverse band which ends already on the analis. Hindwing black, in the hindmarginal half with a blue lustre, four fifths of costal margin white. Beneath the band of the forewing traverses the analis, hindwing with a white costal margin and abdominal half. 30 mm. Amazons.
- atelozona*. **Sc. atelozona** Prt. (68 l) is similar to *auriceps* (68 h). The white band of the forewing is narrower, on both sides pointed, reaching neither the costal margin nor the analis. Hindwing with a white central spot. Upper Amazon River.
- ovisigna*. **Sc. ovisigna** Prt. is similar to *Cleptophasia scissa* Warr. (68 i), the spot on the forewing basally to the centre of the wing, oval, extending from the subcosta to the 2nd cubitus. The black margin of the hindwing is less angular at the 3rd median and extends rather straight to the 1st cubitus. Hindmargin feebly dusted with orange. Colombia.
- signata*. **Sc. signata** sp. n. Quite similar to the following, but the hindwing with a narrow whitish central area, similar to that of some races of *nervosa*, but the veins in the forewing not lighter. ♂ type from Thomar (Rio Negro) in the Berlin Museum.
- flavicapilla*. **Sc. flavicapilla** Hbn. (= *pyraloides* Wkr., *uniformis* Mschlr.). Head ochreous, wings uni-coloured brownish-grey, hindwing with a slight steel-blue tinge. Guiana, Venezuela, Amazons.
- soror*. **Sc. soror** sp. n. altogether resembles *flavicapilla*, it is somewhat more elongate, more diaphanous, the head quite uni-coloured grey. Upper Amazon River, ♀ type from S. Paulo da Olivenca (Upper Amazon).
- discolor*. **Sc. discolor** Warr. (68 l) is similar to *soror*, but the forewing with three dark dentate transverse lines. Brazil.
- nigricaput*. **Sc. nigricaput** Dgn. Like the preceding. Forewing quite pale black, hindwing the same, somewhat lighter (It may be that *soror* is merely a light form of this species). Upper Amazon River.
- venata*. **Sc. venata** Btlr. Forewing greyish-brown, veins white, hindwing white, costal margin grey, distal margin broadly blackish-brown, the hind-margin remains white; head orange. Expanse about 30 mm. Amazons.
- nervosa*. **Sc. nervosa** Schs. Forewing grey, veins whitish, hindwing diaphanous white with a black costal margin, distal margin and hind-margin showing a slight steel-blue lustre. Head ochreous. Venezuela. —
- nigrata*. In **nigrata** Warr. from Guiana in the ♂ the white area of the hindwing is covered with blackish hair, in the ♀
- intermedia*. the cross-vein is black; — **intermedia** Warr. resembles the nomenclatural race, but the white central spot of
- leucophleps*. the hindwing does not reach the base. Surinam. — In **leucophleps** Warr. (68 l) the central spot of the hindwing
- retracta*. is tapering and ends right before the distal margin. Central America. — **retracta** subsp. n., from Colombia, has a central area in the hindwing, that is quite retracted and hardly extends distally beyond the cell (♂ type
- distincta*. in the Berlin Museum). — In **distincta** subsp. n., from the Upper Amazon River, the otherwise indistinct border of the central area in the hindwing is distinctly prominent, the central area itself shorter. — In the Peruvian
- peruviana*. race **peruviana** subsp. n. (68 l) the area is distally not tapering, but uniformly broad, with a slight projection at the fork of media and cubitus. (♀ type from Huayabamba in the Berlin Museum). Peru, Bolivia.
- vestigiata*. **Sc. vestigiata** Prt. differs from the otherwise similar *nervosa* in the following marks: palpi less glaringly orange, cell of ♂ forewing shorter, followed on the upper surface by an indistinctly defined whitish spot between the median branches, on the hindwing the posterior margin is narrower black. Expanse 32 to 34 mm. Ecuador.
- longigutta*. **Sc. longigutta** Warr. (68 l). Forewing blackish-brown, veins paler grey, hindwing brownish-black, with a long guttiform white central spot enclosing the distal half of the cell; its distal edge extends from the bifurcation of veins 6 and 7 to the bifurcation of 3 and 4, the lower edge parallel to the upper one along the 2nd cubitus, at the ends rounded off. Forewing beneath with a small white spot distally to the cell, in the hindwing beneath the white spot is broader, pear-shaped, extending narrow to the base, hind-margin pale grey. Head and palpi deep orange. Expanse 30 mm. Upper Amazon River.

Sc. fulviceps *Fldr.* (= *caresa Drc.*) (68 l). Head and palpi orange, wings blackish-brown, forewing *fulviceps*. with 3 white spots, hindwing with a white central area. — In **quadripuncta** *Warr.* on the forewing the spot *quadripuncta*. distally to the cell is divided into two. Amazons, Ecuador. — In **abstracta** *Prt.* the two proximal spots of the *abstracta*. forewing are absent, only the distal one being present; in the hindwing the veins and central spot are partly black. British Guiana, also from Manaos.

Sc. distinguenda *Prt.* is larger than *fulviceps*, expanse 35 to 36 mm, and dark brown instead of black. *distinguenda*. Spots as in *fulviceps*. In the hindwing a hyaline white spot round the posterior half of the cross-vein, otherwise blackish-brown, beneath extended to the base. Upper Amazon River.

Sc. fusciceps *Warr.* Forewing black, veins paler, a whitish spot on the bifurcation of the 3rd median *fusciceps*. and 1st cubitus. Hindwing black, with a whitish central spot from the base to $\frac{3}{4}$ of the wing; posterior edge of cell, 2nd cubitus and bifurcation of 3rd median and 1st cubitus black. Beneath paler black, the light areas more extensive and with a bluish tinge. Head and thorax black (thereby distinguished from *abstracta*). — In **obstructa** *Warr.* the white spot on the forewing above is absent, the white area of the hindwing is broader, *obstructa*. occupying the whole cell. Expanse 30 mm. Upper Amazon River.

Sc. delineata *Dgn.* Palpi black with yellow base, frons and antennae black, antennae basally yellow; *delineata*. vertex black, partly yellow, body otherwise grey. Forewing whitish-grey with black transverse lines: one basally from the costal margin to the analis; a broader one before the centre, slantingly directly distally as far as the cubitus, then narrowing down again proximally to the hind-margin; a postmedian one being straight and parallel to the margin as far as the 1st cubitus, behind it very much distally bent; a broader subterminal one, connected at the apex with the blackish distal margin. Hindwing above and both wings beneath pale blackish-grey. In the ♂ these markings are more indistinct. Expanse 26 to 30 mm. Upper Amazon River.

14. Gattung: **Tithraustes** *Drc.*

Forewing: the 2nd radial forked before the 5th before the 3rd and 4th radials, the 3rd median and 1st cubitus forked, discoidal cell $\frac{1}{2}$ of the wing or a little less, femora not densely haired, antennae in the ♂ combed, wings thinly scaled.

T. chloris *Drc.* (69 a). Forewing black, a hyaline basal streak to the cell-end, beyond the centre *chloris*. of the wing two hyaline bands, neither of which reaches the margin of the wing. Hindwing whitish hyaline, apex, distal margin and hind-margin broad black, beneath the hind-margin is broad whitish-grey. Body black, abdomen beneath white. Ecuador, Bolivia.

T. subalbata *Dgn.* (69 a). Forewing black with a whitish-hyaline basal line, a transverse band of *subalbata*. 4 similar spots, in the direction of the tornus, and 3 small subapical spots which are almost parallel to the discal spots. Hindwing black, about two thirds of costal margin white, a whitish central area covered with minute black hairs, of the same colour is the hind-margin. Forewing beneath with white costal margin and veins at the base, hindwing beneath quite bluish-white; only the cross-vein black, the last third of the costal margin, the apex and distal margin as far as the analis the same. Expanse 24 mm. Bolivia. It may be only a form of the preceding.

T. salvini *Fldr.* (= *noctiluces Btlr.*) (69 a). Forewing black with two whitish basal streaks, 2 discal *salvini*. spots and 1 submarginal spot below the apex. Hindwing black with a whitish, distally expanded central area. Tegulae ochreous. Panama, Costa Rica.

T. eteocles *Drc.* Forewing dark brown, clouded with black, and on the distal margin below the apex *eteocles*. shaded with white, veins pale brown, a large round white spot at the cell-end, a small one close at the tornus, a narrow hyaline basal streak almost to the centre. Hindwing black with a broad hyaline central area. Body dark, tegulae orange. Expanse 37 mm. Guatemala, Nicaragua.

T. butes *Drc.* (= *basalis Warr.*). Forewing black with a whitish basal streak as far as the centre, *butes*. a whitish-hyaline transverse band from the costa to the tornus which it does not reach. Hindwing black with a hyaline central spot. Tegulae orange. Expanse 32 mm. Guatemala, Honduras.

T. longipennis *Schs.* (69 b). Large species with narrow wings. Forewing black with a hyaline basal *longipennis*. streak as far as before the 2nd cubitus, a similar spot distally to the cross-vein, another one before the tornus, a similar submarginal spot below the apex. Hindwing blackish-brown, a basal streak behind the cell, and a spot distally to the cross-vein hyaline. Tegulae orange. Panama, Costa Rica.

T. seminigrata *Warr.* (69 a). Forewing greyish-brown, a broad basal streak as far as the centre of *seminigrata*. the wing, a spot behind the cross-vein, and three submarginal spots whitish-hyaline, one of which is between the 1st and 2nd cubitus, the others on the 2nd and 1st medians. Hindwing whitish hyaline, costa, distal margin and hind-margin, veins and cross-vein black. Expanse 34 mm. Panama and Costa Rica.

- quinquepunctata*. **T. quinquepunctata** Warr. resembles the preceding, the basal stripe of the forewing is shorter, ending below the rise of the 2nd cubitus, the hindmost submarginal spot on the 2nd cubitus. In the hindwing the hind-margin is black, narrower than in *seminigrata*, distal margin broader black. Expanse 40 mm. Panama.
- moerens*. **T. moerens** Warr. Forewing black, basal area hyaline with black veins, a large oblong white spot behind the cell, a small one at the tornus. Two small white spots before the apex beyond the cell. Hindwing with a broad black distal margin and veins, a white spot beyond the cell, and a smaller one below it, beneath
- condensata*. with a whitish basal streak in the cell and in the anal area. — In the form **condensata** Warr. (69 a) the wing is more suffused with blackish, all the white spots are smaller. — Expanse 35 to 37 mm. Ecuador, Colombia.
- haemon*. **T. haemon** Drc. (69 a) is quite similar to *seminigrata*, browner, the submarginal spot on the 1st median is absent. Panama.
- deiphon*. **T. deiphon** Drc. (69 b). Forewing blackish-brown, base somewhat hyaline, a whitish spot behind the cross-vein, a smaller submarginal one on the 2nd median and 2nd cubitus (the latter may be absent). Hindwing hyaline white, apex broad, distal margin and hind-margin black, distal margin deeply indented at the 1st cubitus. Panama.
- esernius*. **T. esernius** Drc. Forewing dark brown, base, a round spot at the cell-end, three small streaks at the apex, and a spot at the tornus hyaline. Hindwing white, apex and distal margin black. Expanse 25 to 30 mm. Costa Rica.
- albinigra*. **T. albinigra** Warr. Forewing at the base as far as $\frac{2}{5}$ white, but veins black, particularly the analis; the distal part black with a large white cell-end-spot, a smaller white spot between the cubital branches and 2 submarginal spots below the apex. Hindwing white, distal margin and hind-margin as well as apex broad black. Expanse 26 mm. Panama.
- pyrifer*. **T. pyrifer** Dgn. Forewing black, veins lighter; at the base a white spot which is anteriorly concave, the distal part of which reaches the centre of the cell, from where it extends slantingly to the posterior margin of the cell, and then rather straight to the hind-margin a little behind the centre. Hindwing in the basal half white, the distal half being black, the white spot distally projecting at the 3rd median. Expanse 23 mm. Colombia.
- caliginosa*. **T. caliginosa** Dgn. Similar to *pyrifer*, but the white basal spot extends farther in front, in the distal end situate right below the costal margin; forewing beneath with a white subterminal spot on the 2nd median. Expanse 25 mm. Ecuador.
- inaequiplaga*. **T. inaequiplaga** Dgn. Forewing black with a postcellular oval hyaline spot and a small subterminal spot between the 2nd and 1st median. Hindwing black with a large white spot which does not reach the base, following the analis posteriorly and being more extensive on the 3rd median; the anterior edge of the spot reaches the base of the costa. Expanse 25 mm. Colombia.
- suffumosa*. **T. suffumosa** Dgn. (69 b). Forewing similar to the preceding, the spot behind the cell indistinctly defined, no subterminal spot. Hindwing black with a white central spot which is distally bordered by the cell, but it crosses it posteriorly and extends to the abdominal margin. Expanse 26 mm. Argentina.
- fulvipalpis*. **T. fulvipalpis** Dgn. Forewing black, veins dusted with yellow, except the branches from the 2nd cubitus to the 1st median, a small oblong white spot behind the cell, extending from the 2nd cubitus to the 1st median, veins beneath not yellow. Hindwing black, basal half white as far as the hind-margin. Palpi below yellow. Expanse 24 to 26 mm. Colombia.
- mirma*. **T. mirma** Drc. (= *semilugens* Warr., *dryas* Dgn.) (69 b). Forewing black, veins partly reddish-brown, basal third white, from the direction of the costal margin at the extreme base more or less blackish, the white area with a distally directed tooth at the 2nd cubitus. At the apex 2 hyaline subapical spots. Hindwing whitish, apex broadly, distal margin and tornus more narrowly bordered with black. Bolivia.
- coniades*. **T. coniades** Drc. Forewing blackish-brown with a triangular white spot on the base of the hind-margin, not reaching the costal margin. Hindwing white, only the apex broadly black. Expanse 26 mm. Ecuador.
- aliena*. **T. aliena** Dgn. (69 b). Forewing blackish-brown, veins somewhat yellowish, on the hind-margin a white spot the apex of which is in front at the subcosta, and an orange subapical spot. Hindwing white, distal margin broadly black, hind-margin dusted with blackish. Bolivia, Pern.
- latialbata*. **T. latialbata** Prt. is very similar to *erymas*, palpi whitish, not orange. Distal margin of forewing more abrupt, the veins more intensely orange, the white band broader ($3\frac{1}{2}$ to 4 mm). Hindwing at the hind-margin broader black, the irroration extending to the cell. Expanse 27 mm. Ecuador.
- nervosa*. **T. nervosa** Edw., according to the description, entirely corresponds with *latialbata*. Colour of palpi yellow, towards the tips blackish. The white spot of the forewing is broader than in *erymas*. Mexico.
- erymas*. **T. erymas** Drc. Forewing brown, veins at the base whitish, with a white discal spot, anteriorly extending to the costal margin, posteriorly to the analis and there often expanded; before the apex an orange spot. Hindwing white, apex broadly, distal margin more narrowly black. Hind-margin dusted with blackish, not extending to the analis. — In the form **albifera** Warr. (69 b) the white spot of the forewing is not parallel-margined as in the nomenclatural form, but posteriorly expanded like a club. Panama, Costa Rica. — In

undulata *subsp. n.* the white spot is at the costal margin itself broader, then somewhat narrower and likewise *undulata*, posteriorly club-shaped, the proximal border of the black border at the distal margin of the hindwing is undulate. Brazil, ♀-type from Blumenau in the Berlin Museum.

T. bialbifera *Warr.* (69 c). Forewing blackish-brown, veins yellow; a broad white band extends from *bialbifera*, the costal margin before the centre to the analis shortly before the tornus, a yellow subterminal spot on the 2nd median. In the ♂ the band is shorter and narrower, strangulated on the anterior edge of the cell, and the subterminal spot is hardly visible. Hindwing white, hind-margin broadly, distal margin more narrowly black, in the centre still more narrowed. Beneath the hind-margin is white. Expanse 30 mm. Ecuador.

T. cistrinoides *Dgn.* Forewing blackish-brown, veins yellowish; a white discal spot extends from the *cistrinoides*, costa to the tornus and terminates already before the analis; a subapical spot is likewise white. Greatest part of hindwing white, black are only the apical region as far as below the 2nd median, the distal margin from the 1st cubitus to the tornus, and the feebly irrorated hind-margin. Expanse 26 mm. Colombia.

T. creon *Drc.* Forewing brown, veins yellowish, a discal band as in *erymas*, but centrally strangu- *creon*, lated so that 2 spots are formed. Subapical spot absent. Hindwing white, apex broadly black, the black border towards the tornus entirely narrowed down. Expanse 28 mm. Costa Rica.

T. halesius *Drc.* Forewing pale brown, clouded with a darker shade, veins pale yellow, a yellow- *halesius*, ish-white spot at the cell-end, which often lacks the ♀. Hindwing white, in the ♂ the apex is white, in the ♀ the whole distal margin. Expanse 28 to 30 mm. Costa Rica.

T. crypsispila *Warr.* (69 c). Forewing blackish-brown, veins finely yellow, an indistinct pale spot *crypsispila*, distally to the cross-vein. Hindwing white with a broad black apex and distal margin, in the centre of the latter narrower. Hind-margin dusted with blackish. Expanse 33 mm. Panama.

T. cistrina *Drc.* Forewing brown, veins and a subapical spot yellow, a white transverse band from *cistrina*, about the centre of the costa; hindwing white, at the apex and distal margin broadly black. Expanse 38 mm. Ecuador.

T. cleator *Drc.* Forewing as in *cistrina*, hindwing black. Expanse 32 mm. Ecuador. *cleator*.

T. nator *Drc.* Forewing brown with yellow veins and a yellowish subapical spot; a yellowish-white *nator*, zigzag-band from the centre of the costa to the hind-margin. Hindwing brownish-white, with a broad dark brown border, the hind-margin broadly dusted with brown. Expanse 45 mm. Colombia.

T. albitumida *Dgn.* Forewing blackish-brown, veins yellow almost as far as the distal margin, a *albitumida*, transverse band beginning below the centre of the costa, proximally bordered by the cross-vein, terminating on the 2nd cubitus or right behind it; a likewise white subterminal spot on the 2nd median, two white longitudinal streaks near the base in and behind the cell. Hindwing brown with a white central triangle the apex of which is situate between the two cubital branches near the distal margin, the hind-margin being sometimes white. Veins black, distally ending in yellow dots which may also be absent. Veins beneath white, hindwing more extensively white. 34 to 38 mm. Ecuador, Colombia, Peru. A variable species.

T. augustimacula *Dgn.* Forewing brown with yellow veins, a white spot behind the cell between *augusti-* the 3rd and 1st median, a similar streak near the base above the analis. Hindwing greyish-brown, with a *macula*, white cellular spot extending to about $\frac{2}{3}$ of the wing, beneath another white spot near the base behind the cell. Expanse 44 mm. Colombia.

T. thanatos *sp. n.* (69 c). Basal half of forewing white, but the base blackish-grey, distal half blackish- *thanatos*, grey with partly sulphur-coloured veins and an orange subapical spot. Hindwing white with a black distal margin and a slightly blackish-dusted hind-margin. ♂ type from Cuzco in the Coll. SEITZ. Expanse only 22 mm.

T. demades *Drc.* Forewing pale brown, veins lighter with 3 indistinct, darker blackish transverse *demades*, bands and 3 dingy white streaks near the apex. Hindwing pale brown, somewhat hyaline at the base. Expanse 32 to 38 mm. Guatemala, Panama. — This species differs from *nigri-fascia* *Her.* in the transverse bands being blackish instead of brown, the discal band projects at the cross-vein towards the base, whilst in *nigri-fascia* it extends uniformly.

T. albilinea *Schs.* Forewing dark brown, veins brownish-yellow, with a white median stripe which is *albilinea*, bent inwards at the 2nd cubitus and angular behind the analis. Before the distal margin a greyish-brown shadow. Hindwing thinly smoky-brownish, veins finely yellow, a yellow space below the cell from the base to before the centre. Expanse 39 mm. Costa Rica.

T. maxima *Drc.* (69 c). Forewing brown, with a pale brownish transverse line across the cross-vein *maxima*, from the costal margin to the analis and a similar subterminal zigzag line. Veins light brown. Hindwing brownish-grey, turning hyaline towards the base. — The form *fumosa* *Warr.* is dark olive-coloured, a yellow spot *fumosa*, being indistinct in the nomenclatural form at the base of the cell of the forewing, the centrally situated transverse line is absent. Panama.

- nigrifascia*. **T. nigrifascia** *sp. n.* (67 k). Forewing somewhat similar to *P. villia* *Drc.* (69 d), the 1st median distantly separated from the radial fork. Forewing brown; base, a transverse band before and one behind the cross-vein dark brown like the distal margin. Veins lighter yellowish-brown. Cross-vein scarcely hyaline, 3 thin white submarginal spots between the 5th radial and 3rd median. Hindwing thinly blackish, basally somewhat lighter, hyaline. Beneath the forewing is grey, the discal spot indistinct, the submarginal spots distinctly white. Hindwing as above. Otherwise like *demades*; patria unknown. ♂♀ types in the Berlin Museum (from STAUDINGER & BANG-HAAS).
- phaëton*. **T. phaëton** *Schs.* (69 c). Forewing blackish, veins paler, 1st cubitus to the 4th radius behind the cell whitish, with a white subapical band from the 3rd median to the 4th radius, divided into spots by the veins. Hindwing black, a white basal spot in and before the cell, costal margin narrowly, distal margin more broadly, and hind-margin as far as the cell black. In the ♀ there is only a small white spot beyond the cell of the forewing. The ♂ exhibits on the forewing a stridulation-organ in the shape of a deep groove and has therefore a very short cell. Expanse 34 mm. Costa Rica.
- submaxima*. **T. submaxima** *sp. n.* (69 h). Forewing brown, clouded with blackish, veins yellowish-brown, an indistinct hyaline spot on the cross-vein, and an indistinctly defined yellowish-white subapical band between the 4th radial and 3rd median. Hindwing thinly black, a hyaline spot on both sides of the cross-vein; beneath the forewing shows a white discal and subapical spot, whilst on the hindwing the whitish-hyaline discal spot is extended to the base. Cell of forewing the length of less than half the wing. ♀ type from Chiriqui in the Berlin Museum.
- mexicana*. **T. mexicana** *sp. n.* (69 c). Cell of forewing in the ♂ very much shortened, habitus similar to that of *Pol. draudti* (69 d), but the forewing lacks the traces of the light submarginal band, the white discal spot is situate before the centre, proximally to it blackish irroration, a whitish hyaline subapical spot. Hindwing similar to *draudti*, the black distal margin is broader, the white spot extends to the 2nd cubitus and contains the cross-vein on its proximal side. In the forewing beneath the white subapical spot of the forewing is quite distinct. Mexico. ♂ type from Orizaba in the Coll. DRAUDT.

15. Genus: **Polypoetes** *Drc.*

Separated from the preceding genus by the 1st median rising nearer to the radius than the 2nd median. Wings mostly more densely scaled. As there are transitions to both genera, it would be better to combine these two genera.

- mesitana*. **P. mesitana** *Dgn.* (69 c). Forewing blackish-brown, veins finely yellow, a whitish hyaline spot behind the cell, hindwing blackish with a similar spot which, however, is proximally prolonged and partly fills up the cell, not posteriorly extending beyond it. Beneath at the costal margin and hind-margin of the forewing a bluish-white basal stripe, in the hindwing the white spot extends to the costal margin, the whole hind-margin as far as the cell and distal margin is bluish-white. Colombia.
- etearchus*. **P. etearchus** *Drc.* (= *cethegus* *Schs.*) (61 d) differs from the preceding in the discal spot of the forewing being more indistinct, the base likewise somewhat hyaline, the veins broader yellow; in the hindwing the whitish-hyaline area is posteriorly more extensive, reaching also between the two cubital branches. Forewing beneath not bluish-white, hindwing at the hind-margin as above. Mexico, Guatemala, Panama, Costa Rica.
- approximans*. **P. approximans** *Warr.* (69 d) is an intermediate species between the two preceding ones, the discal spot of the forewing is more indistinctly defined, the hind-margin of the hindwing as in the first species. Beneath the forewing is basally dusted with bluish-white. Hindwing likewise extensively bluish-white as in *mesitana*. Panama.
- satanas*. **P. satanas** *sp. n.* (69 d). Ground-colour and veins as in *mesitana*; but the light discal spot has disappeared and merely shows somewhat through from beneath. Hindwing as in *mesitana*, but the white spot posteriorly traversing the cubitus and 2nd cubitalis. Beneath all the light markings are bluish-white; base of forewing broader white, the black distal margin of the hindwing is narrower than in *mesitana*. Las Jimenez, 2400 ft. ♂ type in the Coll. BASTELBERGER in the Senckenberg Museum at Frankfurt o. M.
- tiznon*. **P. tiznon** *Dgn.* Forewing brownish-black, hindwing with a white central area in the cell. Beneath the forewing shows a bluish-white cellular spot, sometimes also a similar subapical spot, hindwing bluish-white, distal half and hind-margin blackish-brown. Expanse 26 mm. Ecuador.
- draudti*. **P. draudti** *sp. n.* (69 d). Forewing similar to *villia*, but the ground-colour more olive instead of red-brown, veins yellow, no distinct hyaline spot near the base. Hindwing black, much denser than in *villia*, also the base, a decidedly white hyaline spot having the cross-vein in its centre and not traversing the posterior edge of the cell. Beneath in the forewing the veins are only below the apex whitish-grey. Hindwing beneath as above. Size as in *etearchus*. Mexico. ♂♀ types from Misantla in the Coll. DRAUDT.
- eriphus*. **P. eriphus** *Drc.* Forewing brown, veins lighter, a hyaline spot distally to the cross-vein, a straight submarginal band from the 5th radial branch to the tornus. Wings here and there darker clouded. Hindwing greyish hyaline, costal margin, distal margin, and hind-margin broadly black, Guatemala, Panama.

P. villia Drc. (= *longipalpis* Warr.) (69 d) is said to differ from *eriphus* in a hyaline spot being situate *villia*, on the hind-margin near the base. This spot is present in the type, but neither lacks an original specimen of *eriphus* of Druce, because only the wing is damaged there. Both species are therefore probably identical.

P. nubilosa Warr. Forewing greyish-brown, veins finely yellow, a whitish spot at the base of the *nubilosa*, cell, one beyond the cell and a yellow subapical spot. Hindwing white, costal margin narrowly, distal margin broadly black. Beneath the forewing lacks the subapical spot and the yellow veins. Expanse 30 mm. Ecuador.

P. cuatropuntada Dgn. Both wings uni-coloured brown with a yellow spot right behind the cross- *cuatropun-* vein, that of the hindwing being almost twice the size of that of the forewing and of an intenser yellow. *tada*. Beneath as above, but the base is greyish-blue. Expanse 24 mm. Ecuador.

P. deldon Drc. Forewing blackish-brown, veins yellowish, a hyaline spot behind the cross-vein; hind- *delton*, wing blackish, a light spot behind the centre, nearer to the costal margin. Under surface silky white in the hindwing, only the apex brown. Expanse 25 mm. It was bred from dead leaves of the Banana plant. Guatemala.

P. semicoerulea Dgn. Forewing black with 2 white spots, one between the veins 5 and 6, the *semicoeru-* other more distally, between 5 and 4. Under surface basally somewhat lighter whitish. Hindwing black, *lea*, beneath half bluish-white, extending to the hind-margin. Expanse 25 mm. Colombia.

P. luteivena Wkr. (69 d). Forewing blackish-brown with yellow veins, behind the cross-vein an indistinct *luteivena*, greyish-hyaline spot which is beneath larger and, like the base of the wing, yellowish-white. Hindwing black with a white discal spot which does not extend posteriorly beyond the cell, beneath white with a black distal margin not reaching to the tornus and before it being slightly incised. Otherwise entirely like *approximans*, but the hindwing above is more yellowish-white; it may be only a local race. Colombia.

P. subcandidata Dgn. According to the description, the forewing above has no hyaline spot, whilst *subcandida-* the hindwing beneath shows a white round spot between the veins 4 and 6. It may be synonymous with *ta*, *luteivena* or a form of it. Colombia.

P. sublucens Dgn. (69 d). Forewing blackish-brown with yellow veins, hindwing black. Beneath the *sublucens*, forewing is whitish-blue at the base, the hindwing entirely whitish-blue except the distal margin being black as far as the 2nd cubitus, the broadest at the apex. Colombia.

P. nox Drc. (69 e). Forewing black, veins and a subapical spot yellow, hindwing greyish-black, distal *nox*, margin from the apex to the 2nd cubitus jet-black. Beneath the forewing is white at the base and cell-end, the yellow spot as above. Hindwing white, apex broadly black. Expanse 32 mm. Colombia.

P. tenebrosa Warr. (69 e). Forewing dark brown, veins finely yellow, hindwing black. Forewing beneath *tenebrosa*, blackish, base of costal margin and veins on both sides of apex whitish, base of radial branches 3 to 5 forming a spot; hindwing with whitish basal stripes, the longest at the costal margin. Expanse 24 mm. Peru.

P. leucocrypta Dgn. Forewing black with a small hyaline subapical spot, hindwing distally lighter, *leucocrypta*, otherwise also black. Beneath the forewing has a white basal streak, a white round cellular spot and a more distinct subapical spot. Hindwing white, costal margin very narrowly, distal margin very broadly black. Expanse 25 mm. Venezuela.

P. prodromus sp. n. (69 e). Forewing blackish-brown, veins finely yellow, the spot behind the cross- *prodromus*, vein as clear as glass, no subapical spot. Hindwing white, costal margin and hind-margin narrowly, distal margin broadly black, beneath the costal margin and hind-margin are also white. Expanse 22 mm. Bolivia. ♂ type from the Rio Tanampaya in the Berlin Museum.

P. rufipuncta Schs. (69 e). Forewing blackish-brown, veins, particularly basally, finely yellow, a hyaline *rufipuncta*, spot behind the cross-vein, an orange subapical spot; hindwing black, with a hyaline spot behind the cross-vein, proximally continued in a yellow irrorated area as far as the base. Beneath as above, but the forewing with a yellowish-white basal streak, hindwing yellowish-white, distal margin broadly black, at the costal margin and cubitus projecting towards the base. Brazil.

P. intersita sp. n. (69 e) entirely corresponds with *rufipuncta*, except the hindwing above being quite *intersita*, yellow, in it a hyaline spot distally to the cross-vein, the distal margin being broadly, the costal margin and hind-margin narrowly black. Colombia. ♂ type in the Berlin Museum (Nr. 7875).

P. selenia Fldr. (69 f.) Forewing blackish, at the base somewhat lighter; veins yellowish with a dark *selenia*, greyish-hyaline spot behind the cell and an orange subapical spot. Hindwing black with a whitish central area not quite reaching the base, distally extended into three tips and posteriorly extending to the hind-margin. Brazil.

P. obtusa Wkr. (69 e) is entirely like *anipleta* (69 e) and may be only a form of it. The hindwing *obtusa*, has a more uniform white central area without the distal projections, broader, more band-shaped. Brazil.

- exclusa*. **P. exclusa** *sp. n.* (69 e). Forewing blackish-brown, veins and subapical spot yellow, a spot behind the cell dark hyaline; hindwing black, at the base and hind-margin dusted with yellowish, a discal spot is yellow, behind the cross-vein hyaline. Beneath the base of the forewing is yellowish, distal margin black. Colombia. ♂ type in the Berlin Museum.
- aniplata*. **P. aniplata** *Warr.* (69 e) differs from the preceding in the spot behind the cross-vein of the forewing being more clearly transparent and larger, extending to half the distance between the cell and hind-margin. In the hindwing the hind-margin is broad black as far as the cubitus, with traces of white irroration between the veins, otherwise similar to the preceding. Hindwing beneath white, distal margin broadly black with an incision behind the 1st cubitus. Expanse 34 mm. Bolivia.
- clarata*. **P. clarata** *sp. n.* (69 f) is quite similar to *exclusa*, but the hindwing is greenish-white, behind the cell hyaline, the costal margin and distal margin broadly, the hind-margin narrowly black. ♂ type from Cucuta, Venezuela, in the Coll. BASTELBERGER (Senckenberg Museum).
- sirenia*. **P. sirenia** *sp. n.* (69 e). In the forewing the white subapical spot before the end on the 2nd median. Forewing blackish-brown, veins yellow, the whitish-yellow discal spot extends from $\frac{1}{4}$ of the 2nd cubitus almost to the costal margin and is centrally strangulated, a white subbasal spot on the axillaris. Hindwing yellowish-white, apex broadly and distal margin black, hind-margin dusted with blackish. Bolivia. ♂ type from the Rio Songo in the Berlin Museum. Distinguished from *Tithr. albitumida* by the broader black distal margin of the hindwing.
- circumfumata*. **P. circumfumata** *Warr.* (69 f) resembles *obtusa*, but in the hindwing the whole hind-margin as far as the cell is irrorated with blackish, with a white streak in the anal fold. In the forewing the spot behind the cross-vein shows dark irroration. Expanse 20 mm. Venezuela.
- fenestrata*. **P. fenestrata** *sp. n.* (69 f) is like the following, the spot behind the cross-vein is quite hyaline. Bolivia, Peru. ♂♀ types from the Rio Songo in the Berlin Museum.
- haruspex*. **P. haruspex** *Drc.* (69 f). Forewing blackish-brown with yellow veins, the basal third and a spot behind the cross-vein lighter, though not hyaline, but beneath white. Subapical spot orange. Hindwing white, apex and distal margin black. Panama.
- evanescens*. **P. evanescens** *sp. n.* (69 f) is like *haruspex*, the basal area of the forewing is more distinctly defined, beneath and above the light spot at the cross-vein is absent, the margin of the hindwing particularly at the apex is broader black. Bolivia, Peru. ♂♀ types from Coroico and Bueyes in the Berlin Museum.
- nigribasalis*. **P. nigribasalis** *sp. n.* (69 g) entirely resembles *evanescens*, but the hindwing is at the base and costal margin above black. Venezuela. ♂ type from Merida in the Berlin Museum.
- colana*. **P. colana** *Drc.* Forewing blackish-brown, veins and subapical spot yellow. Hindwing white with a black distal margin and grey hind-margin. Forewing beneath as above, but the base is white. Expanse 23 mm. East Peru.
- albiscripta*. **P. albiscripta** *Dgn.* (69 f). Wings black, veins particularly on the forewing finely white; forewing with a white spot behind the cross-vein and a similar subapical spot which is somewhat tinted yellow in the ♀. Hindwing with a white spot which is small in the ♂ and situate outside of the cell, whilst in the ♀ it extends into the cell. Beneath it occupies the whole cell and expands as far as the base and along the hind-margin to the distal margin and on $\frac{2}{3}$ of the costal margin. Expanse 26 mm. Peru.
- integra*. **P. integra** *sp. n.* differs from *albiscripta* (69 f) in the yellow and subapical spot on the forewing, whilst in the hindwing the white irroration below behind the cell only extends to the analis. Peru. ♂ type from Callanga in the Berlin Museum. Expanse 28 mm.
- picaria*. **P. picaria** *Warr.* (69 g). Wings blackish-brown, veins of forewing yellow or white, forewing with a white basal spot in and behind the cell, the latter spot extending to below the rise of the 2nd cubitus, a white discal spot and subapical spot. Hindwing dark hyaline-grey, with a black distal margin and a round white spot distally to the cell. Beneath the costa of the hindwing is narrowly white, the discal spot is prolonged to the base and expands between the cell and axillaris. Peru, Marcapata. — In **cryptophleps** *subsp. n.* the veins are only distally distinct, the white markings of the forewing are less extensive, in the hindwing the white discal spot is also above expanded towards the base which, however, it does not reach, and extends towards the hind-margin as far as the analis. Beneath also the hind-margin and the narrow stripe below the hind-margin are white, in *picaria* black. Peru, Vilcanota. 2 ♂♂ in the Berlin Museum.
- trimacula*. **P. trimacula** *Warr.* (69 g). Forewing brownish-black, veins paler, base white, in the cell hyaline, a short black basal streak on the cubitus and analis. A hyaline spot behind the cross-vein, parted by the dark veins, a white tridentate subapical spot at the radial fork. The veins on a submarginal line broader and paler. Hindwing white, distal margin broadly, costal margin and hind-margin narrowly black. Colombia.
- exclamationis*. **P. exclamationis** *sp. n.* Forewing brown, in the cell black, veins yellow. Behind the cell a white basal streak as far as the 2nd cubitus, partly extending beyond the analis, behind the cross-vein a white oval spot. Hindwing white, costal margin narrowly, distal margin broadly black; the fringe at the hind-margin is also black. Forewing beneath without yellow veins, hindwing with $\frac{2}{3}$ of the costal margin white. Bolivia. ♂ type from Mapiri in the Berlin Museum.

P. bistellata Dgn. (69 g). Forewing blackish-brown, with a white basal streak behind the cell, a *bistellata*, white discal and subapical spot. Hindwing black with a large oblong white cellular spot extending yet beyond the cell. Expanse 28 mm. Argentina.

P. vidua Warr. differs from *bistellata* (69 g) in the veins of the forewing being white or yellow, and *vidua*, the white central spot of the hindwing being much more extensive. Peru.

P. fuliginosa Dgn. (69 g). Wings diaphanous greyish-black, veins of forewing yellow. On the forewing *fuliginosa*, a white spot behind the eubitus, as long as the cell, two small spots distally to the cross-vein; hindwing with 3 similarly situate spots, and the cell partly white; hindwing beneath about two thirds white. Expanse 26 mm. Bolivia, Peru.

P. mara sp. n. (69 g) is similar to *fuliginosa*, in the forewing the veins are darker, black; only the *mara*, white spots behind the cross-vein are present. Hindwing only behind the cross-vein very indistinctly lighter. Forewing beneath as in *fuliginosa* above, hindwing with a thinly whitish-irrorated basal stripe in the cell and a similar one behind the cell as far as $\frac{4}{5}$ of the wing. Expanse 21 mm. Peru. ♂ type from Vilcanota in the Berlin Museum.

P. dynastes sp. n. (69 g). Forewing blackish-brown, veins and a large subapical spot orange, a spot *dynastes*, behind the cross-vein hyaline. Hindwing black with a yellowish-white median band which anteriorly does not extend beyond the 1st median, so that the base, costal margin and distal margin remain broad black. Hindwing beneath yellow, only the distal margin broad black, at the 2nd eubitus proximally projecting. Expanse 34 mm. ♀ type from Novo Friburgo in the Berlin Museum.

16. Genus: **Phryganidia** Pack.

Closely allied to *Polypoetes*, but the cell of the forewing longer, wings more scantily scaled. The only nearctic genus of the family. The larva of *Ph. californica*, by its habitus, resembles a Noetuid larva, it is bare and possesses an enlarged 12 th segment; the anal feet are less chitinous than the ventral feet and divergent.

Ph. californica Pack. (69 h). Wings light grey, veins darker, behind the cross-vein of the forewing, *californica*, often indistinct, three yellowish spots. California.

Ph. naxa Drc. (69 h). Wings less coarsely haired, more elongate, forewing brown, hindwing black, *naxa*, Guatemala.

17. Genus: **Stenoplastis** Fldr. (*Momonipta* Warr.).

In the habitus similar to *Polypoetes* in which, however, the ♂ antennae are distinctly combed, whereas in *Stenoplastis* each antennal joint only has a projection set with hair-pencils.

St. persimilis Dgn. Forewing pale brownish-black, in the basal half in the cell and behind it with *persimilis*, hyaline spots, a hyaline spot distally to the cross-vein, extending from the veins 3 to 11, veins for the greatest part yellowish, beneath only at the margin and at the radial fork. Hindwing white, with a broad black marginal band, but on vein 3 a white indentation, only the fringes black. Expanse 31 mm. Colombia: Tolima.

St. semisocia Dgn. resembles the following, the white area of the hindwing is smaller. Forewing black, *semisocia*, veins yellow; white are a basal cellular spot, another between the posterior edge of the cell and axillaris, an oval one distally to the cross-vein, a subterminal line, most distinctly prominent between the two cubital branches. Hindwing black, cell hyaline white, which colour extends from the cubital fork to the subcosta. Forewing beneath uni-coloured pale black, veins not yellow, no subterminal line. Expanse 25 mm. Colombia.

St. jipiro Dgn. Forewing brown with yellowish veins, a whitish-hyaline spot in the cell, at about *jipiro*, $\frac{1}{3}$ of it, another behind the cross-vein, a third on the axillaris, distally to the cellular spot, anteriorly touching the cubitus, and some submarginal crescents. Hindwing white with a broad black distal margin which is not narrower towards the tornus, but broader on the 2nd eubitus towards the base. Ecuador.

St. pellucida Dgn. (69 h) is like *jipiro*, the markings of the forewing smaller and much more contrast- *pellucida*, ing. Colombia. Very similar to *Polypoetes trimacula* Warr (69 g).

St. empheres Prt. Similar to *pellucida* (69 h), but the cellular spot of the forewing is less distinct *empheres*, and more extensive, a yellowish-white basal spot behind the cell, a yellowish subapical spot is mixed with white, the spot behind the cross-vein is smaller, the distal margin of the hindwing posteriorly narrower. Expanse 30 mm. South East Peru.

St. opaca sp. n. (69 h) corresponds with *empheres* in the black distal-marginal band of the hindwing *opaca*, being much narrower towards the tornus. In the forewing all the light spots are reduced, greyish-hyaline, scarcely distinct. The spot at the hind-margin consists here only of two minute dots before and behind the analis, the spot at the radial fork is orange like the veins, the cellular spot almost extends to the base.

The submarginal hyaline crescents between the 1st median and analis. Beneath the hyaline spots are still more indistinct, veins only in the marginal area, but on both wings yellow. Bolivia, at an altitude of 2000 m. ♂ type from San Jacinto in the Berlin Museum.

- eximia.* **St. eximia** Warr. (69 i) likewise resembles *St. jipiro*. Basal area milky white, bordered by a vertical dark spot from the costal margin to the posterior margin of the cell at about $\frac{1}{3}$, another from the latter to the hind-margin at $\frac{2}{5}$. Base from the costal margin and cell smoky grey, of the same colour a streak on each side of the analis. Before the spot behind the cross-vein on each side of the 1st radius some white scales. Hindwing with a black distal margin only from the costal margin to the 2nd cubitus, then only yet the fringes black (beneath white). In the forewing beneath the base, except the costa, is entirely white. Expanse 34 mm. Peru.
- albicuneata.* **St. albicuneata** Dgn. Forewing black, veins yellow, distally to the cross-vein a large white oval spot somewhat irrorated with blackish, being larger beneath, base beneath broadly white. Hindwing at the border black with a white large spot at the base, leaving the costal margin at $\frac{3}{4}$, and slantingly extending almost to the distal margin at the 3rd median and from there to the tornus. Hind-margin irrorated with blackish. Expanse 24 to 27 mm. Colombia.
- rubribasis.* **St. rubribasis** sp. n. (69 h). Forewing black with a yellowish-red basal spot behind the cell and a hyaline spot distally to the cross-vein. Hindwing black, cell milky white, also somewhat behind it; cross-vein black, a round spot behind it hyaline. Forewing beneath without a red basal-streak, base irrorated with whitish, hindwing milky white, distal half of costal margin, distal margin and cross-vein black. ♂♀ types from the Tanampaya, Bolivia, in the Berlin Museum; also from Callanga, Peru.
- carderi.* **St. carderi** Drc. Forewing black with a white basal streak as far as the centre and a white transverse spot behind the cross-vein. Hindwing white, distal margin as far as the tornus broad black. Expanse 32 mm. Colombia.
- flavibasis.* **St. flavibasis** sp. n. (69 i). Forewing black, veins finely yellow, a club-shaped spot at the base behind the cell and a spot distally to the cross-vein yellow. Hindwing hyaline white, distal margin broadly black, base and hind-margin irrorated with blackish. Beneath in the forewing the basal streak is white, the veins are not yellow, in the hindwing only the distal margin is black. ♂ type from Pozuzo in the Coll. A. SEITZ.
- albiplaga.* **St. albiplaga** Warr. Forewing black with 2 white basal streaks, before and behind the analis, the anterior one being broader, in front bent and at both its ends pointed, a white bent spot distally to the cross-vein. Hindwing white, distal margin broad, in the centre narrower, black; hind-margin broadly irrorated with smoky grey. Expanse 34 mm. Colombia.
- subcoerulea.* **St. subcoerulea** Warr. Forewing brownish-black, a silvery white basal streak behind the cell, distally expanded and rounded off, extending to $\frac{2}{5}$ of the forewing, a hyaline-silvery spot behind the cross-vein. Hindwing with a whitish-hyaline central area, base darkened. Costal margin narrowly, apex and distal margin as far as the 3rd median broadly black, the whole hind-margin as far as the posterior edge of the cell likewise black. The black markings of the costal margin and hind-margin are beneath bluish-white. Expanse 30 mm. Panama. — In *felderi* Prt. (69 i) the veins of the forewing are finely yellow, the white basal streak is absent; in the hindwing the white spot is often smaller. Expanse 33 to 35 mm. Colombia.
- subcaesia.* **St. subcaesia** Prt. (= *subcoerulea* Dgn.). Wings black, forewing with a white, oblong, hyaline spot behind the cross-vein, beneath at the base whitish-blue. Hindwing beneath in the basal half whitish-blue, across the whole cell as far as the tornus. Expanse 28 mm. Colombia.
- subalba.* **St. subalba** Wkr. Forewing brownish-black, veins yellow, beneath the base is white. Hindwing above brownish-black, beneath white, except the apex. Venezuela.
- satyroides.* **St. satyroides** Fldr. (69 i). Forewing brownish-black with a small greyish-hyaline spot behind the cross-vein, below at the base whitish-blue. Hindwing brownish-black, basal half for the greatest part whitish-blue, this colour projecting less distally at the cell, more distally behind it. Colombia.
- aterrima.* **St. aterrima** Dgn. Forewing jet-black, veins finely yellow, 2 small hyaline spots distally to the cross-vein between the veins 3 to 6. Hindwing jet-black, in the cell a white longitudinal stripe, traversing the cell but little, extreme base black; in the ♂ the cell is traversed only behind the cubitus, in the ♀ at the veins 2 and 7. Veins black. Forewing beneath besides with a white basal streak behind the cell. Hindwing beneath with a much expanded white stripe. Expanse 25 (♂) to 28 (♀) mm. Colombia.
- flavinigra.* **St. flavinigra** Dgn. Wings black with a very broad yellow transverse band which is broader on the forewing behind and on the hindwing neither reaches to the distal margin nor to the tornus. Forewing beneath at the base yellowish, hindwing with the yellow band as far the tornus. Expanse 21 to 23 mm. Colombia.
- unifascia.* **St. unifascia** sp. n. Uni-coloured blackish-brown, in the forewing the veins are basally finely yellow, a pale yellow, centrally strangulated, posteriorly club-shaped band extends from $\frac{1}{2}$ of the costa to the tornus, but terminates already on the fold. Beneath this band is broader, uniformly widening hindwards and bent, veins not yellow. Size as in *rubribasis*. Bolivia. ♂ type from Cillutincara (3000 m) in the Berlin Museum.

St. decorata Dgn. Forewing black with a yellow basal stripe as far as $\frac{1}{2}$ of the wing and a similar *decorata*, transverse band from the costal margin to behind the 1st cubitus. Hindwing black with an oblong yellow spot distally to the cell below the costal margin. Forewing beneath at the base bluish-white, the hindwing bluish-white in the basal half and beyond it. Expanse 25 to 29 mm. Colombia.

St. coras Drc. (= *biplaga* Dgn.). Forewing blackish-brown with a broad white basal streak behind *coras*, the cell and a white spot distally to the cross-vein. Hindwing with a white streak in the cell, distally prolonged and expanded across it, but not reaching the distal margin. A narrow and short postcellular streak. Forewing beneath with a white basal streak, otherwise as above, hindwing beneath more extensively white. Expanse 21 to 23 mm. Ecuador. — In **flaviplaga** Dgn. the white markings are yellow, those of the hindwing *flaviplaga*, larger. 20 to 22 mm. Colombia. East Ecuador.

St. aborta Dgn. Forewing pale black, the space behind the cell as far as the rise of the 2nd cubitus, *aborta*, the base of the cell, and a large spot distally to the cross-vein are whitish hyaline. Hindwing hyaline white, with a pale black distal margin, narrowing down towards the tornus, at the hind-margin some black hairs. Expanse 21 to 22 mm. Colombia.

St. grandimacula Dgn. Forewing blackish-brown, veins paler. A white spot slightly irrorated with *grandima-* grey on the outside of the cell, a pale basal streak at the cell, beneath all the markings are more distinctly *cula*, white and larger. Hindwing brown with a white central spot, beneath all white, only a pale stripe at the costal margin and a broader one at the distal margin are black. Expanse 26 to 29 mm. Bolivia.

St. euchonthoides Prt. (69 i). Forewing blackish-brown, veins yellowish, a yellowish-white spot behind the *euchonthoi-* cross-vein strewn with darker scales. Hindwing pale brown, at the base irrorated with a darker colour, margins *des*, blackish-brown, particularly broad the hind-margin. Forewing beneath similar, often yet with a light basal streak, hindwing beneath centrally whitish. The yellowish-white colouring of the hindwing is very variable, often also above very extensive. Bolivia. Peru. — In **lactigera** *subsp. n.* from the Chanchamayo all the mar- *lactigera*, kings are snow-white instead of yellowish-white and very hyaline. ♂ type in the Berlin Museum.

18. Genus: **Euchontha** Wkr.

Distinguished by the cell of the ♂ forewing occupying only $\frac{1}{4}$ of the wing.

E. clareta Dgn. (= *memor* Warr.) (69 i). Forewing brownish-black, veins paler, a broad, slanting, *clareta*, white transverse band from the costal margin to the analis before the tornus, a small white subapical spot parted by the vein. Hindwing greyish-brown, apex darker, costal margin whitish, veins paler. Expanse 30 mm. Peru.

E. commixta Warr. (= *chilion* Drc.) (69 i) is similar to the preceding, forewing at the transverse *commixta*, band only greyish hyaline, hindwing white, base grey, with broad black margins. Beneath in the forewing the median spot extends to the base. Expanse 32 mm. Peru, Bolivia.

E. ciris Drc. (= *ciris* Dgn.). Forewing black, veins black in the otherwise white basal third. A white *ciris*, double spot before the apex and a similar one above the tornus. Hindwing white, distal margin broadly black. Expanse 28 mm. Ecuador.

E. frigida Wkr. (= *sublactigera* Wkr., *albimacula* Warr.) (69 k). Forewing basally white, with blackish- *frigida*, brown veins (except the 2nd median). Apical half blackish-brown with a white subapical transverse band, hind-margin blackish-brown. Hindwing white in the central area a similar subapical spot, otherwise blackish-brown. Colombia, Ecuador. — In **longinervis** Fldr. also the 2nd median in the forewing is broadly blackish- *longinervis*, brown. Guiana, Amazons, Peru.

E. castrona Schs. is like the preceding, hindwing quite blackish-brown, beneath paler grey with dark *castrona*, veins. South East Brazil.

19. Genus: **Ceraeotricha** *gen. nov.*

Antennae of the ♀ only with cilia; in the forewing the 2nd to 5th radials are forked, the 2nd rising before the 5th before the 3rd and 4th. The 1st median nearer to the 2nd than to the radial ramus, the 1st cubitus often nearer to the 3rd median than to the 2nd, in the hindwing the radial ramus and 1st median are forked, the 3rd median and 1st cubitus separated. Posterior angle of cell far produced. Type of the genus: *G. cuneifera* Dgn.

G. cuneifera Dgn. is extremely to *Xenom. pallinervis* Fldr., but the hindwing is uni-coloured quite *cuneifera*, light brownish hyaline, in the forewing the white basal spot is absent, between the cell and axillaris a uniformly white stripe instead of two spots; ground-colour of forewing red-brown, distal margin and hind-margin wood-coloured brown, behind the cell a white slanting stripe proximally extending from the rise of the 2nd cubitus to the axillaris, behind the cross-vein a white, centrally hyaline spot, before the light distal margin a white crescentiform line. Colombia. Described by WEYMER in „Stübels Reise“ on p. 42 No 28 as *Stenoplastis pallinervis* Fldr.

20. Genus: **Phanoptis** Fldr.

In the forewing the 1st cubitus is not forked, nor in the hindwing, where it rises distantly separated from the 3rd median. Wings mostly very hyaline.

cyanomelas. **Ph. cyanomelas** Fldr. (70 d). Forewing as clear as glass, with a black costal margin, distal margin and hind-margin and 2 transverse bands and all the veins being black. Hindwing hyaline, veins, costal margin and distal margin broadly black. All the wings iridescent blue. Costa Rica, Colombia, Ecuador.

taxila. **Ph. taxila** Drc. is similar to the preceding, but with only one transverse band across the forewing. Expanse 45 mm. Colombia.

fatidica. **Ph. fatidica** Dgn. Wings black with a blue lustre, the forewing with a whitish hyaline transverse band distally to the cell from the subcosta to the 1st cubitus. Expanse 39 mm. Peru, Venezuela.

vitrina. **Ph. vitrina** Drc. (70 c). Forewing blackish-brown, with a slight blue reflection, with a hyaline, black-veined triangle at the base between the anterior edge of the cell and the axilaris as far as $\frac{4}{5}$ of the wing, and a hyaline, partly white-scaled discal transverse band and some subapical spots. Hindwing hyaline, costal margin, distal margin and veins black. Panama, Costa Rica.

millorrhabda. **Ph. millorrhabda** Prt. Wings narrower, forewing black with a brownish tinge; a slanting red band of 2 mm width extends from the centre of the costal margin to the 2nd cubitus right before the margin, the 1st radius, radial ramus and 2nd cubitus black, a bent row of 3 hyaline dots between the 5th radial and 3rd median. Hindwing black with a brown tinge. Peru: Chanchamayo. It copies *Actinote erinome* Fldr. (Vol. V. pl. 81 a) and *Eresia castilla* Fldr. (Vol. V. pl. 92 e).

21. Genus: **Authyala** Warr.

Corresponding with *Phanoptis*, but in the forewing the 1st cubitus is very near to the 3rd median.

obliquaria. **Au. obliquaria** Warr. (69 k). Wings hyaline, veins and margins blackish-brown. In the forewing the hind-margin and subcostal stripe as far as the centre are red-brown. The hind-margin is opposite the latter half of the 2nd cubitus broader. From the costa a black band, enclosing the cross-vein with which it terminates posteriorly, and another from $\frac{3}{4}$ of the costal margin to the distal margin at the 3rd median, where it is widened. Peru.

22. Genus: **Monocreagra** Fldr. (*Tanaostyla* Warr.).

In the forewing the 3rd radial branch rises before the 5th, the cell is of normal size, the wings are hyaline. Antennae ciliated, in the ♂ in tufts.

orthyades. **M. orthyades** Drc. (70 d). Wings hyaline, margins and all the veins blackish, particularly broad the cross-vein, 3rd median and 1st cubitus. Colombia, Ecuador.

pheloides. **M. pheloides** Fldr. (= *dilucida* Warr., *conjunctiva* Warr.) (70 d). Like the preceding, the hyaline space behind the cross-vein is white, the veins therein not darker. Expanse: ♀ 40 to 45 mm. Colombia, Bolivia.

unimacula. **M. unimacula** Warr. Like the preceding, perhaps the southern race of it, smaller (♀ 35 to 40 mm), apical third of forewing more extensively black, the white spot smaller. Bolivia, Peru.

disconnexa. **M. disconnexa** Dgn. Forewing whitish hyaline, costal margin narrowly black, a spot in the last third of the cell and the distal margin broadly black, in the latter 3 white spots between the veins 2 to 6, vein 5 remaining white. Hindwing whitish hyaline, apex and distal margin black. Expanse 25 mm. Colombia.

23. Genus: **Isostyla** Prt.

Radial branches as in the preceding genus, 3rd median and 1st cubitus forked. ♂ antennae with long combs.

zetila. **I. zetila** Bsd. (= *nubila* Schs.) (69 k). Greyish-hyaline wings, veins and margins darker, in the forewing a white transverse spot behind the cross-vein as far as the 1st cubitus, the 3rd median therein white, some whitish subapical spots, and in the hindwing indistinct white submarginal spots. Guatemala, Costa Rica.

erycinoides. **I. erycinoides** Fldr. (= *ithomecina* Btlr.) is similar to *zetila*, but the 3rd median in the forewing is also black. Postdiscal spot smaller, 4 submarginal spots in the forewing. Panama, Costa Rica. — **picata** Warr. (69 k) has all the hyaline places of the wings in the ♂ whitish, in the ♀ like in the ♂ and ♀ of the type *purefacta*. **I. purefacta** Prt. the cubitus and the base of its branches in the forewing are white, the hindwing is almost entirely white, with a narrow distal margin. South Ecuador.

I. intersecta Warr. is extremely similar to the preceding, but the postdiscal spot of the forewing is *intersecta*, traversed by dark veins. The dark discal band before the hyaline spot of the forewing is broad, the hyaline areas are whitish, reduced. Ecuador. — In **biquadrata** Prt. the dark discal band is narrower, in front 1, behind *biquadrata*, 3 mm broad at most, the light areas greyish-hyaline. Colombia.

24. Genus: **Paradioptis** *nom. nov.* (= Eudioptis Prt. nec Hbn. 1816).

In the forewing the 2nd radial rises before the 5th before the 3rd and 4th; the 1st cubitus is forked with the 3rd median in the forewing, whilst in the hindwing they are separate.

P. otanes Drc. (69 k). Forewing black, 2 hyaline basal streaks, a spot at the cell-end, one at the tornus *otanes*, and 2 before the apex are whitish-hyaline. Hindwing hyaline, costal margin and distal margin broadly black, like the veins; an oval cell-end spot is white. Expanse 32 mm. East Ecuador.

25. Genus: **Dioptis** Hbn.

Like the preceding, the 1st cubitus rises forked also in the hindwing.

D. candelaria Drc. (= *vacuata* Warr.). Wings hyaline, margins and veins black, in the forewing *candelaria*, a costal hook, enclosing the cross-vein, and a postdiscal band from $\frac{2}{3}$ of the costa to the rise of the 3rd median black, the area behind it whitish-hyaline without black veins; whitish are besides the space behind the cross-vein before the 1st median and two spots in the hyaline area before the tornus, as well as in the hindwing the distal areas of the hyaline area. Panama. — In **nivea** *subsp. n.* (69 k) the white subapical band is twice as *nivea*, broad (4 mm), posteriorly narrower. Colombia. ♂ type from S. Miguel in the Berlin Museum.

D. pellucida Warr. is quite similar to the preceding, but without white spots on the hyaline areas, *pellucida*. Expanse 48 mm. Colombia.

D. symoides Strd. is said to be very similar to the Pericopine *Hyalurga syma* Wkr. (65 e), but differs *symoides*, in the veins and the broader ($3\frac{1}{2}$ mm) white band of the forewing. Probably near *candelaria*. Expanse 31 mm. Costa Rica.

D. phelina Fldr. (= *pandates* Drc., *impleta* Warr.) (69 l) likewise resembles *candelaria*, but the white *phelina*, subapical spot does not reach the costal margin, extending only to the radius; at the tornus only a white spot, all the dark markings being broader; in the hindwing the space between the 3rd median and 1st cubitus is dark. Colombia.

D. areolata Wkr. (69 l). Wings hyaline, the veins and margins black, forewing with 2 broad black *areolata*, transverse bands, veins before the apex also darker. The hyaline spot before the apex is very small. Expanse 32 mm. Brazil.

D. restricta Warr. (? = *melda* Bsd.) (69 l) is similar to *areolata*, larger, 35 to 44 mm, the veins very *restricta*, fine and bands and margins narrower black, the hyaline areas more extensive. The space between the 1st cubitus and 3rd median is hyaline, in *areolata* dark. Brazil.

D. charila Drc. (69 l) is similar to the preceding, the forewing only with a transverse band, which is very *charila*, broad and oblique and touches the anterior margin of the cross-vein. Guiana, Venezuela, Columbia, Ecuador.

D. onega Bts. (69 l). Forewing hyaline, margins and veins black, two transverse bands, which are *onega*, broadly connected between the 2nd and 3rd medians. Subapical spot broad, white, veins not darker. Hindwing white, distal and costal margins black, above indistinct, beneath with a distinct ochreous line in the margin. Veins finely black. BATES found it flying together with *Leucothyris onega*, which it resembles very much. Upper Amazon River.

D. columbiana *sp. n.* is a species between *onega* and *restricta*. From *onega* it is separated on the *columbiana*, hindwing by the narrow distal margin, which is beneath not filled up with orange; from *restricta* it differs in the first transverse band of the forewing being connected with the second by dark irroration between the 2nd and 3rd medians. Expanse 32 mm. The species was captured by STÜBEL and later on denoted as *D. phelina*, but the latter has in the hindwing a dark band at the 1st cubitus, which fills up the bifurcation. Colombia. ♂♀ types from Llanos de S. Martin in the Berlin Museum.

D. pallene Drc. (70 a). Forewing blackish-brown, in the posterior half of the cell and behind it as *pallene*, far as the 2nd cubitus white hyaline, divided dark by the analis, a broad white subapical band and a white spot between the cubital branches. Hindwings hyaline, veins and margins black, distal margin with an orange line. Expanse 38 mm. Ecuador, Peru.

D. stenothyris Prt. is similar to *pallene* (70 a), in the forewing the subapical band is narrower, another *stenothyris*, white dot at the anterior end of the cross-vein, sometimes also two. Rio Madeira, Upper Amazon River.

- dentistriga*. **D. dentistriga** *sp. n.* (70 a) is similar to *stenothyris*, the veins in the subapical band of the forewing are partly black, the yellow marginal stripe of the hindwing only half as broad, distally with some projecting teeth. ♂ type from the Jurimaguas in the Berlin Museum.
- leucothyris*. **D. leucothyris** *Btlr.* is similar to the preceding, the spot behind the cross-vein about as large as that at the tornus. Subapical stripe black-veined. 35 mm. Amazons.
- tessmanni*. **D. tessmanni** *sp. n.* (70 a). The white subapical band of the forewing extends posteriorly curved to the 2nd cubitus, the 1st cubitus is not broadly black. Between the subapical band and the hyaline cellular area scarcely lighter beyond the cross-vein. Hindwing as in the preceding. East Peru, discovered by G. TESSMANN. ♂ type in the Berlin Museum. — In *opaca* *subsp. n.* (70 a) the subapical band is densely creamy-yellow, the orange band of the hindwing is more remote from the margin (1 mm). ♂ type from the Ucayali in the Berlin Museum.
- roraima*. **D. roraima** *Dre.* Forewing behind the cross-vein with a hyaline band parted dark by the veins, and a white subapical stripe, at the tornus an angular orange stripe running anteriorly and proximally. Hindwing as in the preceding. 44 mm. Guiana.
- trillii*. **D. trillii** *Btlr.* (= *fatima* *Mschlr.*) (70 b) is like the preceding, without yellow marking at the tornus of the forewing. Venezuela, Guiana, Amazons.
- angustifascia*. **D. angustifascia** *sp. n.* (70 a). Forewing as in *trillii*, subapical stripe broader, veins therein not black; in the hindwing the orange subapical stripe is only half a mm broad. ♀ type from Iquitos in the Berlin Museum.
- cyma*. **D. cyma** *Hbn.* (70 b). Forewing with 2 or 3 yellow spots below the costal margin, being the beginning of the otherwise white subapical band of which only the posterior part remains white here. Otherwise altogether similar to the preceding. Amazons. It is reported to fly together with the similar *Hypoleria cyma* (Vol. V, pl. 41 a).
- paracyma*. **D. paracyma** *Prt.* is like *cyma*, but in both the bands the veins are not black, except the 3rd median and 1st cubitus and the space between them. Rio Madeira, Surinam.
- aeliana*. **D. aeliana** *Bat.* Forewing black, a longitudinal stripe in and behind the cell, a spot behind the cell and one at the tornus and a subapical stripe are hyaline. Hindwing reddish-brown with a narrow black border and traces of a black discal band. It flies together with the similar *Ithomia aelia* (Vol. V, pl. 37g). Amazons.
- cheledonis*. **D. cheledonis** *Dre.* (70 b). The greater part of the forewing is hyaline, the costal margin and hind-margin are partly ochreous, the distal margin, a hook on the cross-vein and a transverse band behind it are black, the latter at the 1st cubitus broadly connected with the distal margin, which is filled up with ochreous before the apex. Hindwing similar to that of the preceding. Expanse 50 mm. Ecuador.
- proix*. **D. proix** *Prt.* is similar to *cheledonis*, smaller (40 to 43 mm); subapical area of forewing without, hind-margin with but scanty red-brown irroration, the yellowish stripe at the costa is absent. The space between the cross-vein and transverse band is darker, the white subapical band smaller. The spot at the tornus is smaller. Peru.
- incerta*. **D. incerta** *sp. n.* (70 a). Similar to *proix*, but smaller; the hyaline areas less extensive, only in the posterior half of the cell and behind it as far as the axillaris and between the cubital branches. The subternal spot is small, white like the 2 mm broad subapical band. Behind the cross-vein, an indistinct, hyaline post before the 3rd median. *Pallene* (70 a) has a steeper white band, other similar species are without the hyaline space between the cubital branches. Expanse 36 mm. ♂ type from the Rio Pachitea. East Peru (G. TESSMANN).
- uniguttata*. **D. uniguttata** *Warr.* (= *quirites* *Dre.*). Forewing hyaline, costal margin and hind-margin and veins black, at the apex $\frac{2}{5}$ black, containing a white band extending from $\frac{2}{3}$ of the costal margin to the 3rd median; there is a round white spot above the tornus. The anterior half of the cell and the cross-vein are black, behind the latter three hyaline dots the foremost of which is white. Hindwing as in the preceding. Expanse 40 mm. Colombia. Separated from *pallene* (70 a) by the whole space between the 3rd median and 1st cubitus of the forewing being black.
- meon*. **D. meon** *Cr.* (= *beroea* *Mschlr.*). Forewing extensively blackish-brown, hyaline are only a stripe in and behind the cell and a white transverse band behind the cross-vein, which extends from the radius to the 2nd cubitus and is angular at the 3rd median. Hindwing with a broader blackish-brown distal margin. Guiana.
- charon*. **D. charon** *Dre.* Forewing blackish-brown, in and behind the cell hyaline, the cross-vein and 2nd cubitus black, behind it a very narrow light space, then the apical third dark with a white, 3 mm broad transverse band from the costal margin to the 2nd cubitus. Hindwing with black veins and distal margin, containing a red-brown line as in the preceding species. Expanse 38 mm. Bolivia.
- indentata*. **D. indentata** *sp. n.* (70 a) differs from *charon* in the 2nd cubitus of the forewing being not broadly black, the light area behind the cross-vein is as broad as the white band which is here $1\frac{1}{2}$ mm broad at most and proximally dentately bordered at the veins, otherwise like *charon*. Expanse 28 mm. ♂ type in the Berlin Museum from the (?) Amazon River.

D. peregrina *sp. n.* (70 b). Likewise similar to *charon*, 2nd cubitus broadly black, but the subapical *peregrina*, band in the ♂ is more oblique and narrower (1 mm, in the ♀ 2 mm), posteriorly pointed. The two anterior spots behind the cross-vein in the ♂ are whitish. ♂ (type) and ♀ from Ueayali in the Berlin Museum.

D. ileridina *Bts.* (= *herdina* *Wkr.*) (70 b) is separated from the preceding by the hyaline area behind *ileridina*, the cell of the forewing being more or less irrorated with white. The subapical band extends to the cell and is broad. Hindwing similar to those of the preceding, veins for the greatest part white. Amazons. — In **curvifascia** *Prt.* from the Rio Madeira the narrower subapical band is posteriorly very much bent, in **nigrivenis** *subsp. n.* *nigrivenis*, (70 c) the veins in the hindwing are black, the forewing as in *ileridina*. ♂ type from Sarayacu in the Berlin Museum. Ecuador, Bolivia.

D. zarza *Dgn.* (= *vitrifera* *Warr.*, *albifasciata* *Drc.*) (70 c). Forewing black in and behind the cell, *zarza*, distally beyond the 2nd cubitus hyaline, with a white subapical band. Hindwing hyaline with black veins, costal margin and distal margin; without the orange stripe. Ecuador, Peru.

D. egla *Drc.* (70 c). Forewing hyaline, costal margin, hind-margin, a transverse band across the cell *egla*, and apical half blackish-brown like the veins, hyaline spots in some places also whitish. Intense ochreous irroration in the apical half and at the tornus, in the ♀ also at the costal margin and hind-margin. Hindwing hyaline, veins and margins black, distal margin with an orange stripe. — In **phaedima** *Prt.* (70 c) the veins of the hindwing *phaedima*, are white. Ecuador, Amazons.

D. climax *Prt.* differs from *egla* in the orange irroration of the forewing extending at the costal margin *climax*, to the base, being narrower before the apex and only reaching to the 3rd median, forming another spot on the tornus, which despatches projections on the axillaris and 2nd cubitus, the last of which extends to the cell. In the hindwing the black veins and distal margin as well as the orange stripe are broader. Amazons

26. Genus: **Hadesina** *Warr.*

Like *Diopsis*, but the cell in the forewing is shorter, about $\frac{1}{3}$ the length of the wing, cross-vein in the hindwing strongly angular.

H. anomala *Prt.* Forewing white, distal margin broad, hind-margin and veins narrower black. Cross- *anomala*, vein and a stripe behind the fork of the 3rd median broadly black, a slanting black band (2 to 3 mm) from beyond the centre of the costa to the distal margin between the bifurcation behind the 3rd median. A white subapical band, 3 mm broad at most, veins therein not black. Hindwing whitish, veins and margins broadly black, before the apex a white spot. Expanse 43 mm. Amazons.

H. caerulescens *Schs.* (= *chloris* *Warr.*) (70 d). Wings black, lustrous blue, particularly at the hind- *caerulescens*, margin of the forewing, and the hindwing. Veins black, above the axillaris of the forewing a bluish-white longitudinal streak. Hyaline are in the forewing a basal streak in the cell, posteriorly extending beyond it, a discal band from the radialis to the 2nd cubitus, a subapical band from the 4th radius to the 2nd median, in the hindwing an oblong central stripe from the centre of the cell to the analis, beneath in the hindwing another white stripe at the costal margin. Costa Rica.

H. limbaria *Warr.* Forewing hyaline, veins black like the margins. A small black spot at $\frac{1}{3}$ of the *limbaria*, costa, enclosing the discal dot, a broad black band from $\frac{2}{3}$ of the costa to the distal margin above the tornus. Hindwing hyaline, veins and margins black, a blackish basal stripe along the analis. Expanse 39 mm. Ecuador.

27. Genus: **Brachyglene** *H.-Schäff.*

Cell rather short, 2nd radial rising before the 5th before the 3rd and 4th. 3rd median and 1st cubitus beneath forked in *caenea*-forms.

B. caenea *Drury* (70 e). The 3rd median and 1st cubitus not distinctly forked, wings blackish-brown, *caenea*, forewing with a yellow median band, which is somewhat expanded at both its ends and continued in a spot at the costal margin of the hindwing. — In **extensa** *Wkr.* there is in the hindwing besides another yellow discal *extensa*, spot, in **fracta** *Prt.* the band of the forewing is posteriorly narrower and terminates right behind the 2nd cubitus, *fracta*, *dilatata*, — In **dilatata** *form nov.* (70 d) the band of the forewing is like in *fracta*, the hindwing is yellow except the distal margin which is narrow at the apex and broad at the tornus. (♂ type from Valencia in the Berlin Museum). — From Mexico to Brazil and Venezuela.

B. schausi *Prt.* (70 e). Smaller than the preceding, the 3rd median distinctly forked, in the forewing the *schausi*, veins are yellowish at the base, the discal band equally broad or posteriorly narrower, proximally not concave as in *caenea*. Expanse 30 to 33 mm. Costa Rica, Colombia, Ecuador.

B. circumlita *Prt.* (70 e). Similar to the following, abdomen with a broad yellow lateral line. In the *circumlita*, forewing a 2 mm broad, posteriorly narrower transverse band with a yellow basal streak and a large subapical patch, beneath all these markings are more distinct. Hindwing yellow, only with a black distal margin. $2\frac{1}{2}$ mm broad at most, being narrower towards the apex and tornus. Expanse 35 mm. Amazons,

- bracteola*. **B. bracteola** *Hbn.-G.* (= *privata* *Wkr.*) (70 e). Forewing with an oblong yellow spot distally to the cross-vein, extending at least to the 2nd median, hindwing black, the costal-marginal third yellow. Beneath the spot of the forewing is expanded to the costal margin, besides there is a yellow cellular spot and a yellow subapical spot. Expanse 35 mm. Colombia, Brazil. — The Venezuelan race ***elongata*** *subsp. nov.* (70 f) has longer and narrower forewings, the costal margin is straighter, the tornus more rounded off, the spot of the forewing above and beneath smaller. Expanse only 28 to 30 mm. ♂ type from Valencia in the Berlin Museum.
- peba*. **B. peba** *Drc.* Forewing blackish-brown with a yellow spot distally to the cross-vein, hindwing blackish-brown with a yellow central stripe, so that the margins, also the costal margin, remain black. Expanse 26 mm. Panama.
- crocearia*. **B. crocearia** *Schs.* Body orange with a black dorsal line on the abdomen. Forewing dark brown with a light yellow spot from the base to beyond the centre. Costal margin and hind-margin dark, the latter with yellow streaks at the edge and on the axillaris, on the yellow area beyond the cell a hyaline spot behind the cross-vein. Hindwing yellow, distal margin and hind-margin black with yellow streaks above the tornus. Expanse 25 mm. Costa Rica.
- subtilis*. **B. subtilis** *Fldr.* (= *punctata* *Drc.*) (70 e). Forewing brown with a yellow spot on the cross-vein, which may extend to the costal margin, veins basally lighter. Hindwing yellow, in the ♀ with a narrow black distal margin, which is narrower in the middle; in the ♂ the black margin is broader and extends also along the hind-margin, where it often contains a yellow stripe. Colombia, Venezuela.
- patinata*. **B. patinata** *Prt.* is similar to *subtilis* and perhaps only a local race of it. In the forewing the light spot extends to behind the fork of the 3rd median. Hindwing as in *crocearia*, the black margin narrower. Expanse 30 mm. Brazil.
- divisa*. **B. divisa** *Dgn.* In the forewing there is beside the discal spot another white cellular spot before the centre of the cell, beneath both spots are orange-yellow. Hindwing similar to *patinata*. In *subtilis* the forewing beneath is yellow except the margin, here only the two spots are yellow. Expanse 26 to 27 mm. Colombia.
- thirmida*. **B. thirmida** *sp. n.* (70 e). According to the description similar to *Thirmida venusta* *Dgn.* The cell in the forewing not so long as half the wing, in both wings posteriorly very much produced. 1st cubitus on a long fork. Forewing yellow, costal margin finely black, hind-margin somewhat broader black. Distal margin at the apex as far as $\frac{1}{4}$ of the wing greyish-black, posteriorly narrower, at the border of the yellow spot jet-black. A black-irrorated basal streak on the analis, one in the cell and a hardly visible one at the costal margin. Hindwing black, with a purple reflection, at the costal margin before the apex a yellow spot, beneath the whole costa as far as this spot is broadly yellow. Bolivia. ♀ type from the Rio Songo in the Berlin Museum. In *Thirm. venusta* the veins in the cell are black.

28. Gattung: **Leptactea** *Prt.*

Cell in the forewing longer than half the wing, 2nd median nearer to the 3rd than to the 1st.

- minuta*. **L. minuta** *Drc.* Forewing jet-black with a yellow transverse band between the costal margin and tornus, but not reaching the distal margin. A yellow basal stripe along the costal margin to its centre, hindwing yellow, margins black. Expanse 32 mm. Ecuador.

29. Gattung: **Actea** *Btlr.*

Facies and palpi with projecting hairs. In the forewing the 2nd radial rises before the 5th before the 3rd and 4th, the 3rd median and 1st cubitus are forked.

- pseudena*. **A. pseudena** *Bsd.* (= *dorsispilota* *Warr.*) (70 f). Black, abdomen with a dorsal row of yellowish spots and lateral yellow lines, wings black, forewing with a yellow transverse band. Mexico to Colombia.
- velutinum*. **A. velutinum** *Btlr.* (70 f) is like *pseudena*, the abdomen without yellow marking. Amazons, Peru, Bolivia.
- monilis*. **A. monilis** *Hbn.* (70 f.). Abdomen with yellow dorsal spots and lateral lines, beneath white. Forewing with two yellow spots transversely behind $\frac{1}{2}$ of the wing, beneath with a yellow transverse band. Hindwing black with a yellow transverse band from the costal margin to the middle of the hind-margin, distally anteriorly expanded. Ecuador, Amazons.
- choba*. **A. choba** *Drc.* (70 f) is quite similar to *monilis*, but in the ♂ there is only a yellow costal-marginal spot, in the ♀ an uninterrupted transverse band. The spot on the centre of the prothorax and hindhead is yellow, in *monilis* white. Amazons.
- transita*. **A. transita** *sp. n.* forms the transition from *choba* to *monilis* (70 f). Dorsal spot on the prothorax yellow, forewing in the ♂ and ♀ with yellow, centrally strangulated transverse band. Somewhat smaller than *choba*. ♂ ♀ types from Para in the Berlin Museum. The last three forms may be the races of one species.

30. Genus: **Josia** Hbn.

The members of this genus exhibit remarkable differences, so that later on it will become necessary to divide them. In the forewing the 2nd radial is forked before the 5th before the 3rd and 4th, the 3rd median and 1st cubitus are forked, the 1st median rising near the radial ramus or being forked with it.

1. The 1st median is not forked with the radial ramus (*Ephialtias* Hbn.).

J. consueta Wkr. (= pilarge Wkr., hyperia Wkr., lugens Fldr.) (67 k). Blackish-brown. thorax in *consueta*. front with a yellow spot, abdomen with 3 white lines, ventrum whitish. Forewing blackish-brown with a yellow transverse band from the costa almost to the tornus. Hindwing uni-coloured blackish-brown. Expanse 35 mm. Amazons. — In **cassa** Prt. the abdomen is without white dorsal lines, the wings with a slight blue lustre, the *cassa*. band of the forewing straighter and narrower. Panama, Colombia.

J. brevifascia Prt. Thorax without the yellow spot at the costal margin, the orange band of the forewing *brevifascia*. is shorter, extending from the radial ramus to right behind the 2nd cubitus. Hindwing with a thin blue lustre, otherwise like the preceding. Amazons.

J. abrupta Hbn. (70 g). Forewing black with a yellow, somewhat bent transverse band as far as *abrupta*. the analis; in the ♀ the hindwing has a short whitish-hyaline band from the hind-margin to the posterior edge of the cell, in the ♂ this white spot is intensely irrorated with blackish. — In the form **basalis** Btlr. the yellow *basalis*. band of the forewing is posteriorly pointed and thus does not end broad on the analis, in the ♀-form **icca** Prt. *icca*. the white spot of the hindwing is irrorated like in the ♂. Amazons.

J. dorsivitta Wkr. (70 g). Black. forewing with a yellow transverse band, hindwing with a white *dorsivitta*. central spot extending to the hind-margin. Amazons, Ecuador.

J. ena Bsd. (= tryma Schs.) (71 g). Forewing blackish-brown with a yellow transverse band. *ena*. hindwing black. The most common species. Venezuela, Trinidad, Amazons, Ecuador, Peru.

J. enoides Bsd. is like the preceding, the band of the forewing is whitish. Mexico, Honduras. *enoides*.

J. infans Wkr. is very similar to *ena* (71 g), the distal margin of the forewing is more oblique, the *infans*. band broader, the projection of the 2nd cubitus yellow, not black as in *ena*. Amazons.

J. ignorata sp. n. (71 f). Wings not so elongate as in the preceding, black, only with a very slight *ignorata*. purple reflection, with a very broad yellow transverse band. Patria unknown; perhaps Colombia. ♀ type in the Berlin Museum. [The 1st median rises separated from the radial ramus!]

2. The 1st median is forked with the radial ramus in the forming. (*Phintia* Wkr.).

J. latifascia Prt. (= lativitta Warr.). Similar to *ena* (71 g). Forewing purple black, the band twice *latifascia*. as broad. Ecuador. A specimen in the Senckenberg Museum, denominated by WARREN as *lativitta*, is an Aretiid! The species may therefore belong to *Josiodes*.

J. esoterica Prt. is similar to *dorsivitta* (70 g), abdomen in the ♀ without white dorsal and lateral *esoterica*. stripes, the band of the forewing is shorter and broader, not extending to the analis, in the hindwing the white basal costal streak is absent beneath, the white central spot is broad and roundish. Expanse 32 mm. Ecuador.

J. tegyra Drc. (70 g) is smaller than the preceding, the wings are narrower, palpi shorter, subcosta *tegyra*. of hindwing less abruptly diverging with the radius. Ecuador.

J. simplex Wkr. is similar to *tegyra* (70 g), the black distal margin of the hindwing only gradually *simplex*. narrowed to the tornus, the white stripe of the hindwing is narrow, short, and does not reach the posterior angle of the cell.

J. jordani sp. n. (70 g) is quite similar to *simplex*, but the white band of the hindwing is more oblique *jordani*. and longer, extending almost to the posterior angle of the cell. Patria unknown. ♀ type in the Berlin Museum.

J. tessmanni sp. n. (70 g). Body black, abdomen beneath dull greyish-white. Forewing black with *tessmanni*. a yellow band which extends barely beyond the 2nd cubitus. Hindwing black with a hyaline white central area which is shorter and rounder in the ♂, narrower and longer in the ♀. The hind-margin remains finely black. ♂♀ types from the Rio Pachitea, East Peru, in the Berlin Museum, discovered by G. TESSMANN.

J. podarce Wkr. (70 g). Forewing black with a short white, somewhat yellowish transverse band. *podarce*. Hindwing also black with a yellowish-white central spot as far as the hind-margin. Amazons.

J. cercostis Wkr. (70 h). Forewing as in *podarce*, hindwing more extensively pale yellow, particularly *cercostis*. in the ♀, the yellow colour is darker than in *podarce*. Amazons, French Guiana, East Peru.

J. ilaire Drc. (71 f). Forewing black, at the base with a slight blue reflection, with a yellow transverse *ilaire*. band 2½ mm broad at most; hindwing black, with an intense blue lustre, particularly towards the base. Panama. — In **turbida** subsp. n. (71 f) the band of the forewing is at least 3 mm broad, the lustre on the *turbida*. hindwing is less intense, more reddish-violet. Colombia. ♀ type from the Rio S. Juan in the Berlin Museum.

J. repetita Warr. (71 f) is similar to *ilaire*, but larger, the hindwing with a yellow apical spot, *repetita*. Colombia.

3. Larger species, the apex of the forewing more roundish.

- draconis*. **J. draconis** Drc. (70 h). Forewing blackish-brown, with a broad yellow postcellular transverse band, which is so oblique that the posterior part of the cross-vein does no more touch the band which is somewhat expanded at the costal margin. Hindwing red, distal margin and costal margin narrower, hindmargin broad black. Panama. — In **tenuifascia** Prt. the band of the forewing is narrower ($1\frac{1}{2}$ mm) and anteriorly scarcely widened. British Guiana.
- bryce*. **J. bryce** Wkr. (70 h) is similar to the preceding, the band of the forewing steeper, touching the cross-vein in all parts. Amazons. Perhaps only a form of the preceding.
- rosea*. **J. rosea** sp. n. (70 h) approximates the preceding, it is somewhat smaller, the band of the forewing flesh-coloured or red, beneath more yellow. In the hindwing the base is broader black, the proximal border of the black posterior margin diverges very much with the posterior edge of the cell. Abdomen as in the preceding, the first segment with a large yellow dorsal spot, the row of dorsal spots on the other segments is more interrupted. Expanse 30 to 32 mm. District of the Upper Amazon River. ♂♀ types from Itaituba in the Berlin Museum.
- ariaca*. **J. ariaca** Drc. Forewing black with a yellow transverse band. Hindwing with a narrow yellow central transverse band to the hind-margin. Expanse 26 mm. Mexico.
- coatepeca*. **J. coatepeca** Schs. (67 k) is similar to *ariaca*, larger, the bands on the forewing and hindwing broader. Expanse 29 mm. Mexico, Honduras.
- latistriga*. **J. latistriga** sp. n. (70 i) has the size of *coatepeca*, with broader stripes on the hindwing, occupying the hind-margin except the outermost base. Band of forewing more bent than in the preceding. ♀ type from Marcapata in the Berlin Museum.
- constricta*. **J. constricta** Warr. (70 i) is similar to the following, somewhat smaller, the yellow central longitudinal spot in the hindwing at the base reduced into a narrow bow, the distal part more rounded and ending farther before the distal margin than in *vittula*. Expanse 32 mm. Bahia.
- vittula*. **J. vittula** Hbn. (70 i). Forewing black with a yellow oblique transverse band, hindwing black with a yellow longitudinal band which rises at $\frac{1}{4}$ of the hind-margin and leaves the base black. — In f. **carneata** *adiante* Warr. the yellow markings are flesh-coloured. Brazil. — The Colombian race is **adiante** Wkr. (70 i) in which the forewing and the band are narrower, the band more oblique, rising before the middle of the costa. The yellow central area of the hindwing is broader and more uniformly wide, the yellow markings are deeper orange. As this form flies also in Brazil with *vittula*, it may represent a separate species.
- aperta*. **J. aperta** Warr. (70 i). The band of the forewing is broader and steeper, in the hindwing the hind-margin, except the base, is yellow as far as the tornus. Peru, Bolivia.
- fornax*. **J. fornax** Drc. (70 k). The yellow transverse band of the forewing is distally not bent, steep and straight. Hindwing extensively yellow, apex and distal margin black, the latter towards the tornus much narrower. Expanse 40 mm. The ♀♀, according to WARREN, show a twice as broad black distal margin of the hindwing, the same is the case in the ♂-form **latimargo** Warr. Ecuador.
- latimargo*. **J. latimargo** Warr. (70 k). The yellow transverse band of the forewing is distally not bent, steep and straight. Hindwing extensively yellow, apex and distal margin black, the latter towards the tornus much narrower. Expanse 40 mm. The ♀♀, according to WARREN, show a twice as broad black distal margin of the hindwing, the same is the case in the ♂-form **latimargo** Warr. Ecuador.
- morena*. **J. morena** Warr. (70 h). Forewing blackish-brown, veins somewhat paler, with a yellow transverse band. In the hindwing the yellow central band rises from $\frac{1}{2}$ of the narrow black hind-margin, being distally widened and rounded off. Brazil, Rio Grande do Sul; one specimen from Bolivia.
- angulosa*. **J. angulosa** Wkr. (70 k) is similar to *morena*, the yellow band of the hindwing broader, almost square, sharply angled at the 2nd cubitus. Brazil.
- eterusialis*. **J. eterusialis** Wkr. (70 k). Forewing with a very broad (5 mm) transverse band, the yellow area of the hindwing still broader than in *angulosa*. Colombia.
- flavissima*. **J. flavissima** Wkr. (70 k) is similar to *eterusialis*. Wings changing from sulphur-colour to lemon-colour instead of orange. Venezuela, Ecuador.

4. Forewing with longitudinal stripes (*Josia* Hbn.).

- megaera*. **J. megaera** Hbn. (= *fasciata* Roths.) (71 a). Forewing blackish-brown, with a yellow streak behind the cell, mostly extending into it, and a yellow subapical band which does not reach the margins. Hindwing blackish-brown, hind-margin and a marginal spot behind the 2nd cubitus yellow. The yellow hindmarginal colouring extends to the analis. — In **integra** Wkr., from Mexico, Honduras, and Guatemala, the yellow markings in the hindwing are connected, the indentation through the black analis is absent. — In **decorata** Drc. the subapical band is longer, almost reaching the margins. — **fruhstorferi** Prt. from Bahia has all the markings in the forewing narrower, the basal stripe scarcely reaches the posterior edge of the cell. — In **putata** subsp. n. the yellow hind-margin of the hindwing extends only to the axillaris and does not reach the analis. Amazons. ♂♀ types from Para and Obidos (HAHNEL) in the Berlin Museum.
- auriflua*. **J. auriflua** Wkr. (71 a). Forewing black with an orange longitudinal stripe which ends very near at the distal margin (1 mm). Hindwing black with a yellow posterior margin which cuts the 2nd cubitus before the centre. Panama, Colombia. — In **flavipars** Prt. (71 a) the posterior margin of the hindwing is narrower and cuts the 2nd cubitus in or behind the centre. Bolivia, East Peru. — The following two races may be distinct

species; they both exhibit the broader posterior margin of the hindwing of the nomenclatural form; the streak of the forewing is broader and its anterior edge at the end obtusely angled, not uniformly bent as in the preceding.

— In *scalata* Dgn. (71 a) it ends at the same distance from the margin as in *auriflua*; — in *inaequiflexa* (71 a) *scalata*, it ends before, about $1\frac{1}{2}$ mm before the margin. The former is from Peru, the latter from Ecuador. *inaequiflexa*.

J. aurifusa Wkr. A most variable species. Forewing blackish-brown with an orange central stripe, *aurifusa*, which is narrower at the end. In the nomenclatural type the hindwing is yellow, the apex black which colour taperingly extends to the base; — in *turgida* Warr. (71 b) the black apical colouring in the hindwing only *turgida*, extends narrower to the centre of the wing, between the 2nd cubitus and axillaris a black spot at the margin; in the form *conifera* Warr. the orange central spot of the forewing has distally a coniform continuation; in *conifera*, the hindwing the apical spot is continued to the base, connected with the black spot behind the 2nd cubitus by a broad black space. — The form *glycera* Drc. has a broad black costal margin in the hindwing, in which *glycera*, only the outermost edge remains yellow. Venezuela, Brazil, Colombia, Panama.

J. subcuneifera Dgn. seems to me to be a form or race of the preceding species. Forewing as in *aurifusa*. *subcuneifera*, hindwing also similar; beneath in the forewing the central band is enlarged, extending to the distal margin. on the hindwing only a longitudinal streak on the subcosta, the apex and a spot at the 2nd cubitus remain black (like in *turgida* (71 b)). Expanse 30 to 35 mm. Ecuador.

J. lativitta Wkr. (71 b). Forewing blackish-brown with a broad yellow longitudinal stripe, which *lativitta*, is narrower at both its ends and does not reach the distal margin. Hindwing likewise blackish-brown with a broad yellow longitudinal streak. Amazons.

J. ligula Hbn. (= *fulvia* Cr.) (71 b). Blackish-brown, central area of both wings and hind-margin *ligula*, of the hindwing yellow. The width of the yellow markings varies. From Guiana and Brazil to Bolivia, Ecuador, and Peru.

J. oribia Drc. (= *schmusei* Strd.) (71 b) is quite similar to *ligula*, the yellow areas are much broader. *oribia*, so that the wings are yellow narrowly bordered with black. Bolivia.

J. tenuivitta Btlr. Like the preceding, the yellow markings narrower, particularly in the forewing. *tenuivitta*, Amazons, Guiana, Ecuador, Peru.

J. infausta sp. n. (71 b). Forewing broader, in the shape more similar to *mononeura* (71 c). Forewing *infausta*, blackish-brown with a yellow longitudinal streak as in *tenuivitta*. Hindwing with a streak as in *ligula*. Expanse 31 mm. Colombia. ♀ type from the Rio S. Juan in the Berlin Museum.

J. cruciata Btlr. The first abdominal segment above with a yellow ring. Streak of forewing very *cruciata*, narrow, that of hindwing begins here and in the following species not at the base, but at $\frac{1}{3}$ of the hind-margin. Streaks of both wings almost equally broad. Central America to Brazil and Peru.

J. annulata Dgn. (= *pnnonis* Strd.) (71 d) is probably the same species as *cruciata*, with a broader *annulata*, streak of the hindwing. Range like that of *cruciata*.

J. tamara sp. n. (71 d) is very closely allied to *annulata*, the yellow bands are in both wings broader. *tamara*, extending almost to the margin. There remains but a very fine margin black (in *annulata* the yellow band ends $\frac{3}{4}$ mm before the margin). Base of abdomen with a yellow ring, fringe at the hind-margin of the hindwing yellow. Honduras, ♀ type in the Berlin Museum.

J. aurimutua Wkr. (? = *fulvia* Hbn., ? *jesuita* F.) (71 e). Similar to *cruciata*, fringe at the hind- *aurimutua*, margin of the hindwing black. Panama, Venezuela, Ecuador, Brazil.

J. interrupta Warr. (71 a). The yellow stripe of the forewing is centrally sometimes interrupted by *interrupta*, black scaling, the ground-colour of the forewing is brown, not black, though not so light as in the next species, the streaks on both wings pale yellow, still narrower than in *tenuivitta*. Expanse 36 mm. Colombia.

The three following species with an olive-brown ground-colour of the forewing.

J. mononeura Hbn. (= *mitis* Wkr.) (71 e). The streak of the forewing is very narrow, posteriorly *mononeura*, with short projections on the cubital branches. Abdomen beneath blackish-grey. Brazil, Colombia, Uruguay.

J. similis sp. n. is coloured the same, but the abdomen beneath is white, somewhat smaller. Para. *similis*, 2 ♂♂. 1 ♀ in the Berlin Museum.

J. insincera Prt. (71 b). Streak of forewing broader, posteriorly hardly with projections, abdomen *insincera*, beneath white. Venezuela, Orinoco District.

The 7 following species show the costal margin of the forewing finely yellow in the basal half.

J. ligata Wkr. (71 d). Wings blackish-brown with moderately broad yellow streaks, on both wings *ligata*, about equally broad. Central America, Venezuela, Colombia.

- frigida*. **J. frigida** Drc. (71 d). This and the following species are presumably only forms of the preceding, connected by all kinds of transitions. Streaks of forewing and hindwing narrower. Central America, Guiana, Colombia, Ecuador.
- fustula*. **J. fustula** Warr. has the streaks in both wings almost equally broad; smaller than the preceding ones. Ecuador.
- radians*. **J. radians** Warr. (= ? *fulvia* Drc.) (71 d). Streaks still narrower, particularly in the forewing. Mexico to Venezuela and Guiana.
- fusigera*. **J. fusigera** Wkr. (= *fusifera* Drc.) (71 e) is larger than the preceding, the streaks, particularly in the hindwing broader. I still doubt whether it is a distinct species, or only a form of *ligata*. Mexico to Colombia.
- gigantea*. **J. gigantea** Drc. (71 e) is similar to *radians*, but considerably larger. Expanse about 45 mm. Panama, Costa Rica.
- flexuosa*. **J. flexuosa** sp. n. (71 e) is about the size of *fusigera*, the streaks are very much broader, that of the forewing at 2_3 anteriorly distinctly convex, then much narrower. The black hind-margin of the hindwing is at the broadest place only 2 mm broad, in *fusigera* broader. Mexico. ♂♀ types in the Berlin Museum. — A ♀ from Honduras has in both wings narrower streaks, but that of the forewing has the curve at the costal margin. Thus the specimen approximates *ligata* and may represent a separate race which is called **diminuata** subsp. n. (71 e).

The following species with a black costa of the forewing, larger species.

- striata*. **J. striata** Drc. (71 e). Three quarters of the streak of the forewing are broad, then suddenly narrower by strangulation at its posterior edge. Streak of hindwing posteriorly much broader, extending to the hind-margin, which is yellow as far as the tornus. Expanse 38 to 40 mm. Colombia, Ecuador.
- attenuata*. **J. attenuata** Warr. (71 d) is like the preceding, the streak of the forewing is uniformly narrower, not suddenly narrowing down. The black posterior margin of the hindwing is broader, extending to about half the hind-margin. Colombia.
- ampliflava*. **J. ampliflava** Warr. (71 e). Streak of forewing as in the preceding, the posterior margin of the hindwing very narrow, 2 mm broad on an average. Colombia.
- andosa*. **J. andosa** Drc. is similar to *striata* (71 e), larger. Expanse 50 mm. Colombia.
- longistria*. **J. longistria** Warr. is similar to *patula* (71 e), larger (expanse 44 mm). Hindwing yellow, costal margin and posterior margin narrowly black, broader at the apex and before the tornus. Ecuador.
- patula*. **J. patula** Wkr. (71 e). Streak of forewing broad, shortened, ending already at $\frac{1}{4}$ of the 3rd median. Hindwing yellow, uniformly margined with black; this margin narrows down to a dot on the tornus. Expanse 38 mm. Colombia.
- gephyra*. **J. gephyra** sp. n. (71 f) is between *patula* and *gopala*. Streak of forewing somewhat less expanded than in *gopala*, extending to behind the rise of the 2nd cubitus beyond the analis. Hindwing as in *patula*. A smaller species, expanse 30 mm. Colombia. ♂ type from Tolima in the Berlin Museum (FASSEL).
- gopala*. **J. gopala** Dgn. (71 d). Streak of forewing very much distally expanded, broadly truncated. Venezuela.
- fluonia*. **J. fluonia** Drc. (71 f). Forewing black with a yellow, angularly curved band extending below the costal margin as far as 2_3 , then bending round to the tornus in an obtuse angle. The band is 2 mm broad at most and widens little. Hindwing black. Ecuador.
- banana*. **J. banana** Warr. (71 f) resembles the preceding, the band of the forewing is very much broader, the angle of the curve in the ♀ much obtuser, in the ♂ even the posterior edge of the stripe extends rather straight from the base to the tornus. „Brazil“.

31. Gattung: **Seca** Wkr.

Distinguished from *Josia* by the 1st median of the forewing being always well separated from the radial ramus and the 2nd median not rising at the mouth of the basal median, but behind it, whereby the cross-vein is twice angled (except *obliquaria*). Faeies and palpi not rough-haired.

- auriflamma*. **Sc. auriflamma** Hbn. (= *nervosa* Perty) (71 g). Forewing reddish-yellow, costal margin, veins, hind-margin narrower, apex broader black, distal margin narrower towards the tornus. Hindwing black. Brazil, Bolivia, Paraguay, North Argentina.
- obliquaria*. **Sc. obliquaria** Warr. (71 g). Cross-vein of forewing but once angled, veins less black, the proximal border of the black apical margin is more oblique, straighter; hind-margin broader black. South Brazil, East Peru.
- solaris*. **Sc. solaris** Schs. (71 g). Forewing and veins black, a yellow central spot almost to the distal margin. Its anterior edge extends as far as about 2_3 along the costa and then bends round to the 3rd median. Hindwing black with a narrow yellow central stripe which, in a Bolivian specimen, despatches a tooth towards the costa. Peru, Bolivia.

Sc. nudata *sp. n.* Similar to *auriflamma*, veins not black, the posterior edge of the cell at most; *nudata*. apical margin more extensively black, beginning already at $\frac{2}{3}$. „Brazil“ (Sello). ♂♀ types in the Berlin Museum.

Sc. angustimargo Warr. (71 g). Forewing yellow, veins everywhere black, also blackish scales on *angustimargo* the ground-colour. The black apical area is narrower and more curved. Hindwing black, beneath with a few yellow basal streaks at the costal margin. Bolivia, Peru, Paraguay.

Sc. cleonica Drc. (71 g). Forewing yellow, costal margin and hind-margin narrow, apical area as *cleonica*. far as the cell black, likewise blackish irroration on the ground-colour. Hindwing black, all the black places with a slight purple reflection. Ecuador.

Sc. semifulva Warr. (71 g). Similar to *cleonica*, the yellow colour more reduced, not reaching to the *semifulva*. cross-vein. Ecuador.

Sc. curvilimes *Prt.* The dark apical area of the forewing extends proximally at the cross-vein to the *curvilimes*. posterior angle of the cell, and behind it is strongly curved towards the distal margin. Expanse 38 mm. North Peru.

Sc. gigantea Drc. (= *caesiopicta* Warr.) (71 h) looks like a gigantic *auriflamma*; in the forewing *gigantea*. the apical area except the border towards the yellow area and the anal margin of the hindwing bluish-grey, in the smaller ♂ more indistinct. Bolivia. — In *subcyanea* *Prt.* (= *cyanea* *Prt.*) the bluish-grey areas are intensely suffused with blue; in the ♀ the posterior parts of the hindwing are less light. South-Eastern Peru.

Sc. servula Warr. (71 h) is likewise similar to a very large *auriflamma*, the black places are somewhat purple, but not bluish-grey, the analis and media not black. Colombia, Peru. — **steinbachi** *Prt.* is smaller (expanse 38 to 42 mm), veins black as in *auriflamma*. Argentina. The latter race is discernible from large specimens of *auriflamma* by the 2nd media rising very near to the third.

Sc. erasa *Prt.* (71 h). Similar to *servula*, veins in the yellow area of the hindwing nowhere black. Colombia, East Peru. It corresponds to *Crocomela trigonata* Warr. (p. 453) flying at the same places.

Sc. vulturata Warr. (71 h). Forewing blackish-brown with a yellow longitudinal band which is curved towards the tornus. Hindwing blackish-brown with a yellow basal spot. East Peru. It corresponds to *Crocomela conscita* Drc. (p. 453).

32. Genus: **Thirmida** Wkr.

Veins as in *Scea*, face, palpi, and hind femora with rough hair.

Th. dimidiata Wkr. (71 h). Forewing yellow, costal margin, hind-margin, veins, and apical portion behind the cross-vein black, the apical portion suffused with bluish-grey. Hindwing yellow, margins narrow, apex very broadly purple black, on the cross-vein in both wings a black spot. Colombia. — In **discinota** Warr. (71 i) the black apical portion of the forewing is broader and encloses the cross-vein. Venezuela.

Th. grandis Drc. (71 i). Forewing as in *discinota*, in the hindwing the base is black, the apical portion very much broader, enclosing the cross-vein. Colombia.

Th. circumscripta *sp. n.* (71 i). Forewing yellow, margins and veins narrowly black, in the apex a large circular spot. Hindwing yellow, margins very narrowly black. Beneath the yellow places also in the forewing without black veins, on the cross-vein a black spot. ♂ type from Colombia in the Berlin Museum.

Th. superba Drc. (71 i). In the habitus similar to *Scea servula* (71 h), in the forewing the black apical portion is more extensive, enclosing the cross-vein. Ecuador.

Th. venusta Dgn. is like *superba*, hindwing at the costa above partly yellow, beneath broadly yellow as far as $\frac{3}{4}$, the yellow colour of the forewing beneath extending farther distally. Ecuador.

More densely covered with longer hair than in the preceding genus. Suffused with blue.

33. Genus: **Cyanotricha** *Prt.*

C. necyria Fldr. (71 i). Black, suffused with blue, below the costa of the forewing some red short basal streaks. Ecuador, Peru.

C. bellona Drc. Like *necyria* (71 i), but with an oblong red spot before the apex of the forewing. Peru.

34. Genus: **Sagaris** Wkr.

In the forewing the 2nd radial rises before the 5th, before the 3rd and 4th; the costal margin of the hindwing is strongly curved, ♂ with scent-spots on the hindwing.

S. rejecta Hbn. (= *stygne* Wkr., *erynnis* Wkr.) (71 i, k). Black, forewing with a yellow transverse band the edges of which are undulating. Brazil Venezuela. — The Colombian specimens were denominated: **ortropea** *ortropea*.

Drc.; they have a narrower band of the forewing, though there occur all kinds of transitions to the type, so that the race is hardly tenable. Also from Bolivia.

poliana. **S. poliana** *Drc.* (71 k). Like the preceding species, with white, broader, hardly undulating bands, hindwing somewhat purple blue. In the Berlin Museum there is also a ♂ from Massauary, corresponding to the ♀, the shape of the body similar to *rejecta*. Guiana, Amazons.

dilatata. **S. dilatata** *Wkr.* (71 k). In the forewing the 1st eubitus is forked, in contrast with the preceding species. Abdomen not extending beyond the hindwing. Forewing oblong rounded, veins lighter. Amazons.

35. Genus: **Getta** *Wkr.*

In the hindwing the radial ramus and the 1st median are fused. The cell of the forewing in the ♂ is very short and narrow, hindwing with a scent-organ at the costal margin, also the 2nd median fused with the 1st.

ennia. **G. ennia** *Drc.* Black with a pale yellow cross-band of the forewing. Brazil.

elite. **G. elite** *Wkr.* (= *niveifaseia* *Wkr.*) (71 k). Like *ennia*, cross-band white. Brazil, Ecuador, Bolivia, Southern Peru. — **probles** *Prt.* is larger, the cross-band is twice as broad. Eastern Peru.

bactifica. **G. bactifica** *Drc.* (71 k). Cross-band yellow, wings partly suffused with blue. Colombia, Peru, Ecuador.

36. Genus: **Anticoreura** *Prt.*

In the forewing the 5th radial rises before the 2nd; 1st eubitus not forked.

salmoni. **A. salmoni** *Drc.* Forewing blackish-brown, with a red cross-band, hindwing black, suffused with blue. Colombia. It strikingly resembles certain Syntomidids (*Coreura*).

37. Genus: **Polyptychia** *Fldr.*

In the forewing the 5th radial rises before the 2nd; 1st eubitus forked. ♂ with scent-tufts on the hindwing and hind legs.

fasciculosa. **P. fasciculosa** *Fldr.* Blackish-brown, forewing with a yellowish-white cross-band. Colombia, Venezuela.
ccron. — In **ccron** *Drc.* (71 k) the band is yellow; in the ♀ at the apex of the hindwing a yellow spot. East Colombia,
unicolor. Upper Amazon R. — In **unicolor** *sp. n.* (perhaps only a form of *ccron*?) the yellow band of the forewing is 3 mm broad (in *ccron* 2 mm). Hindwing above and beneath without the yellow apical spot. ♀ type from Yurimaguas in the Berlin Museum.

6. Family: Lymantriidae.

The general characterisation of the family of the *Lymantriidae* has been so minutely particularised in Vol. II, S. 109, Vol. X, p. 291, and Vol. XIV, p. 127, that it is unnecessary here to touch all the questions once more. We merely recapitulate that the genuine *Lymantriidae* are essentially characterised by the absence of the proboscis; moreover these insects are easily discernible by the basal anastomosis of the costalis in the hindwing, the presence of the frenulum, and the origin of vein 5 of the hindwing near the lower cell-angle. In America the limits are partly somewhat obliterated by the appearance of forms exhibiting also close relations to other families, such as the *Pericopidae* and *Geometridae*. We refer here particularly to the genera *Animomyia* Dyar and *Eloria* Wkr., the former being placed to the *Geometridae* by PEARSALL and MC DUNNOUGH, whereas the latter genus often exhibits a feebly developed proboscis, though only in one sex, for which reason it is partly to be assigned to the *Pericopidae*. Owing to the absence of the proboscis, which fact signifies that they feed on flowers, we may assume a phylogenetically very old age.

As to the distribution of the *Lymantriidae* in the New World, the northern continent only possesses, beside the quite different small species of *Animomyia*, such genera that entirely correspond to the palearctic species of *Dasychira* and *Orgyia*, of which only the latter proceed down to southern latitudes. In Central and South America we meet with quite different forms which partly resemble externally the *Geometridae* or *Pericopidae*, but which partly also exhibit a remarkable convergency to African *Stilpnotia*, such as the silvery white *Caviria*; on the other hand, we also find quite different types, particularly among the genera without an areola, which, as for instance the *Desmoloma*, most decidedly resemble Notodontid groups, the *Phiditia* and *Rolepa*-species the allies of *Apatelodes*. Thus the family creates in the New World a much more heterogeneous impression than in other faunal districts.

As far as the early stages are known, they are here quite the same as we are used to find in the palearctic *Lymantriidae*; knobbed tubercles, pencils, and brushes are inserted in the general hairy coating, partly with an inflammatory effect. Some of them live on conifers. About the early stages of the more southern forms we know almost next to nothing.

The elaboration of this difficult family by Dr. SCHAUS and the most perfect reproduction of the insects by the master-hand of Mr. FRANCIS H. NOYES, most of which have never been figured before, means an enormous progress in the information about this family, particularly since there had so far only existed detached publications about it from the American faunal district. The arrangement in KIRBY's Catalogue is of no use whatever, as it contains a most varied collocation of insects from all kinds of families that were thrown together here.

We feel infinitely indebted to Dr. L. O. HOWARD, the Director of the Entomological Division of the National Museum in Washington, by whose great obligingness we were enabled to published such a unique material of figures as will probably never again be possible for any other work. Some new species from the Berlin Museum have been inserted by myself, in accordance with Dr. SCHAUS to whom I had submitted them. (Dr. DRAUDT.)

It is preferable to use the family name as employed already by STRAND, Vol. II, p. 159, who gives an interesting outline of it. The American species are not very numerous in comparison to the Oriental and African forms. Unfortunately three of the most injurious species, *Porthetria dispar*, *Nygmia phaeorrhoea* Don., and *Stilpnotia salicis* L. have been introduced into the United States where they are doing considerable damage. Eventually the genera *Eloria* Wkr. and *Animomyia* Dyar will have to be transferred to a new family intermediate between the *Pericopidae* and *Lymantriidae*. (Dr. W. SCHAUS.)

Analytical Table of Genera.

Group I: *Areolatae*.

(Forewing with a more or less developed areole.)

A. Palpi porrect.

a. Hind tibiae with one pair of spurs.

a¹. Antennae pectinated with terminal bristles.*Notolophus*.b¹. Antennae pectinated without terminal bristles.*Byrdia*.

b. Hind tibiae with two pairs of spurs.

a¹. Legs hairy.*Hemerocampa*.b¹. Legs smooth.*Animomyia*.

B. Palpi upturned.

a. Hind tibiae with one pair of spurs.

a¹. Forewing with vein 11 free*Eloria*.b¹. Forewing with vein 11 connected with subcostal by a bar or anastomosing with 10 to form areole.*Caviria*.

b. Hind tibiae with two pairs of spurs.

Olene.Group 2: *Inareolatae*.

(Forewing without areole.)

A. Hind tibiae with one pair of spurs.

a¹. Forewing with veins 7—9 stalked.a². Hindwing with veins 3 and 4 from cell.*Stilpnobia*.b². Hindwing with veins 3 and 4 on long stalk.*Phreata*.b¹. Forewing with 7—10 stalked.*Thagona*.

B. Hind tibiae with two pairs of spurs.

a¹. Forewing with veins 7—9 stalked.a². Apex of forewing rounded.*Sarsina*.b². Apex of forewing acute.*Staetherinia*.b¹. Forewing with veins 7—10 stalked.a². Vein 10 given off before 7.*Porthetria*.b². Vein 10 given off beyond 7.*Nygma*.e¹. Forewing with 7 and 8 stalked 9 absent.*Blazia*.d¹. Forewing with 7 and 9 absent in male.*Desmoloma*.e¹. Forewing with 7 absent, 8—10 stalked.a². Hindwing erenulate.*Phiditia*.b². Hindwing not erenulate.a³. Apex of forewing slightly produced.*Phecada*.b³. Apex of forewing not produced.a⁴. Termen of hindwing rounded.*Rolepa*.b⁴. Termen of hindwing straight.*Sorocaba*.

Note: Not included the somewhat doubtful genus: *Aza Wkr.* and the genus *Leuculodes Dyar*, which belongs to the Pericopidae.

1. Genus: *Notolophus* Germar.

Male. —Palpi porrect with rather long hairs. Antennae with long branches, bipectinate, and with terminal bristles. Legs hairy with a single pair of spurs on hind tibiae. Forewing: vein 2 well before lower angle; 3 near angle; 4 and 5 slightly apart from angle; 6 from upper angle; 7, 8 and 9, 10 from areole; 11 free. Hindwing: veins 3 and 4 from lower angle; 5 above angle; 6 and 7 stalked.

Type of genus, *antiqua* Linn.

antiqua. *N. antiqua* L. (= nova Fitch). Vide Seitz Vol. II, p. 117. The species is widely distributed in northern *badia*. United States. — Ab. *badia* Hy. Edw. (72a) has the basal and terminal areas heavily shaded with blackish brown.

2. Genus: **Byrdia** *n. gen.*

♂. Antennae bipectinate without terminal bristles. Palpi porrect clothed with long hairs. Legs very hairy, hind tibiae with a single pair of short spurs. Forewing: venation as in *Notolophus*, the areole long and narrow. Hindwing: vein 2 before angle; 3 and 4 approximated at base or shortly stalked; 5 slightly above angle; 6 and 7 from upper angle or shortly stalked.

Named in honour of Commodore BYRD, first man to fly to the North Pole.

Type: *Byrdia rossii* Curtis.

B. rossii Curtis (72 a). Male. — Body above slate colour, underneath mottled with light neutral *rossii*. grey. Forewing grey irrorated with drab, less so on basal third; lines black; a broken subbasal line; ante-medial line sinuous, well defined; postmedial fine, irregular, partly followed by a black shade; subterminal black shade more irregular than in figure, outwardly with a diffuse white shade. Hindwing cream colour, the margins broadly black and the veins partly fuscous. Arctic America.

B. groenlandica Home. Male with much narrower wing, black mottled with grey. The male in Nat. *groenlandica*. Mus. in very poor condition, the wings rubbed and partly distorted. Greenland.

2a. Genus: **Aza** Wkr.

The type of this genus described by WALKER in Cat. Lep. Het. B. M. 32, p. 384 is lost as kindly communicated by Mr. TAMS. The description says: Male: body slender; proboscis absent; Palpi short, slender, porrect, acute, not surpassing the head; antennae very largely bipectinate. Legs slender, rather short. Wings thinly scaled, semihyaline, anterior wings with the apex rounded, hindwings much longer than the abdomen.

Type: *A. micacea* Wkr.

Druce described a second species as *Aza*; according to the communication of Mr. TALBOT the type, now in the Hill-Museum, is a Lymantriid and is to be inserted here:

A. eutelida Drc. Male. — Head, antennae and thorax pale brown; abdomen white; legs yellow. Primaries *eutelida*. white, the costal and outer margin edged with yellowish-brown; secondaries white. Expanse: 1 1/4 inch. Hab. Sarayacu, Ecuador. Talbot writes that the hind-tibiae have one pair of spurs. If the drawing he sent is correct it shows an areole which would bring it in the same group as *Notolophus* and *Byrdia* which are northern species.

3. Genus: **Hemerocampa** Dyar.

Differs from *Notolophus* in having a single pair of spurs on hind tibiae. Female with wings aborted. The species all offer considerable variation and are more easily separated by the larvae.

Type: *H. leucostigma* Sm. & Abb.

H. leucostigma S. & A. (= *leueographa* Geyer, *intermedia* Fitch, *borealis* Fitch, *obliviosa* Hy. Edw.) *leucostigma*. (72 a). Forewings light drab suffused with pale brown; antemedial irregular darker shaded from costa to median vein; postmedial line fine; outcurved below costa, followed by a dark costal spot; the white spot near angle very small or obsolete. Hindwing drab with pale eilia. In some specimens all the markings are very faint. Atlantic States.

H. vetusta Bsd. (72 a). Forewing brown, the two lines black well defined, the white spot at inner *vetusta*. angle distinct; hindwing brown, the termen darker shaded. — Ab. **gulosa** Hy. Edw. (72 a) smaller, the lines *gulosa*. more confused; white spot at inner angle smaller. — Ab. **cana** Hy. Edw. (72 a). Forewing greyish, the two *cana*. lines black, distinct, the white spot at angle very faint or absent; hindwing brown, paler than in typical species. California to Alaska.

H. plagiata Wkr. (72 a). Forewing reddish brown; a broad fuscous subbasal space, followed by a *plagiata*. faintly wavy thick black line, finer and incurved on inner margin; medial space from costa to median vein whitish containing a slightly oblique discal spot finely outlined with black; postmedial line black, finely wavy, outcurved beyond cell, inbent to inner margin; a subterminal whitish line defined by black, slightly curved at eosta. Hindwing fawn colour. Described from unknown locality.

H. inornata Beut. (72 a). Also rather variable, the larva very distinct, approaching that of *leuco-* *inornata*. *stigma*. Forewing mottled drab and brown, the lines more broadly dark shaded, the reniform space whitish crossed by black lines; the white spot near inner angle almost or entirely obsolete. Hindwing drab shaded with brown. Atlantic States.

- oslari*. **H. oslari** Barnes. ♂. Forewing light yellow brown suffused with darker brown, lines black; basal line distinct; antemedial line distinct, outcurved; postmedial line crenulate, oblique to beyond cell, then incurved to inner margin inwardly preceded by a blackish shade on costal half; termen with three black dashes opposite cell; a white spot near angle; reniform surrounded by a ring of blackish scales. Hindwing blackish brown like darker shades of forewing. Colorado.
- pseudotsugata*. **H. pseudotsugata** B. & McD. (72 b). ♂. Forewing verona brown, thickly irrorated with whitish scales giving an iron grey tone to the wing; lines black, the antemedial straight or somewhat outbent on inner margin, the postmedial outcurved around cell, incurved above inner margin; dark terminal streaks between veins beyond cell; a white curved spot above inner angle. Hindwing snuff brown, the termen broadly dark shaded. California.
- definita*. **H. definita** Pack. (72 b). ♂. Forewing mouse grey, suffused with fuscous, the lines black; a distinct dark subbasal line; antemedial line sinuous accompanied by a broad dark shade on costal half; postmedial fine, outcurved and thicker beyond cell, well incurved from below vein 4; reniform incurved on a white irrorated ground, defined by fine dark lines; veins 6 and 7 white with dark interspaces; a faint white subterminal line, more distinct from below vein 3 to near inner margin; a dark irregular terminal line inwardly faintly white edged. Hindwing mouse grey suffused with fuscous. Atlantic States.
- falcata*. **H. falcata** Schs. (72 b). ♂. Body grey. Forewing with basal third brownish grey limited by a velvety fuscous line; a similar line at base; medial and terminal areas grey suffused with drab; postmedial line finely lunular fuscous black, outcurved beyond cell enclosing a fuscous space; a pale subterminal wavy line defined by drab; a dark terminal line, lunular below vein 3; cilia dark with a pale line at base. Hindwing drab with darker suffusions and a fine dark terminal line. Figured in Biologia. Jalapa, Mexico.
- guatemalteca*. **H. guatemalteca** Schs. (72 b). ♂. Forewing buffy brown, darkest at base; lines as in *falcata* Schs., the postmedial enclosing a conspicuous fuscous black spot; subterminal line fuscous black with projecting teeth basad from costa to vein 4, then forming diffuse spots parallel to postmedial line; a dark terminal line and pale shade at base of cilia. Hindwing cinnamon drab suffused with hair brown; the base with pale suffusions. Guatemala..
- colombiensis*. **H. colombiensis** Dogn. (72 b). ♂. Forewing to postmedial line whitish irrorated with light greyish olive; an interrupted fuscous black subbasal line, slightly outbent, followed by a broad smoky drab shade, its outer edge lunular; antemedial line almost vertical, fuscous; postmedial line, fine, black, minutely lunular, outcurved beyond cell enclosing a buffy olive shade, which is preceded by the narrow, oblique white reniform; an oblique dark spot on costa beyond postmedial, cut by white veins; terminal space mostly light brownish olive crossed by a faintly darker line; an irregular dark marginal line. Hindwing whitish suffused on outer half with drab, the subterminal dark line of underside seen in transparency. Pacho, Colombia.
- costaricensis*. **H. costaricensis** Schs. (72 b). ♂. Body buff, the thorax mottled with darker scales; dorsal tufts of early dark and metallic scales on basal half of abdomen. Forewing: basal third mottled buff and brown, limited by a slightly oblique dark brown antemedial line, and containing an interrupted black basal line and a large ovate brown spot below the cell; costa between lines creamy buff; a steel grey medial shade from subcostal to submedian, and within curve of postmedial line; two brown lines at end of cell; postmedial line outcurved beyond cell, incurved below vein 2, thick, black, lunular, followed at apex by some black and buff; termen light brown partly shaded with grey; sometimes a dark terminal line. Hindwing buff with some dark marginal shading at apex. Tuis, Juan Viñas, Costa Rica.
- coresia*. **H. coresia** Drc. (72 b). ♂. Body and wings saecardo's umber. Forewing: a slightly darker space on basal half from costa across cell, then inbent to near base of inner margin; a similar broad shade preceding the fine, dentate postmedial line which is almost vertical and very indistinct. In Nat. Museum from Guerrero, Mexico.
- povera*. **H. povera** Schs. (72 b). Closely allied to *H. coresia* Drc. ♂. Larger, the body and hindwing buffy brown. Forewing lighter brown; a darker line incurved from middle of costa to median vein, then inset and sinuous to inner margin; two dark lines at end of cell; postmedial line very fine and indistinct; a subterminal sinuous line of small darker spots. Avangarez, Costa Rica.
- salvadora*. **H. salvadora** sp. nov. (72 e). ♂. Body and wings saecardo's olive. Forewing: some blackish scales forming an oblique basal line on costa, and a fine postmedial line well outcurved beyond cell; two small black

streaks at end of cell, the cell itself darker shaded. Wings below rather paler. Expanse. 21 mm. Republic El Salvador.

H. jalisca *sp. nov.* (72 c). ♂. Body and wings pale wood brown. Forewing: a dark point at base; *jalisca*. some fuscous scales on discocellular; postmedial line indistinct, outcurved beyond cell, followed by a few faint clusters of darker scales; the end of cell somewhat paler. Expanse: 24 mm. Guadalajara, Mexico.

H. bipuncta *sp. n.* Draudt (72 c). ♂. Larger and more robust than the other species; body and *bipuncta*. forewings uniform clayey wood-brown; on forewings with 2 blackish spots in upper and lower angle of cell and a short blackish streak between 4 and 5 behind cell. Hindwings fuscous. Type: 1 ♂ from Guerrero (Mexico) in coll. DRAUDT.

4. Genus: **Animomyia** Dyar.

♂. Palpi porrect, slender, thinly scaled; proboscis absent. Antennae with long pectinations. Legs smooth, the hind tibiae with two pairs of spurs. Wings broad. Forewing: veins 2, 3, and 4 equally apart, 4 at lower angle; 5 above angle, but nearer to 4 than to vein 6; vein 6 from upper angle, 7, 8, 9 from end of areole which is large; 10 from areole, also 11, which anastomoses from cell with subcostal. Hindwing: veins 2, 3, 4 equally apart; 5 from middle of discocellular; 6 and 7 shortly stalked; at base 7 approaches 8, but is not connected with it by a bar.

This genus is doubtfully placed in the Liparidae by DYAR. Pearsall placed his genus Graefia in the Geometridae, and McDUNNOUGH agreed with him.

Type: *A. morta* Dyar.

A. morta Dyar. (72 c). ♂. Wings translucent, drab grey. Forewing: two slightly darker transverse *morta*. lines, the antemedial hardly traceable, the postmedial somewhat dentate from costa to cell, and with faint darker streaks on veins. Hindwing: a faint small spot at end of cell; traces of a fine postmedial line. Expanse: 18 mm. San Diego, California.

A. increscens Dyar (72 c). ♂. Larger than *morta* Dyar. Forewing: the terminal third mottled with *increscens*. clusters of darker striae so it is less transparent than *morta*; a distinct small spot at end of cell; postmedial line broad, well defined, evenly curved beyond cell. Hindwing: darker striae on terminal half; a faint medial line crossing discocellular which is slightly darker. Expanse: 20 mm. Laguna Beach, California.

A. smithii Pearsall. (72 c). ♂. Body and wings drab grey. Forewing thickly irrorated with drab *smithii*. points and striae; the two lines well defined, the antemedial outbent to median vein, then vertical to inner margin, the postmedial very slightly outcurved from vein 6 to vein 2 with darker streaks on veins; a dark point at end of cell. Hindwing light drab, the costal area somewhat paler. Expanse: 19—29 mm. Walter's Station, California.

5. Genus: **Eloria** Wkr.

♂. Palpi obliquely upturned; proboscis absent, slight, in some species present in the female only. Antennae with long branches, bipectinate, and tipped with bristles. Body slender; legs slender, smooth; fore tibiae with a long process, terminating in a curved joint; hind tibiae with a single pair of spurs. Wings broad, geometriform. Forewing: vein 2 further from 3 than 3 from 4; 4 from lower angle; 5 above angle; 6 from below upper angle; areole variable; 7, 8 and 9, 10 from areole, or 7 stalked with 8 and 9; 11 from cell. Hindwing: veins 2 and 3 apart well before angle; 4 from lower angle; 5 above angle; 6 and 7 stalked; 7 approximates 8, but there is no connecting bar. KIRBY makes *spectra* Hbn. the type of genus.

I. Forewing with veins 7—10 stalked.

E. mallalia *sp. nov.* (73 a). ♂. Antennae with the pectinations tiller buff. Frons white, vertex and collar *mallalia*. orange yellow. Thorax and abdomen white, the latter with a black dorsal line. Wings white, all the veins drab. Forewing with basal third of costa narrowly fuscous. Expanse: 38 mm. Mallali, British Guiana. Genitalia.

Harp symmetrical, slender, tapering, but very faintly scobinate toward apices; apices hooked; viewed ventrally and unspread harpes no longer than tegumen to base of uncus; uncus deeply bifurcate, rather long; anellus a semichitinous simple tubular support fusing with the strongly arched transtilla; aedoagus very stout (about half as broad as long), straight apex strongly chitinized and produced into a short stout right angular hook; cornuti a dense cluster of heavy spines. (Slide made and described by C. HEINRICH.)

captiosa. **E. captiosa** *sp. n.* Draudt (73 a) belongs to the same group; Antennae drab, head and collar yellowish-white, body white, abdomen with light buff dorsal stripe. Wings thinly scaled, white, veins and discocellulars drab on both wings. Underneath apex of forewings suffused with drab. Type one ♂ from Rio Songo e coll STGR. in Mus. Berlin.

II. Forewing with veins 7, 8, and 9 stalked.

festiva. **E. festiva** *Wkr.* (nec *Cr.*) (73 a). ♂. Antennae with the shaft white spotted with fuscous, the pectinations drab. Frons white, vertex and collar yellowish. Thorax and abdomen white, the latter with a fuscous dorsal line. Wings white, the veins fuscous except the discocellular of hindwing. Forewing with the areole long and narrow. Rio de Janeiro, Brazil.

compulsa. **E. compulsa** *sp. n.* Draudt (73 a). Very near to *festiva*, smaller, apex of forewings more acute, more thinly scaled; antennae paler, pectinations nearly white; veins and discocellulars on both wings more heavily fuscous. May be only a more northern form of *festiva*. Type: 1 ♂ from Arouary (Cayenne), in Mus. Berlin (SAHLKE coll.).

ebba. **E. ebba** *sp. nov.* ♂. Pectinations of antennae light drab. Wings white, the veins and discocellular drab. It differs from *mallalia* Schs. in venation from areole and in genitalia. Expanse: 40 mm. Venezuela, Amazons. ♂ genitalia as in *mallalia* Schs. except harpes longer, reaching almost, if not quite, to end of uncus; aedoeagus with apex strongly chitinized and tapering to a curved point, but very slightly hooked; cornuti a single comb of very short spines. (C. HEINRICH *).

corvicoa. **E. corvicoa** *sp. nov.* ♂. Head, collar and body creamy buff, the dorsal line on abdomen very faint. Wings white, the veins very faintly vinaceous buff; a paratype from Venezuela is only distinguishable from *ebba* Schs. by the genitalia. Veins 7—9 on a longer stalk. Type from Corvico, Bolivia. ♂ genitalia with harpes symmetrical, elongate, slender, curved, tapering, strongly scobined on apical half; uncus rather long, very slightly bifurcate (with scarcely more than a triangular invagination) at apex; anellus produced beneath into a deeply bilobed heart shaped plate, fusing above into the divided arms of the transtilla; aedoeagus moderately stout; apex bluntly pointed, rather strongly chitinized with a short sharp sub-apical lateral spur; cornuti a comb-like cluster of moderately short, stout spines. (C. HEINRICH.)

limata. **E. limata** *sp. n.* Draudt (73 b). ♀. Head and collar creamy white, body otherwise white; abdomen with black dorsal stripe except last three segments. Wings with apices very rounded, white, very thinly scaled, costa somewhat more heavily scaled; veins light buff. Underneath some very light buff suffusion on costa and apex. Type: 1 ♀ from Chaco (La Paz), Bolivia, e coll. STGR. in Mus. Berlin.

subnuda. **E. subnuda** *Wkr.* (73 b). ♂. Shaft of antennae white, the branches drab. Body white, the vertex and collar yellow. Wings semihyaline, white, the veins white; costal margin broadly, termen and inner margin more densely scaled; costa of forewing finely black, more defined on under side. Honduras; Mexico. This is the *festiva* of the Biologia (nec *Hön.*).

edana. **E. edana** *sp. nov.* ♂. Shaft of antennae cream colour with drab branches. Head and thorax white. Abdomen cream colour with fine white segmental lines; a very faint dorsal line. Wings white, the veins light buff. Forewing below with the costa and apex light buff. Expanse: 33 mm. Venezuela. Small proboscis in ♂.

noyesi. **E. noyesi** *sp. nov.* (73 b). ♀. Antennae with shaft white, the pectinations drab. Head and body white, the abdomen with a dorsal buff line. Wings white, semihyaline iridescent; veins finely light drab. Forewing: the costal margin suffused with light drab, the apex rather broadly light drab narrowing to tornus. Hindwing below with termen narrowly light drab. Showing in transparency on upper surface. Expanse: 38 mm. Venezuela. Named for Mr. NOYES, the artist who is doing such beautiful work.

*) Seems rather variable; specimens occur with the discocellulars on both wings very broadly suffused with fuscous; such are before me from Sao Paulo de Olivença (Amazons); in specimens in the U. S. Mus. the genitalia are the same as *nugax*. in *ebba*; we are figuring it as — **nugax** *form. n.* Draudt (73 a). — Other specimens which are before me from Sarayacu (Ecuador), have head and collar white, not yellow, on hindwing veins 4 and 5 are wider apart; as communicated by SCHAUS. the same form is under *ebba* in the U. S. Mus.; genitalia not examined; perhaps a good species: **albicollis** *f. n.* Draudt (73 a). Types of both names in Mus. Berlin (DRAUDT).

E. schausi *sp. n.* Draudt (73 b). Very similar to the preceding species, wings more semihyaline and *schausi*, somewhat iridescent, all the veins drab; discocellulars on forewing very broadly suffused with drab. Forewing: subeostal area dull white, only veins and interspace between 11 and 7 suffused with fuscous; apex fuscous, similar to *noyesi*, terminating in a point at tornus. Termen of hindwings at vein 4 somewhat produced to a slight angle, more broadly suffused with drab. Type: 1 ♂ from Amazonas e coll. STGR. in Mus. Berlin.

E. lucida *Wkr.* (73 e). ♂. Antennae black. Head and collar orange. Thorax light neutral grey. *lucida*. Abdomen white mottled above with drab; dorsal and lateral fuscous lines. Wings white, thinly scaled, the veins fuscous. Forewing: apex suffused with mouse grey, more heavily marked on underside, where the costa is similarly suffused. Hindwing below with some terminal dark irrorations; cilia dark tipped with white. Brazil.

E. hiulca *sp. n.* Draudt (73 e). ♂. Shaft of antennae fuscous, pectinations drab. Head and collar *hiulca*, yellow; thorax and abdomen white, no dorsal stripe. Wings semihyaline white, veins in terminal third broadly suffused with drab, also subeostal area and apex; very broadly so the discocellulars on forewing and veins 3 and 4, the latter connected with discocellulars; on hindwing base of cilia drab. Type: 1 ♂ from Columbia in Mus. Berlin e coll. STGR.

E. discalis *Wkr.* (= *eryeinoides* *Fldr.*) (73 e). ♂. Body and wings fuscous black; abdomen below *discalis*, white. Forewing: basal third more thinly scaled, hair brown; white streaks in cell; a white patch between veins 2 and 3, terminating in a point near termen; 3 subapical white spots between veins 7—4, and a point below vein 4. Hindwing with interspaces thinly scaled, white at termen. Amazons.

E. chorax *Drc.* evidently closely allied to *discalis* *Wkr.*, has the black very much reduced. Sarayacu *chorax*, Ecuador.

E. chares *Drc.* is larger with a large orange yellow spot from costa before apex to tornus. I have not *charcs*, seen specimens of these two species, and do not know whether they belong to this group or the following with veins 7 not stalked with 8. Sarayacu Ecuador.

III. Vein 7 on forewing not stalked.

E. intacta *Wkr.* (73 c). ♂. Antennae: shaft white with small drab spots; branches light drab. Head *intacta*, and body white; collar yellowish; abdomen with a light drab dorsal line. Wings semihyaline white, the veins finely light drab. Underneath the termen narrowly drab; the costa of fore wing with slight light drab suffusion. Pará.

E. insulsa *sp. n.* Draudt (73 e). ♂. Very similar to *intacta*, whole body white, collar not yellow, *insulsa*, abdomen with fuscous dorsal line. Wings semihyaline white, veins very finely fuscous black, discocellulars on hindwing white, not drab. Underneath only the apex of forewings somewhat suffused with drab. 1 ♂ from Corvico, Bolivia, Type in Mus. Berlin.

E. manesia *sp. nov.* (73 e). ♂. Similar to *intacta* *Wkr.*, the discocellulars on both wings more heavily *manesia*, marked with drab. Wings below with tips of veins drab; no drab suffusion at apex of forewing. Expanse: 38 mm. Amazons. ♂ genitalia as in *E. mallalia* except: harpes asymmetrical, left shorter than the right terminating in a ragged strongly scobinate, irregularly shaped but unhooked apex; apex of right harp hooked and strongly scobinate. Cornuti as in *E. ebba*. (C. HEINRICH.)

E. venosa *Wkr.* (73 d). The largest of the white, dark veined species. ♀ from Colombia differs from *venosa*, the figure of the ♂. Lep. Het. in B. M. Vol. 5, pl. 89, fig. 1, in having the veins on hindwing white. It is possible our specimens represent a different species. Proboscis present in ♀.

E. jocosa *Dogn.* (73 d). ♂. Head hair brown; shaft of antennae white, branches fuscous. Thorax *jocosa*, and abdomen white, the latter with dorsal hair brown fuscous. Wings white, the veins finely hair brown, the discocellulars white; costal margin of forewing broadly hair brown. Expanse: 32 mm. Type from Manaos, Amaz.; also from Villavieeneio, Colombia.

E. onaba *Drc.* (73 d). ♂. Differs from *E. jocosa* *Dogn.* in being frequently larger, the veins hair brown *onaba*, on terminal third of wing, and more heavily marked. The ♀ usually has the apex of forewing suffused with hair brown. Expanse: ♀ 40 mm. Costa Rica; Panama.

- pellucida*. **E. pellucida** Hbn. (= *turbida* Wkr.) (73 d). ♂. Wings white, semihyaline iridescent, the veins black. Forewing: costal margin black widening before apex which is broadly black, narrowing to tornus; a black spot on discocellular. Hindwing with termen broadly black. I only know the type of *E. turbida*, which has vein 7 not stalked with 8.
- moconia*. **E. moconia** Drc. (73 d). ♂. Palpi, head and thorax orange yellow. Abdomen white with a dorsal hair brown line and irrorations. Wings dull white, the veins well defined, drab with similar suffusions terminally; a yellow spot at base of forewing. Described from Guiana; Southern Brazil. Small proboscis in both sexes.
- remota*. **E. remota** Wkr. (73 d). ♂. Shaft of antennae white, the branches drab darkest at base. Body white, the anal hairs light buff; traces of a buff dorsal line. Wings white, very thinly sealed, iridescent; the costa of forewing finely light buff. Expanse: ♂ 38 mm. Colombia.
- spectra*. **E. spectra** Hbn. (73 e). ♂. Shaft of antennae white, the branches light buff. Head and body white. Wings white, the veins more heavily scaled. Forewing below with the costa and apex suffused with vinaceous buff. I am not sure that this is correctly identified. HUBNER's figure of the ♂ shows a cluster of dark scales at the base of forewing. Venezuela; the Guianas; Trinidad.
- cubana*. **E. cubana** Schs. ♂. Shaft of antennae white, the branches light buff. Wings white, thinly sealed, the termen of forewing somewhat oblique. Wings below pure white. Baracoa, Cuba.
- diaphana*. **E. diaphana** Stoll. Unknown to me. The figure represents a white species; wings with veins finely dark, the costal edge distinctly black. Allied to *intacta* Wkr. and *mallalia* Schs. Expanse: 40 mm. Surinam.
- gigantea*. **E. gigantea** Drc. (73 e). ♂. Body white in fresh specimens, usually discoloured in collections. Wings white, the apex of forewing below slightly suffused with light drab. Expanse: ♂ 39 mm, ♀ 50 mm. Central America to the Guianas.
- aroensis*. **E. aroensis** Schs. ♂. Body and wings white, the forewing showing slightly the broad apical light cinnamon drab suffusion of underside. Expanse: 37 mm. Aroa, Venezuela.
- serena*. **E. serena** Schs. (73 e). ♂. Head and collar pale yellow. Body and wings creamy white; costal edge of forewing black, the underside purer white, the costa and apex fuscous. Expanse: ♂ 37 mm; ♀ 57 mm.
- sixola*. **E. sixola** Schs. (73 e). ♂. Head and collar yellow. Body white, thinly scaled. Forewing: the costa finely fuscous; underside as above, the apex broadly, the termen narrowly at tornus fuscous, faintly visible in transparency on upper side. Expanse: ♂ 44—46 mm. Costa Rica.
- torrida*. **E. torrida** Schs. (73 e). ♂. Body creamy white. Wings white thinly sealed. Forewing: costa finely fuscous; apex to vein 4 narrowly drab; underneath the costa more broadly fuscous. Expanse: ♂ 32 mm; ♀ 42 mm. Costa Rica.
- subapicalis*. **E. subapicalis** Wkr. (73 f). ♂. Similar to *E. torrida*. Forewing: costa finely black at base; at apex the darker scaling of underside, only shows in transparency. Venezuela; Mexico.
- marginalis*. **E. marginalis** Wkr. (73 f). Larger than *discifera* Wkr. Expanse: 37—43 mm. Head yellow buff. Wings white, the margins darker, on inner margin of forewing reduced to a line on submedian. The Guianas; Amazonas.
- nigella*. **E. nigella** Dogn. (73 f). Head orange yellow. Wings cream white, the margins fuscous, broader than in *E. marginalis*. Amazons.
- moeschleri*. **E. moeschleri** Dogn. (73 f). ♂. Head and palpi brown. Wings creamy white, the fuscous margins still broader than in *E. nigella* Dogn. The abdomen suffused with drab. Amazons.
- ninya*. **E. ninya** Dogn. (73 f). ♂. Head vinaceous fawn. Abdomen above hair brown. Wings white with very broad hair brown margins, the forewing with the white portion reduced to an elongate triangular spot. Amazons.
- nimbosa*. **E. nimbosa** Dogn. (73 f). ♂. Head and collar orange. Wings as in *E. ninya* Dogn., but the central creamy white portions still more reduced. Amazons.
- flavicollis*. **E. flavicollis** Dogn. (73 g). ♂. Collar yellow. Body above hair brown, underneath whitish. Forewing thinly scaled at base and along inner margin, irrorated with hair brown; a large cream white patch from subcostal at middle, across cell to near termen; apex broadly fuscous more thickly scaled. Hindwing semihyaline irrorated with hair brown, the veins darker. Forewing below greyish white from base to dark apical area. Expanse 32 mm. Rio Tapajos, Amazons.

E. albifasciata Dogn. (73 g). ♂. Smaller than *flavicollis* Dogn. Collar concolorous with thorax, hair *albifasciata*. brown; the postmedial patch crossing end of cell, white, its outer edge curved. Forewing below as on upper surface. Expanse: 28 mm. Amazons.

E. moesta Wkr. (73 g). ♂. Wings almost entirely dusky drab with a small pale patch at lower end of *moesta*. cell and base of veins 3 and 4. Wings underneath yellowish glaucous, all the margins broadly brownish black. Amazons.

E. ombrea Drc. (73 g). ♂ described as dusky brown, rather paler from base to about middle. The species *ombrea*. is unknown to me. Fig. in Biologia t. 15, f. 8. Costa Rica.

E. cissusa Drc. (73 g). ♀. Head and collar yellowish brown. Abdomen fuscous above, yellowish brown *cissusa*. underneath. Wings whitish, the margins very broadly benzo brown. Forewing: the white portion elongated, narrow at base expanding and curved beyond cell, its basal half irrorated with dark scales especially on median vein. The ♂ is figured by DRUCE with only a large white spot beyond the cell, the hindwing with a cream coloured streak from base below costa to outer margin. Ecuador; Peru.

E. clodia Drc. (73 g). ♂. Head and collar bright yellow. Body black; abdomen below yellow. Wings *clodia*. semihyaline black. Forewing with a large round cream coloured spot about center of wing. Hindwing with some cream coloured scales at end of cell. Expanse: 38 mm. Santarem, Amazons. This species is unknown to me.

E. grandis Drc. (73 h). ♂. Antennae black. Frons light buff, vertex yellowish. Abdomen white in *grandis*. fresh specimens. Wings white; thinly scaled. Forewing: costa and apex broadly hair brown. Expanse: ♂ 40 mm, ♀ 74 mm (fide DRUCE). Amazons; Fr. Guiana; Colombia; Peru.

E. apicalis Wkr. (73 h). ♂. Head and collar yellow buff. Body and wings creamy white. Forewing: *apicalis*. costal edge black, the apex more broadly dark hair brown. Underside the same. Expanse: 38 mm. Amazons.

E. opaca Dogn. (73 h). ♂. Head and collar orange yellow. Body and wings creamy white. Forewing: *opaca*. costa narrowly, apex broadly hair brown. Underside the same. Expanse: 38 mm. British Guiana.

E. discifera Wkr. (73 h). ♂. Head yellowish. Body white with some greyish suffusions on thorax. *discifera*. Wings thinly scaled white. Forewings: the margins light drab, widest at apex. Hindwing: the termen narrowly light drab. Expanse: 34 mm. The Guianas and Amazons.

The following three species described under *Eloria* should be transferred to **Xenosoma** of the Pericopidae

E. velhoa Schs. (73 i). ♀. Palpi and frons whitish; vertex yellowish. Thorax and abdomen white. *velhoa*. Wings white semihyaline, the veins clearer white. Forewings: costa greyish brown; terminal space with smoky brown streaks on interspaces, the longest between veins 2 and 3, and 5 and 6; the shortest between veins 3 and 4, and above tornus. Rio Madeira, Amazons.

E. nicander Drc. ♂. Head and thorax orange yellow. Body white, anus orange yellow. Wings white, *nicander*. the veins faintly drab; costal edge black; mouse grey suffusions at apex, more intense and broader in the ♀ where they extend along termen. Costa Rica; Panama.

E. geometrina Schs. (73 h). ♂. Head, collar, and anal tufts orange, body otherwise light mouse grey, *geometrina*. with paler segmental lines. Wings semihyaline white, the margins broadly greyish drab. Forewing with the median vein, base of veins at cell, and an oblique broad shade from end of cell to inner margin before tornus light drab. Costa Rica.

6. Genus: **Caviria** Wkr.

Palpi upturned, slender, clothed with hairs. Antennae bipectinated to tips. Proboscis aborted. Legs including tarsi hairy; hind tibiae with terminal pair of spurs. Forewing broad, costal margin arched towards apex; termen slightly rounded; veins 2, 3, 4 equally apart; vein 5 above angle; 6 from upper angle; areole variable, vein 7 from near end of areole; 8 and 9 on long stalk from areole; 10 from close to end of areole;

11 connected with subcostal by a bar, or anastomosing with 10 to form the areole, rarely free. Hindwing broad; inner margin longer than costal margin, the termen almost straight in ♂, rounded in ♀; veins 3, 4, 5 equally apart; upper half of discocellular very faint, 6 and 7 stalked.

Type: *comes* Geyer.

- regina*. **C. regina** Cr. (74 a). ♂. Antennae with shaft white, the branches light ochraceous buff; palpi benzo brown fringed with white hairs; fore tibiae streaked with black. Body white. Forewings silver white with duller silver markings; streaks in cell; antemedial line narrow from cell to inner margin; postmedial broad from costa near apex to middle of inner margin, followed by a fine line; a subterminal narrower line from termen below apex parallel with postmedial, incurved below vein 2; marginal irregular markings; costal edge sometimes fuscous. Hindwing silvery white. Expanse: ♂ 44 mm; ♀ 58 mm. The Guianas; Amazons; Central America.
- doda*. **C. doda** sp. nov. (74 a). ♂. Very similar to *C. regina* Cr., smaller, the lines more undulating, narrower. Forewing: the subterminal not incurved below vein 2; the costal edge finely brown. Expanse: ♂ 30 mm; ♀ 45 mm. The Guianas; Amazons; In this species vein 11 is free.
- sericea*. **C. sericea** Fldr. (74 a). ♂. Forewing: differs from the previous species by the more obliquely inbent lines which are still narrower; postmedial line from apex; the subterminal line fine and gently incurved. Hindwing with anal angle more produced. Amazons.
- micans*. **C. micans** Wkr. (74 a). ♀. Shaft of antennae yellow ocher irrorated with fuscous; fore and hind legs orange with black spots; body white. Wings silvery white without the brilliant shading of the other species. Forewing: costa and cilia yellow ocher. The only known species with yellow cilia. Amazons.
- andeola*. **C. andeola** sp. nov. (74 b). ♂. Antennae with shaft white, the branches buff white; palpi, throat and fore femora fuscous black. Wings thinly scaled, silvery white, the duller markings forming double postmedial and subterminal lines. The only species with fuscous palpi. Expanse: 36 mm. Nova Friburgo, Brazil.
- hedda*. **C. hedda** sp. nov. (74 b). ♀. Antennae as in *C. andeola*. Palpi, throat and fore femora white. Body white. Forewing silvery white, the duller silver lines very wavy; antemedial line deeply incurved; postmedial and subterminal lines narrow, double, and another line closer to margin. Hindwing creamy white, thinly scaled except on veins. Expanse: 45 mm. Rio de Janeiro.
- vinasia*. **C. vinasia** sp. nov. (74 b). ♂. Branches of antennae drab; palpi, throat and body white. Forewing silvery white, the lines less wavy than in *C. hedda*. Hindwing white, thinly scaled. Expanse: 33 mm. Juan Viñas, Costa Rica.
- vestalis*. **C. vestalis** Schs. (74 b). ♂. Antennae with shaft white, the branches light buff; palpi white streaked with fuscous above. Body white. Wings duller white irrorated with slightly silvery scales, the duller portion forming indistinct antemedial, postmedial, and subterminal lines. Expanse: 30 mm. French Guiana.
- comes*. **C. comes** Gey. (= *substrigosa* Wkr.). ♂. Branches of antennae light buff. Palpi white streaked above with brown. Body white. Forewings silvery white, the duller lines narrow, slightly wavy, double, appearing more numerous. Hindwings broad, considerably longer on inner margin than on costal, dull white, somewhat hyaline. Expanse: ♂ 30 mm; ♀ 42 mm. Southern Brazil.
- odriana*. **C. odriana** sp. nov. (74 c). ♂. Belongs to the group of *C. comes* Gey., the lines very numerous. Palpi white, faintly light buff above. Body white. Forewings silvery white, the lines slightly wavy, the duller silver lines very narrow; costal edge finely fuscous; the apex acute. Hindwing semihyaline, the veins more heavily scaled. Expanse: 37 mm. La Oroya, Peru.
- marcellina*. **C. marcellina** sp. nov. (74 c). ♀. Palpi light buff fringed with white hairs. Body white. Forewings with the silvery white lines numerous; postmedial line outbent from costa, angled and inbent to middle of inner margin; subterminal line outbent on costa and parallel with postmedial, followed by another finer line. Hindwings semihyaline, dull white. Expanse: 38 mm. São Paulo de Olivença, Amazons.
- athana*. **C. athana** sp. nov. (74 c). ♂. Antennae with the shaft white, the branches wood brown. Palpi and body white. Forewings silvery white, the duller lines narrow, the postmedial curved below costa; the costal edge wood brown, also the tips of cilia from vein 5 to apex, more apparent on underside. Hindwing semihyaline white, the veins silvery white. Expanse: 27 mm. São Paulo de Olivença, Amazons.

7. Genus: **Olene** Hbn.

♂. Antennae deeply bipectinate, the branches with terminal bristles. Palpi upturned, densely scaled. Abdomen with dorsal crests. Legs hairy including tarsi; hind tibiae with two pairs of spurs. Fore wing in type species broad or frequently narrow; vein 2 well before angle of cell; 3 near angle; 4 from angle, 5 slightly above; vein 6 from upper angle; areole present; veins 7, 8, 10 from areole, 9 on long stalk with 8; vein 11 free running closely along subcostal, sometimes suffusing shortly with it. (This occurs in *mendosa* occasionally). Hindwing: vein 2 well before angle; 3 and 4 slightly apart or from angle; 5 slightly above angle; 6 and 7 on short stalk.

Type: *O. mendosa* Hbn.

O. basiflava Pack. (= *clintoni* G. & R.) (72, c, d). ♂. Forewing grey mottled with brown and drab; *basiflava*. antemedial line fine black, faintly wavy dentate above cell; medial space from costa to median vein whitish with dark irrorations; postmedial line slightly outcurved, black, fine wavy; terminal space with brown mottlings irregularly defined. Hindwings brown; a fuscous discal spot and traces of a postmedial dark line. ♀. Base of forewing yellowish brown with chestnut brown markings; antemedial line outbent, incurved below cell; medial space with whitish anterior space as in male, from cell to inner margin more mouse grey; postmedial line followed by a broad chestnut brown shade on interspaces; a pale wavy subterminal line. North Atlantic States. — f. **meridionalis** B. & McD. (72 d) has the ♂ smaller, the base darker, the medial space below cell *meridionalis*. greyer; the ♀ has a white-grey abdomen, the dorsal tufts chestnut brown very distinct; the entire medial space whitish crossed by a faint darker grey shade; antemedial line consisting of a narrow brown shade; a fine black line on discocellular; termen irregularly whitish grey; a black terminal line, very irregular towards tornus. Florida.

O. kervillei B. & McD. (72 c). ♂. Body light drab, the dorsal tufts on abdomen black. Forewing: *kervillei*. basal and terminal areas light cinnamon drab, the medial space greyer; lines black, the antemedial forming several curves, the postmedial vertical from costa to vein 5 then sinuous. Hindwing light cinnamon drab. Kerrville, Texas.

O. vagans B. & McD. (72 d). ♂. Head and collar drab grey; thorax and abdomen hair brown. Fore- *vagans*. wing drab grey tinged with olive; antemedial line vertical somewhat sinuous; medial space greyer; discal space whitish with a large reniform finely outlined in black; postmedial line outcurved beyond cell, incurved in submedial space; postmedial followed from vein 4 to costa by a broad olivaceous brown space, limited by the pale irregular subterminal shade. Hindwing drab with faint dark discal spot, and a dark subterminal line. ♀. Forewing: the brown basal space with darker suffusions and limited by the wavy antemedial fuscous line; medial space whitish with dark irrorations on costal half, the reniform outlined in black; medial space below cell neutral grey; postmedial line fine, black, wavy, followed by a broad benzo brown shade, narrowing towards inner margin, and limited by an irregular subterminal whitish shade. North Eastern States; Canada. — subsp. **grisea** B. & McD. (72 e). ♂ and ♀ greyer with some light drab suffusions, the basal areas with dark suffusions; *grisea*. antemedial an irregular narrow shade; reniform incurved, outlined by a black line; postmedial vertical from costa in ♂, incurved in ♀ where it is followed by a greyish brown shade, limited by the whitish subterminal shade. Hindwings drab in ♂, paler in ♀; a dark discal spot and postmedial darker line. Utah. — subsp. **willingi** B. & McD. (72 e). ♂. Much darker than two preceding forms, of a general suffused blue black appearance. *willingi*. Forewing: antemedial line broad, wavy; postmedial finer, followed by a broad dark shade; medial space paler especially around reniform, below cell colour variable; subterminal whitish indistinct. Hindwing hair brown. Humboldt, Sask., Canada.

O. atrivenosa Palm. (72 e). ♂. Forewing greyish fuscous, the veins with blackish brown scales; inner *atrivenosa*. half of wing paler with several irregular whitish patches; postmedial line black, somewhat curved, and inangled above submedian, followed by a dark shade, its outer edge irregular, narrower below vein 4; subterminal shade greyish, diffuse. Hindwing greyish fuscous with dark discal spot; termen broadly paler. This species is only known to me by description of Barnes and McDUNNOUGH and figure from photograph of type. Arkansas.

- leucophaea*. **O. leucophaea** A. & S. (72 e). ♂. Forewing purplish grey; a short basal line, and basal space towards inner margin suffused with brown; antemedial line vertical, sinuous; medial space from costa to median vein paler; reniform large, oblique partly outlined in black; postmedial line outbent on costa, outcurved between veins 5 and 3, incurved and bent outwards above inner margin, followed by a brown shade and traces of suffused dark longitudinal streaks most prominent near costa. Hindwing dark smoky brown. ♀ paler; antemedial line inangled at median; medial space neutral grey on inner half, costal half whiter; reniform faint; postmedial line wavy, inbent on costa; subterminal dark line outangled between veins 6 and 7, outcurved above vein 3 preceded by brown suffused with dark streaks. Hindwing pale smoky with darker subterminal shade and discal spot. Georgia.
- dorsipennata*. **O. dorsipennata** B. & McD. (72 f). ♂. Forewing olivaceous grey; basal line black, short; antemedial line double, lunular; reniform broad, incompletely outlined in black, surrounded with whitish, less so than in other species of group; postmedial line irregularly dentate, strongly inangled above inner margin, followed by a diffuse drab shade; subterminal shade whitish, irregular with whitish patch near tornus; a fine marginal black line. Hindwing smoky brown with diffuse lines. ♀ very similar to ♂; discal patch whiter, larger; marginal black line inwardly edged with white. Chelsea, Quebec, Canada.
- atomaria*. **O. atomaria** Wkr. (= *obliquata* G. & R.) (72 f). ♂. Forewing: basal area mostly wood brown limited by the fine dark antemedial line which forms three outward curves; a short basal line; medial space whitish around reniform; postmedial line wavyly outcurved, incurved above submedian; subterminal whitish shade indistinct. Hindwing dark smoky brown; traces of discal spot and subterminal line. ♀ paler; antemedial line more angular; postmedial line more vertical wavy. Eastern States. — f. **parallela** G. & R. (72 f). ♂ very similar to *O. atomaria* Walk. Forewing: base and suffusions beyond postmedial of a deeper brown; a black streak from base below cell to postmedial or beyond. ♀ with dark scaling on median; an almost medial brown shade outbent from costa, then inbent from within cell to the dark streak in submedian space; the brown shading beyond postmedial more pronounced than in *O. atomaria* Wkr. New England; Pennsylvania. — f. **aridensis** Benj. (72 g). Size, lines and ordinary spots as in *O. atomaria* Wkr. ♀. Forewing: basal area and subterminal area chocolate-brown; medial space pale, olivaceous with tendencies to bluish or greenish; reniform strongly outlined by a dark line and filled in with whitish. Hindwing medium brown, with darker discal spot and outer line. New Jersey. Said to be a form of *O. atomaria* Wkr.
- achatina*. **O. achatina** A. & S. (72 d). This species has never been properly identified according to BARNES and McDUNNOUGH chiefly because the larva has not been identified and bred. In the Insects of Georgia, the figures represent a large species with a pronounced broad fuscous dash in basal area below cell. ♂. Forewing: basal and terminal areas wood brown, the latter with a series of fuscous dashes on interspaces beyond postmedial; the medial area is bluish white with dark irrorations, the reniform outlined by black lines. ♀. Forewing: basal area like medial bluish white space; antemedial line wavyly curved, dark brown preceded by a white line; the dark spots beyond postmedial larger, followed by a whitish subterminal shade. Georgia. We are figuring a ♀ from the Berlin-Museum with the label „Georgia“ which seems to match the description and shows clearly the dash in basal area below the cell, absent in the very similar *O. meridionalis*.
- cinnamomea*. **O. cinnamomea** G. & R. (72 g). ♂. very similar to *O. atomaria* Wkō, but browner on basal and terminal areas. Forewing entirely brown; lines brown shaded on either side with whitish scales; medial space with whitish scales on costal half, on which a brown reniform ringlet indicates the discal spot; a dark greyish patch medially above inner margin; postmedial line outbent at vein 2, incurved above submedian; some greyish scales on termen. New England States; New York.
- manto*. **O. manto** Streck. (72 g). ♂. Forewing chestnut brown; a faint basal lunular line; antemedial black line lunular dentate, vertical; postmedial black, irregular, curved inwardly between veins 3 and 4; reniform large outlined in white, the costa above between the lines white irrorated with black; some white scales on inner margin between the lines; a sinuous whitish subterminal shade. Hindwing dark greyish brown with traces of darker discal spot and subterminal shade. ♀ very similar to the male; discal area whiter; the subterminal white shade more irregular. Georgia. — f. **interposita** Dyar. (72 h). ♂ smaller, more uniformly brown. Forewing: the lines black, distinct, irregularly crenulate; a white cloud in the discal area defining the brown filled, oblique

reniform; subterminal line pale, followed by a greyer terminal area. In the ♀ the medial space is largely grey. Tryon, North Carolina.

O. montana *Beut.* ♂ dark smoky brown with a slight violaceous lustre; transverse lines and discal spot *montana*, almost obscured, the latter with a few white scales; antemedial line forming three curves; postmedial line outcurved around discal spot, inbent above middle, then nearly straight to inner margin; a white spot above tornus; terminal black line dentate at tornus. ♀ deep sepia brown; lines distinct; discal mark filled with clear white; white spot at tornus larger. Expanse: ♂ 32 mm, ♀ 36 mm. Summit of Black Mountains, North Carolina.

O. pini *Dyar* (72 h). ♂. Forewing grey, irrorated with black; some brown shading in basal and medial *pini* areas; a small black basal line; antemedial and postmedial lines black, distinct, crenulate, the latter inangled at submedian; discal space whitish, reniform open, broken into two black bars with white edgings; subterminal line whitish, wavy with white spot above tornus; marginal line black, crenulate. Massachusetts; New York.

O. plagiata *Wkr.* (= *pinicola Dyar*) (72 h). ♂. Forewing cinereous fawn colour irrorated finely *plagiata* with black; a black basal line, outbent at inner margin; antemedial line dentate below costa, outbent below cell, inangled on submedian; postmedial line wavyly dentate, outcurved around cell; subterminal line whitish, inwardly dark edged towards costa with a well marked white spot above submedian; a black marginal line; reniform black lines on a whitish space. ♀ very similar to the ♂, the black marginal line partly edged inwardly with white. Wisconsin; Canada.

O. styx *B. & McD.* Forewing fuscous, all traces of maculation practically lost with the exception of *styx*, an obscure black basal dash, a large reniform very faintly outlined in whitish and a small white spot above tornus. Hindwing deep smoky in the ♀ with outer margin concave below apex, in the ♂ well rounded. Considered probably a melanic form of *O. plagiata Wkr.*, as *O. montana Beut.* is of *O. manto Streck.* Duncans, British Columbia,

O. grisefacta *Dyar* (72 h). ♂ and ♀. Forewing whitish coarsely irrorated with drab; lines broad, *grisefacta*, black, the antemedial wavyly dentate, the postmedial wavy, outcurved around cell, incurved below cell to submedian; discal mark broad, whitish, reniform black outlined, broken above; subterminal diffuse, indistinct with whiter spot above tornus; a marginal black line, crenulate, receding somewhat from termen. Colorado.

O. bonniwelli *B. & Benj.* (72 h). ♂. Forewing pale grey tinged with brownish, and heavily dusted *bonniwelli* with black; lines black, the basal line outbent, the antemedial broad somewhat waved, slightly oblique, the postmedial well outcurved around cell, incurved below vein 4; a black dash at base below cell; reniform large outlined by black with brownish center, the whole somewhat surrounded by pale grey; subterminal a diffuse shade, outbent from costa to below vein 7, then inwardly oblique, obsolescent below vein 3, preceded above submedian by a black spot. Hindwing drab to dark brown. New Mexico.

8. Genus: **Stilpnotia** *Westw. & Humph.*

♂. Antennae bipectinated with terminal bristles. Palpi obliquely upturned, reaching vertex, fringed with long hairs. Fore tarsi with long process at base; hind tibiae with one pair of spurs. Forewing: vein 2 long before 3; 3 well before angle; 4 from angle; 5 above angle; 6 from below upper angle; 7—9 stalked; 10 and 11 from cell. Hindwing: veins 2—5 as on forewing; 6 and 7 stalked.

Type: *S. salicis* *L.*

S. salicis *L.* Vol. II, p. 127 (20 d). Has been introduced into the New England States.

salicis.

9. Genus: **Phreata** *Wkr.*

♀. Antennae slender, minutely serrate and setulose. Palpi short, porrect. Legs slightly hairy; hind tibiae with one pair of short spurs. Forewing: vein 5 close to 4; 6 from upper angle; 7, 8, 9 on long stalk; 10 and 11 from cell. Hindwing: veins 3 and 4 on long stalk; 5 from lower angle; 6 and 7 from upper angle.

Type: *P. glaucoalba* Wkr.

glaucoalba.

P. glaucoalba Wkr. ♀. Body white partly tinged with pale green; fore legs striped with ochraceous. Forewing creamy white. Hindwing thinly scaled, white. Bolivia. Have examined the type in British Museum.

10. Genus: **Thagona** Möschl.

♂. Antennae bipectinated with terminal bristles. Palpi upturned to frons, thickly scaled in front, the third joint somewhat porrect. Legs hairy, including the tarsi; hind tibiae with single pair of spurs. Wings broad; veins 2—4 well apart, 4 from lower angle of cell; 5 slightly above angle; 6 from upper angle; 7—10 atalked, 10 from 8 before 7; 11 free. Hindwings: vein 2 well before end of cell; 3, 4, 5 slightly apart; 6 and 7 from upper angle.

Type: *T. uniformis* Moeschl.

hedila.

T. hedila Drc. (72 k). ♂. Antennae light buff. Palpi, thorax and abdomen buck thorn brown; vertex and collar white. Forewing mostly yellow ocher crossed by Kaiser brown veins; base of wing broadly pure white; an irregular curved white crescent on end of cell, enclosing a yellow ocher space containing some black scales; apex white; termen below vein 5 white to tornus, more broadly between veins 5 and 3. Hindwing white suffused with light drab, becoming darker on termen. Expanse: ♂ 14—25 mm, ♀ 34 mm. Amazons; Peru; Costa Rica.

taus.

T. taus Dyar (72 k). ♂. Head, collar and thorax laterally white. Abdomen above drab with white segmental lines, underside and legs white. Forewings pinkish cinnamon; median beyond vein 2 and discocellular white, also base of veins from cell; costal margin medially white, its edge light buff; a fine dark streak in cell on basal half, followed by a broken white line; a broken white antemedial line, punctiform in cell, deeply incurved below cell; a dark medial spot above submedian; traces of a subterminal dentate white line; veins on termen tipped with white. Hindwing white. Expanse: 19 mm. Cayenne, French Guiana.

bilinea.

T. bilinea Schs. (72 i). ♂. Head and thorax drab grey. Abdomen above light ochraceous buff. Wings white. Forewing mottled with grey; the veins and two transverse thick lines and cilia isabella colour; inner line from middle of costa to near base of inner margin; outer line from costa near apex to middle of inner margin. Expanse: ♂ 37 mm; ♀ 56 mm. French Guiana; Amazons.

impura.

T. impura Schs. (72 h). ♀. Head, thorax and forewing light buff. Abdomen and hindwing white. Legs light buff with paired black lines on tibiae and tarsi. Forewing: veins faintly defined; two narrow transverse lines isabella colour; inner line from subcostal before middle to inner margin at one third from base. Expanse: 43 mm. São Paulo, Brazil.

postropaea.

T. postropaea Dyar (72 i). ♂. Head, thorax and forewing olive buff. Abdomen buff yellow when not discoloured. Hindwing white. Forewing: the veins broadly white except subcostal; two transverse isabella colour lines; inner line from middle of subcostal, which is also isabella colour from middle to base, inbent to submedian at one third from base; outer line from costa near apex to below middle of submedian and incurved to base. Expanse: ♂ 17 mm, ♀ 35 mm. The Guianas; Amazons.

crassilinea.

T. crassilinea Dogn. (= *bilinea* Dogn., *pura* Dogn.) (72 i). ♂. Shaft of antennae white, branches ochraceous buff. Head, thorax and legs white, palpi laterally black; mid tibiae and tarsi and hind tarsi thickly irrorated with black. Wings white, the veins more heavily scaled. Forewings: two rather broad light greyish olive lines cut by veins, the inner line from middle of costa to submedian at one fourth from base, the outer line from apex to middle of inner margin; at apex the scaling is black. Expanse: ♂ 36 mm, ♀ 49 mm. The ♀ has the anal segment above deep mouse grey. The Guianas; Amazons.

pura.

T. pura Wkr. (72 k). ♂. Body and wings white; branches of antennae buff; palpi above fuscous. Forewing crossed by two fine brownish lines; inner line from well beyond middle of costa to inner margin near base; outer line from interspace between veins 6 and 7 to near termen, then angled and inbent to inner margin before middle. Expanse: ♂ 28 mm, ♀ 35—40 mm. Amazons; Panama; Costa Rica.

unilinea.

T. unilinea Dogn. (72 k). ♂. Head and abdomen whitish; thorax and forewing light vinaceous cinnamon, the latter with an olivaceous brown line from apex to inner margin near base. Hindwing with vinaceous suffusions, chiefly on termen. ♀. Forewing pale pinkish buff irrorated with vinaceous buff; the line as in ♂. Expanse: ♂ 17 mm, ♀ 30 mm. Amazons; British Guiana.

limula.

T. limula Dogn. (72 i). ♂. Body and wings white. Palpi and abdomen laterally olivaceous; vertex with some vinaceous scaling. Forewing: lines below subcostal, in cell, below cell and below submedian and in

terminal interspaces pale olive brown; two similar transverse lines, the inner from subcostal beyond end of cell to submedian at one third from base, the outer line from near termen at vein 5 to middle of inner margin. São Paulo de Olivença, Amazons.

T. tarsalis Wkr. (72 k). ♂ white. Palpi with black tips. Antennae with testaceous branches. Legs *tarsalis*, with black bands, the forelegs testaceous. Wings with black points on cilia, two on forewing, three on hindwing; some black scaling at apex of forewing underneath. Para, Brazil; British Guiana.

T. uniformis Moesch. (= saphena Dyar). ♂ like *T. tarsalis* Wkr. Forelegs orange yellow in front with *uniformis*, black bands. No spots on cilia of wings. The Guianas.

T. parthenica Dyar. (= immaculata Dogn.). ♂. Entirely white. The interspaces on forewing more *parthenica*, silky. Differs from *T. uniformis* Moesch. in having the fore legs white, the branches of antennae paler. British Guiana; Amazons.

T. suppura Dyar. (73 i). ♂. Body and wings white; branches of antennae light ochraceous buff; *suppura*, tibiae and tarsi with some black scales. Forewing: fuscous black spots on cilia at interspaces. French Guiana.

T. punctifimbriata Dogn. ♂. Body and wings white. Shaft of antennae white at base then orange *punctifimbriata*, buff. Palpi fuscous black fringed with white hairs. Fore and mid legs orange buff with black transverse lines. Forewing: the costa narrowly black; black spots on cilia between veins 2 and 7. Expanse: 37 mm. Quindiu, Colombia. A ♀ in Nat. Mus. from Rio de Janeiro.

T. caramata Dogn. (73 i). ♂. Body white. Palpi black, the tips of fringe white. Forelegs streaked *caramata*, with black. Forewing silvery white, forming irregular more brilliant markings as in some species of Carama of the Megalopygidae, the costa below rather broadly snuff brown, but not reaching apex. Hindwing silvery white semihyaline. The ♀ has the costa below paler. Expanse: ♂ 42 mm, ♀ 47 mm. Loja, Ecuador.

T. medinata Dogn. (74 c). Wings proportionately narrower than in other species of genus. ♂. Antennae *medinata*, with white shaft, the branches mikado brown. Frons cream white, vertex white; palpi black; fore legs inwardly fuscous black; abdomen dorsally yellow with black segmental lines, almost entirely concealed by long white hairs. Forewing thinly scaled except on margins, buff white. Hindwing thinly scaled, white. Expanse: ♂ 29 mm, ♀ 39 mm. Medina, Colombia.

T. nivea Cr. Evidently belongs here, but is unknown to me. The figure represents a white species *nivea*, with dark terminal line and costa of forewing. The hindwing has three small subterminal brown spots at anal angle. Expanse: 63 mm. Surinam.

T. begga Cr. (74 c). ♀. Body and wings white. Palpi fuscous. Fore tibiae orange; fore tarsi black. *begga*, Forewing: costal margin fuscous black. Expanse: 48 mm. British Guiana; Colombia.

T. lojana sp. nov. ♂. Antennae pinkish buff. Body and wings white; a few black scales on fore *lojana*, legs. Forewing thinly scaled; a small rose coloured spot at base of subcostal; a small brown spot at lower end of cell, with a few brownish scales above it and beyond discocellular. Expanse: 31 mm. Loja, Ecuador.

T. tibialis Wkr. (73 i). ♂. Body white. Palpi black above with long white fringe. Legs white. Wings *tibialis*, dull white. Forewing: some fuscous or brown scaling on discocellular, usually forming two small spots; a similar small postmedial spot between veins 4 and 5. ♀ usually with two small spots on forewing, one at lower angle of cell, the other between veins 4 and 5, or both entirely obsolete. Expanse: ♂ 30 mm, ♀ 37—50 mm. Central America to South Brazil.

T. puntuada Dyar. ♀. Head vinaceous buff. Body white. Fore tibiae and tarsi with black scaling. *puntuada*, Forewing buff white; a fuscous line on basal side of discocellular and a curved spot on outer side; a small spot below vein 5 near cell. Underneath the costa is suffused with fuscous. Hindwing white rather thinly scaled. Loja, Ecuador.

T. persimilis sp. n. Draudt (74 d) agrees exactly with *puntuada*, but is pure white, instead of line on *persimilis*, basal side of discocellular 2 superposed black spots; tibiae and tarsi of all the legs wholly black, tibiae with rather long white hairs. Type: 1 ♀ from Monte Tolima in Mus. Berlin.

T. mentor Dyar (72 d). ♂. Body white. Palpi black outwardly, the fringe tipped with white; fringe *mentor*, below eyes black. Legs white. Wings dull white. Forewing; an antemedial dark point above median vein, and a short streak below base of vein 2; a fuscous spot at upper angle of cell, followed by a broad brown splash

with a dark point above it; three curved brown lines on interspaces between veins 2 and 5, gradually receding from outer margin. Wings below white. French Guiana.

- nigrisparsa*. **T. nigrisparsa** *Btlr.* (74 d). ♂. Head and body white, collar sometimes yellowish; a black spot on side of palpi; legs white with small black spots. Wings white. Forewing: three small black spots in an inbent line, two in cell, one below cell near vein 2; a series of black spots between veins 2 and 7, the spot between 5 and 6 inset close to cell. Hindwing white. Varies considerably in size. Amazons; Guianas; Colombia.
- modificata*. **T. modificata** *Drc.* (74 d). ♂. Head, collar, tegulae and abdomen wood brown, the latter with whitish hairs at base, underneath buffy brown. Forewing wood brown; an irregular white mark on discocellular preceded by a small black spot at lower angle of cell, and one beyond below vein 5. Hindwing paler, the base suffused with white. Forewing below darker, except on termen; the white mark larger, the inner margin broadly white. Hindwing below whitish with buff suffusions on costa. Carabaya, Peru.
- grisea*. **T. grisea** *Schs.* (74 d). ♂. Head and thorax buff white. Abdomen and wings avellaneous. Forewing: a white vertical line on outer side of discocellular. Forewing below the same, with inner margin whitish. São Paulo, Brazil.
- fusca*. **T. fusca** *Drc.* ♂. Head and body blackish gray, underneath clothed with dark grey hairs. Forewing blackish grey; a pale spot at end of cell. Hindwing grey, whitish at base. Forewing below black, the discal spot more distinct. Expanse: ♂ 37 mm. Santo Domingo, Peru.
- unicolor*. **T. unicolor** *Schs.* (74 d). ♂. Body and wings silky buff brown. Forewing: a minute whitish streak on discocellular; underneath paler; a small white spot at base of inner margin. Differs from *T. modificata* *Drc.* and from *T. fusca* *Drc.* in having no white at base of hindwing. Also close to *T. grisea* *Schs.* which has the inner margin of forewing below broadly white. Expanse: ♂ 29 mm, ♀ 47 mm. Castro, Parana.
- distincta*. **T. distincta** *Drc.* ♂. Body creamy white. Forewing pale fawn-colour, the margins white; a white mark at end of cell and one black spot beyond. Hindwing pure white. Wings below white; basal half of costal margin black. Santo Domingo, Peru.
- parmata*. **T. parmata** *Drc.* ♂. Head and thorax below white. Thorax, abdomen and wings fawn-colour; a black spot at end of cell on forewing. Rio Grande do Sul, Brazil.
- elmira*. **T. elmira** *sp. nov.* (74 d). ♂. Shaft of antennae white crossed by fine black lines, the branches cinnamon buff. Head and thorax below white; palpi laterally and fringe below eyes black; legs white with a few black spots. Thorax light buff. Abdomen white with some light buff shading. Forewing isabella colour; a white streak on discocellular partly edged by fuscous scales, preceded in cell by a small black spot and emitting a narrow white branch above vein 4 terminating in a black point. Hindwing white. Underside as above, but the forewing white from cell and vein 2 to inner margin, and no black spots near discocellular. Expanse: ♂ 35 mm. Ineachaca, Bolivia.
- rufidorsata*. **T. rufidorsata** *Drc.* ♂. Head, thorax and base of abdomen light brown; abdomen above bright red, laterally and underneath white. Forewing pale brown darker at apex; a black dot at end of cell, and one beyond towards margin. Hindwing pale brown, whitish at base. Santo Domingo, Peru.
- partalba*. **T. partalba** *Schs.* (74 d). ♂. Body white; some faint brown shading on abdomen dorsally. Forewing light ochraceous buff; base and inner margin whitish; an angled white spot on discocellular and below base of vein 5 edged with yellow ocher. Hindwing white faintly tinged with buff towards apex. Nova Friburgo, Brazil.
- votis*. **T. votis** *Schs.* (74 e). ♂. Head, collar and thorax white, the tegulae and abdomen light buff. Forewing pale ochraceous; costa light buff, the edge white; an angled white line on discocellular and below vein 5, longer below 5 than on discocellular. Hindwings white faintly suffused with buff white except on costa. Quirigua, Guatemala.
- roseidorsum*. **T. roseidorsum** *Schs.* (74 e). ♂. Palpi fuscous. Head, collar and thorax light buff. Abdomen above white at base then brilliant rose colour. Forewing light buff; a fine white line on discocellular surrounded by black suffusions in cell and interspaces between veins 3 and 7. Hindwing whitish buff. Joinville, S. E. Brazil.
- ochreata*. **T. ochreata** *Schs.* (74 e). ♂. Body and wings pale ochraceous buff. Forewing faintly darker towards apex and termen; a fine white line on discocellular, preceded and followed on interspaces by fuscous suffusions. Hindwing: costa whitish. The end of abdomen dorsally with purplish red hairs. Southern Brazil.

T. errans Schs. (74 e). ♂. Palpi, head, collar, tegulae and abdomen white. Thorax ochraceous. *errans*. Forewing ochraceous buff, interrupted by a wavy light cinnamon drab irregular line from above end of cell to inner margin near base; postmedial and subterminal lilacine shades define a very irregular line of ground colour; these are inbent from apex, strongly outcurved between veins 6 and 3 and inbent to middle of inner margin; veins mostly white, especially from cell to termen, the discocellular sinuous more broadly white; costa white irrorated with grey. Hindwings white. Cayuga, Guatemala.

T. amalita Schs. (74 e). ♂. Head, collar and thorax vinaceous cinnamon. Abdomen white, the dorsal *amalita*. tufts pink. Forewing vinaceous cinnamon crossed by two fine olivaceous brown lines; the inner line slightly inbent from costa, the outer line from apex to just beyond middle of inner margin. Hindwings white, the termen broadly shaded with roseate. Nova Friburgo, Brazil.

T. nox Drc. ♂. Described as being entirely black above and below. Santo Domingo, S.-East Peru. *nox*.

11. Genus: **Sarsina** Wkr.

♂. Palpi obliquely ascending, thickly scaled. Antennae deeply pectinated. Legs moderately hairy; hind tibiae with two pairs of spurs. Forewing broad; costal margin convex; apex rounded; termen slightly oblique; veins 2 and 3 apart towards angle; 4 from angle; 5 slightly above angle; 6 from below upper angle; 7—9 stalked; 10 and 11 free. Hindwing: costa slightly arched, termen rounded; vein 2 further from 3 than 3 from 4; vein 4 from angle; 5 slightly above angle; 6 and 7 from upper angle.

Most of the species of *Sarsina* are so variable and similar that they can only be separated through the genitalia. They form apparently good geographical races.

Type: *Sarsina purpurascens* Wkr.

S. purpurascens Wkr. (74 e). ♂. The specimen figured is pale pinkish buff, suffused with olivaceous, *purpurascens*. more intensely on the antemedial fascia, otherwise forming shades between the lines more pronounced at costa before the postmedial line and at apex. Hindwing light buff suffused with warm buff except at base. The ♂ are also buffish suffused with dull purple or hair brown. The antemedial fascia in all ♂ is followed by a fine double dark line, the outer one more distinct; postmedial line fine excurved at costa then slightly inbent to inner margin either straight or slightly sinuous; subterminal line fine sinuous. Frequently the hindwing is suffused partly or entirely with drab. ♀ less variable, the forewing has the double line forming a narrow fascia. Hindwing varies from almost white to drab. — WALKER's type came from Yucatan, so I have applied the name to those specimens which occur throughout Central America. — ♂ genitalia with harpes symmetrical, ventrally placed (opposed to tegumen rather than to each other), roughly rectangular in shape, slightly broader at extreme base and apex than at middle, apex sharply truncate, a single strong, central, outwardly curved thorn from apex and another shorter, straight thorn subcostally placed near and slightly behind the apex; uncus long, strong, triangular and broad at base, from middle to apex hook-like and scarcely tapering; tegumen a low, strongly chitinized, broadly-based arch; socii and gnathos absent; vinculum weakly chitinized; anellus a large, weakly chitinized, irregularly shaped and slightly curved plate with a pair of lateral arms which (as they also fuse with bases of harpes) may represent the basal elements of an undeveloped transtilla; aedoeagus long, stout (but much longer than broad), straight and tapering from intake of penis and with a slender, sharply curved blind-sae (part behind intake of penis) forming the basal third; penis with cornutus a large patch of closely set, short, fixed spines. (C. HEINRICH.)

S. violascens H.-Sch. (74 f). ♂. Forewing very similar to *purpurascens*; antemedial fascia followed by *violascens*. a narrow shade and a minutely wavy dark line; a well marked discal point; the sinuous subterminal line broken by veins. Hindwing cinnamon buff; a subterminal row of small dark spots. Hindwing below: subterminal spots better defined; a fine antemedial line from costa across cell, followed by a narrow dark shade to discocellular; a postmedial fine dentate line from costa to vein 2; the inner margin of both wings broadly yellow buff, the costal portion of hindwing suffused with purplish. Brazil; Paraguay. — ♂ genitalia as in *purpurascens* except: harpes larger, stouter, broadest about middle and from there tapering to apex; at apex of harpe a single short, curved thorn; another stouter, longer, straight thorn from costa near base. (C. HEINRICH.)

S. violetta sp. nov. (74 f). ♂. Forewings paler than *S. violascens* H.-S., the shadings pale olivaceous *violetta*. or lilacine. Hindwing buff white or white, the subterminal spots very indistinct. Expanse: 32 mm. Molinas, Paraguay. — ♂ genitalia with a pair of strong apical thorns on harpe. Otherwise as in *violascens*. (C. HEINRICH.)

festiva.

S. festiva Schs. (74 f). ♂. Body and wings cinnamon buff. Forewing: the lines very fine slightly darker like the apical third; a black discal point. Hindwing with faint subterminal points. Underneath the costal half of wings purplish chestnut, the inner half buff yellow; two pale medial streaks on costa, also post-medial line on costa; hindwing with faint postmedial and subterminal lines on dark portion. The ♂ specimen described in A. M. N. H. 1912 p. 40 belongs to *S. purpurascens* Wkr. ♀. Abdomen ochraceous buff. Forewing light ochraceous buff suffused with lilacine, purplish at base of costa and near lines; the lines fine, dark olive brown; antemedial line almost vertical; postmedial line straight, inbent; subterminal line wavy. Hindwing light ochraceous buff; a series of darker spots from apex to inner margin above anal angle. Underneath: forewing buff yellow suffused with purplish red; costa for two thirds from base pompeian red, crossed by two pale medial lines; the three lines dark, straight, the subterminal the broadest. Hindwing suffused with purplish red except on inner margin; darker medial, postmedial and subterminal lines; faint terminal spots. Expanse: ♂ 35 mm, ♀ 56 mm. *Costa Rica; Venezuela. — ♂ genitalia with harpes asymmetrical; left harpe with three outer costal thorns (one at extreme apex and two just behind in a row) and with a similar thorn on costa near base, right harpe with but two outer costal thorns, none of the thorns on either harpe appreciably curved; harpes shaped as in *violetta* and *violascens*; blind-sac of aedoeagus quite slender and but very slightly curved; cornuti very weak, nearly a weak-though extensive-seobination of the penis. (C. HEINRICH.)

electa.

S. electa Schs. (74 f). ♀. Body vinaceous fawn. Forewing deep purplish vinaceous, the base, outer edge of antemedial fascia, a broad medial shade, inner edge of postmedial and subterminal lines and the termen narrowly pale vinaceous lilae; lines straight except the sinuous subterminal line. Hindwing vinaceous fawn, darkest on termen. Forewing below vinaceous buff suffused with purple; costa partly, a broad shade before postmedial, and termen broadly vinaceous brown, the apex lilacine. Hindwing below with a broad vinaceous brown fascia inbent from beyond middle of costa, becoming narrow and obsolete towards inner margin, followed by a fine dentate line; basal half of costa and termen vinaceous brown. The specimen described in the Annals as the ♂ of this species is in reality a ♀ of *S. purpurascens* Wkr. Costa Rica.

dirphioides.

S. dirphioides Wkr. (= *quadristrigata* Fldr.) (74 f). This species is so similar to *S. purpurascens* Wkr. that no description would separate it. WALKER described a ♂ from an unknown locality. As it is impossible to examine the genitalia of the type in the British Museum I have associated with it the race that is prevalent in the Amazonian region and the Guianas. In case it is eventually found to be a synonym of one of the other, FELDERS name *quadristrigata* would stand. — ♂ genitalia with harpes long, reaching well beyond base of uncus, stout, longer than broad, with apices rounded and armed with long, heavy marginal thorns *) (some curved and some straight) and differing in number on the two harpes, four on the right and five or six on the left; each harpe also with a very short, slender thorn from costa close to base; aedoeagus and penis as in *festiva*. (C. HEINRICH.)

avertina.

S. avertina sp. nov. (74 f). ♂. Head and thorax wood brown; abdomen slightly paler. Forewings avellaneous, the darker shadings fawn colour; a narrow subbasal fascia; a fine line, almost medial, inbent, slightly outcurved across median; a black point at end of cell; a darker shade preceding postmedial, narrow from vein 3 to inner margin; postmedial outcurved below costa, fine, defined on basal side by pale scaling, partly white, followed between veins 3 and 5 by a dark patch; subterminal line black, fine, lunular near costa, and wavy, partly broken by veins; termen with an oblique pale shade from vein 3 across the subterminal line to vein 5. Hindwing wood brown suffused with hair brown; traces of a dentate line from apex, and subterminal blackish spots. Wings below avellaneous partly suffused with fawn colour. Forewing: costa dark reddish brown at base; a dark shade from costa crossing the black discal point; a fine postmedial line; subterminal spots above tornus. Hindwing: a black discal point, and a medial dark shade; postmedial line distinct, black, lunular dentate; subterminal black spots, two at vein 1 larger. Expanse: 37 mm. Coatepec, Mexico.

12. Genus: **Staetherinia** Btlr.

♂. Palpi obliquely ascending, thickly scaled, third joint almost porrect. Antennae pectinated to tips in type species the shaft fringed above with scales. Legs almost smooth; hind tibiae with 2 pairs of spurs. Forewing: costal margin very convex towards apex which is subfalcate; the termen excised between veins 7 and 5, below 5 almost straight to tornus; veins 2 and 3 equally apart from 4; 4 and 5 from lower angle; 6 almost

*) In this and other species of *Sarsina*, these „thorns“ are simply hooklike prolongations of the costa of the harpe and have nothing in common with the socketed modified spines found in some other families.

from upper angle; 7, 8, 9 stalked; 10 and 11 from cell. Hindwing: veins 2, 3, 4 apart; 5 close to angle; 6 and 7 from upper angle.

Type: *S. semilutea* Wkr.

S. semilutea Wkr. (74 g). ♂. Palpi rufous with dark tips. Frons dark brown. Thorax vinaceous *semilutea*. buff. Abdomen and hindwings light orange yellow, the abdomen with small dorsal black spots. Forelegs dark purplish brown. Forewing buffish thickly irrorated with lilacine scales producing a vinaceous buff colour; lines russet vinaceous, the antemedial and postmedial parallel, excurved at costa, straight and inbent to inner margin; two dark points on discocellular; subterminal line faint, but outwardly edged with white, lunular from costa to vein 5, then faintly inbent; costal edge, termen narrowly and cilia vinaceous brown, the latter white at base. ♀ with forewing uniformly fawn colour suffused with purple and without the white markings, the lines blackish. Expanse: ♂ 41 mm, ♀ 68 mm. Costa Rica.

S. dodona Drc. ♂. Forewing greyish olive crossed by three darker lines, and a subterminal row of *dodona*. black points. Hindwing light orange yellow with darker suffusions on termen. Described from figure in Biologia. Chiriqui, Panama.

S. valstana sp. n. (74 g). ♂. Shaft of antennae buff irrorated with ferruginous, the branches fuscous. *valstana*. Palpi ferruginous with dark tips. Thorax cinnamon drab. Abdomen antimony yellow; a dorsal tawny line extending on thorax. Forewing fawn colour suffused with purplish grey; lines slightly darker, finely wavy and inbent; an antemedial and two postmedial lines, the first curved around cell; a sinuous subterminal row of black spots partly edged with white; a large black spot at end of cell. Hindwing pale orange yellow; a small point at upper angle of cell and faint traces of three dark lines; cilia ferruginous. Wings below light orange yellow, the hindwing suffused with ferruginous except on inner margin; the three lines dentate purplish red. Expanse: 42 mm. Chiriqui, Panama.

S. corydona Drc. (74 g). ♂. Shaft of antennae ferruginous, the branches fuscous. Palpi deep corinthian *corydona*. red. Thorax wood brown. Abdomen ochraceous orange with a dark dorsal line. Forewing wood brown, the antemedial and two postmedial lines very sinuous, purplish brown; a subterminal punctiform black line, the spots towards costa well edged with white basad; a sinuous white line on discocellular. Hindwing orange buff, suffused except on costa with orange rufous; traces of dark lines, which on underside are purplish red, the medial and postmedial lines dentate, the subterminal punctiform, suffusing somewhat with the terminal shadings. Expanse: 40 mm. Canal Zone, Panama. It is with doubt that I make this the ♂ of *S. corydona* Drc., and should it prove distinct I suggest the name of **tarchona** for it.

S. cayugana Schs. (74 g). ♂. Head and palpi brown, the latter with black tips. Thorax and forewing *cayugana*. avellaneous; lines darker, the antemedial straight, inbent, the two postmedial lines somewhat outcurved and sinuous, very fine; subterminal line indicated by a few small black spots on interspaces, those towards costa and tornus with a few white scales; a white line on discocellular and a white point at origin of vein 4. Abdomen and hindwings yellow. Hindwing below darker yellow; a streak on cell dark purple; the three dentate lines purple, the medial not extending below vein 4. Expanse: 40 mm. Cayuga, Guatemala.

S. alyzia Dogn. (74 g). ♂. Shaft of antennae buff with purplish irrorations, the branches drab. Thorax *alyzia*. and forewing avellaneous. Forewing: an antemedial thick linear purple brown shade, inbent from costa, and a broad postmedial similar shade outangled opposite cell, followed by a fine black wavy line; another fine line medially between the two shades; some dark shading beyond the outer line, and a subterminal punctiform line. Abdomen and hindwing light ochraceous buff with some reddish suffusions; a fine dark postmedial line. Expanse: 23—28 mm. French Guiana.

13. Genus: **Porthetria** Hbn.

♂. Antennae bipectinated, the branches with terminal bristles, Palpi upturned, moderately scaled. Fore tibiae with long tufts; hind tibiae with two pairs of spurs. Forewing broad; vein 2 well before angle of cell; 3 near angle; 4 and 5 slightly apart from angle; 6 from just below upper angle; 7—10 stalked, 10 given off before 7; 11 free. Hindwing: veins 2—5 as on forewing; 6 and 7 from upper angle.

Type: *P. dispar* L.

P. dispar L. See Seitz Vol. II, p. 127. Introduced into the United States and doing considerable *dispar*. damage.

14. Genus: **Nygmia** Hbn.

♂. Antennae bipectinated, branches with terminal bristles. Palpi oblique. Legs hairy; hind tibiae with two pairs of spurs. ♀ with large anal tuft. Forewing: vein 2 well before end of cell; 3, 4, 5 from near angle of cell; 6 from or below upper angle; 7—10 stalked; 10 from beyond 7; 11 free. Hindwing: veins 3 and 4 stalked; 5 from above angle; 6 and 7 stalked.

Type: *N. phaeorrhoea* Don.

phaeorrhoea. **N. phaeorrhoea** Don. (partim *chrysorrhoea* Auct.). See Seitz Vol. II, p. 135. Introduced into the United States like the foregoing species.

15. Genus: **Desmoloma** Fldr.

♂. Palpi upturned, thickly scaled. Frons with long pointed tuft. Antennae pectinated for two thirds then serrate. Legs hairy, hind tibiae with two pairs of spurs. Forewing: costal margin straight; apex acute; termen oblique; inner margin straight; vein 2 well before angle; 3 close to angle; 4 from angle; 5 slightly above; 6 from upper angle; 7 and 9 absent; 10 and 11 stalked. Hindwing: costal margin straight from base then upcurved and produced to a hairy point, with an upturned tuft of hairs at middle of costa; from vein 8 to vein 6 the margin is excised between the veins, below 6 to vein 3 erenulate. Vein 2 well before angle; 3 and 4 stalked; 5 above angle; 6 and 7 from upper angle.

Type: *D. styracis* Fldr.

chironoma. **D. chironoma** Dyar (74 g). ♂. Body tawny, the thorax and abdomen above darker, the abdomen underneath white. Forewing tawny suffused with purple; some scattered black dots and striae; an antemedial darker curved fascia, its outer edge angled in cell, edged by a faint pale line; a round dark edged discal mark, filled in with olivaceous scales and partly surrounded by a white line; postmedial line dark, incurved at cell, and outcurved to tornus partly edged basad by a fine white line, not always present. Hindwing white, the costa broadly, the termen and inner margin narrowly like forewing. Expanse: 35 mm. French Guiana. —
pacha. **pacha** f. nov. ♂. Larger and slightly darker, the markings very indistinct. Abdomen below fuscous brown, only a few white hairs on anal segments. Expanse: 44 mm. Pacho, Colombia.

mollis. **D. mollis** Dyar. (74 h). ♂. Body vinaceous fawn, abdomen white below on basal half. Forewing light vinaceous fawn, with pale olivaceous brown striae and dots; antemedial fascia light brownish olive, edged with white, evenly curved on outer edge, not reaching costa; discal spot light olive, edged with white above; postmedial line fine, whitish, incurved below costa, and below vein 4 ending near middle of termen, outwardly shaded with light brownish olive, extending to termen at vein 3. Hindwing white, the costa and inner margin light vinaceous fawn, the termen narrowly so. French Guiana.

signata. **D. signata** Dyar (74 h). ♂. Thorax brownish olive. Abdomen above fawn colour, anal hairs buff. Thorax and abdomen below white. Forewing: costa narrowly, inner margin broadly from before middle to termen, and base light cinnamon drab; an antemedial small brownish olive spot on costa followed by a similar broad fascia from middle of wing at subcostal to inner margin near base, the basal interspaces below cell also brownish olive; discal spot U shaped, white filled in with russet; a russet shade from the fascia between veins 2 and subcostal to termen, somewhat darker beyond the postmedial line which is white, wavyly outbent from costa and excurved from vein 4 to termen at vein 2. Hindwing white, costa to near apex light cinnamon drab edged by a subterminal pale line, the apical triangular space brownish olive. ♀ broader winged, more uniformly coloured, the antemedial fascia, curved, expanding towards inner margin, edged and cut by white lines. Hindwing with the margins broadly dark cinnamon drab. Expanse: ♂ 37 mm, ♀ 45 mm. French Guiana.

styracis. **D. styracis** Fldr. (74 h). ♂. Body and forewings silky dresden brown. Forewing: the markings darker; a small basal triangular spot below cell; an antemedial small spot on costa; a narrow inbent fascia, partly broken into spots; a fine wavy medial line, followed by another irregular line from discal spot to inner margin; a fine postmedial line broader opposite cell, outcurved below vein 3, inbent and vertical across submedian; an oblique subapical shade with a downturned subterminal line; some striae scattered over the wing; discal spot orange yellow, partly edged with white. Hindwing white, the costal margin broadly dresden brown crossed by a darker subterminal shade. The ♀ similar, the lines on forewing replaced by numerous well marked striae; antemedial fascia very broad and dark, below submedian reddish. Hindwing with termen very broadly suffused with silky fawn colour. Venezuela; Colombia; Bolivia.

D. erratica Schs. (74 h). ♂. Head and thorax argus brown. Abdomen lighter brown. Forewing: *erratica*. more than basal third argus brown, limited by a reddish brown line; rest of wing slightly paler with a purplish tinge, with faint traces of medial, postmedial, and subterminal fine lines; a whitish discal point. Hindwings white, the margins broadly silky brown, darkest on costa. In some specimens the forewing is still darker, the fine lines imperceptible, in others the forewing is clay colour. Panama; Amazons; Venezuela; French Guiana. — This is the type of the subdivision *Mantruda* Schs., with veins 3 and 4 on hindwing not stalked.

D. modesta Dogn. (74 h). ♂. Body and forewings deep colonial buff, probably of a more greenish *modesta*. colour when fresh. Forewing: a medial black lunule below cell, and a short vertical line above inner margin; a black bar on discocellular; an outcurved lunular black postmedial line, followed by a faint dark line lunular on each interspace; termen slightly darker than rest of wing with some faint darker scaling on interspaces. Hindwing white; costa broadly cinnamon buff crossed by a black postmedial line preceded by a hair brown shade. Amazons. This species has the venation of *D. erratica* Schs.

16. Genus: **Blazia** nov.

♂. Antennae bipectinated. Palpi long and slender, obliquely upturned reaching above head. Fore legs moderately hairy; mid and hindlegs broken. Thorax and base of abdomen above with long hairs. Forewing broad; veins 2 and 3 stalked well before angle; 4 and 5 from angle; 6 from below upper angle; 7 and 8 stalked, 9 absent; 10 from angle close to 7; 11 free. Hindwing vein 3 nearer to 2 than to 4; 4 from lower angle; 5 slightly above angle; 6 and 7 from upper angle.

Type of genus: *Orgyia*? *lixivia* Dogn.

B. lixivia Dogn. (74 h). ♂. Head and thorax buff white with some scattered dark brown scales. *lixivia*. Abdomen brown above, buff white underneath. Forewing vinaceous buff suffused with brown, less so on basal half of inner margin; a white streak below cell from base; a subterminal fuscous line parallel with termen inwardly edged with a diffuse dark brown shade, emitting a fuscous streak above vein 5 to discocellular; base of veins 2, 3, and 4 white; terminal margin whitish, almost completely filled in with a silky drab gray shade, becoming brown towards inner margin; a terminal fine cinnamon line. Hindwing fuscous, slightly buff white at base. Expanse: 20 mm. Rio Songo, Bolivia.

17. Genus: **Phiditia** Möschl.

♂. Palpi upturned reaching frons, shortly but thickly scaled. Antennae pectinated to tips. Legs moderately hairy; hind tibiae with 2 pairs of spurs. Forewing: costal margin somewhat convex; apex acute; termen slightly rounded; vein 2 about middle of cell; 3 before angle; 4 from lower angle; 5 slightly above angle; 6 from upper angle; 7 absent; 8, 9, 10 stalked from cell just before angle. Hindwing: costa slightly convex; termen straight from vein 7 to vein 4, then lunular dentate; vein 2 from middle of cell; 3 and 4 from lower angle; 5 from middle of discocellular; 6 and 7 on short stalk.

Type: *P. diores* Cr.

P. scriptigera Dogn. (= *C. johanna* Schs.♀) (74 i). ♂. Head, collar and body pale ochraceous buff, *scriptigera*. the thorax suffused with vinaceous brown, the abdomen dorsally with reddish brown spots, surrounded by similar rings. Forewing pinkish buff suffused terminally with pinkish cinnamon, sometimes the whole wing suffused; a medial fascia suffused with brown, finely edged with black, its outer edge outbent and formed by the black line on discocellular which makes it appear outangled, then lunular and inbent; outer line, double, fine, lunular, the outer lunules above vein 5 with small hyaline white spots followed by a black line to apex. Hindwing with a conspicuous vertical fuscous line on discocellular; outer double line as on forewing. ♀ more of a light buff; medial fascia not so dark, its outer edge before the discal line, forming three lunules to submedian, then vertical. French Guiana.

P. diores Cr. ♂. Body hair brown. Forewing: basal two thirds benzo brown limited by a reddish *diores*. brown, outcurved, wavy line, crossed by two similar lines, antemedial and medial; terminal third light buff crossed by a postmedial outcurved even reddish brown line; subterminal dark-edged with semihyaline spots from costa to vein 3; a dark terminal line. Hindwing benzo brown to an evenly outcurved subterminal line,

crossed by antemedial, medial and postmedial wavy lines; termen light buff; a terminal dark line. Expanse: 48 mm. Surinam. This species is unknown to me and is wrongly identified in collections. Described from figure in CRAMER.

lucernaria.

P. lucernaria Wkr. (74 i). ♂. Head and collar vinaceous fawn. Thorax army brown. Abdomen above fawn colour, becoming paler towards anal segment. Forewing vinaceous fawn suffused with drab except on costa; basal, antemedial, medial and postmedial darker lines, the antemedial and medial outbent, incurved below cell, and more so below vein 2, the postmedial well beyond the two black spots on discocellular, slightly outcurved below costa, then vertical and lunular; a fine outer whitish line partly edged with black, followed by semihyaline spots, those above vein 5 narrower and outbent towards apex, those between 5 and 3 larger; termen fawn colour. Hindwing mostly fawn colour; double antemedial and a medial dark lines; the postmedial like outer line of forewing, followed by two semihyaline spots between veins 3 and 5. Colombia; Guatemala.

maculosissima.

P. maculosissima Dogn. (74 i). ♂. Palpi and thorax army brown. Head, collar and abdomen vinaceous fawn. Forewing vinaceous fawn; base vinaceous brown limited by the pale outwardly dark edged antemedial line which is outcurved to vein 2, then incurved and approaching medial line on inner margin; medial line inangled on subcostal, outcurved and touching postmedial at veins 4—2, then incurved; two black points on discocellular; postmedial incurved below costa, and deeply outcurved beyond discocellular to which it is much closer than in *lucernaria* Walk. and *maculosa* Dogn.; outer line whitish partly dark edged, outcurved at costa, then vertical, followed by hazel spots (not semihyaline) diverging above vein 5 to apex, the spots from veins 2—5 larger, all outwardly edged by a fuscous black line; termen vinaceous brown. Hindwing with faint hazel spots beyond postmedial line between veins 2 and 5. French Guiana. Intermediate between *P. lucernaria* Wkr. and *P. maculosa* Dogn.

maculosa.

P. maculosa Dogn. (74 i). ♂. Forewing differs from *P. lucernaria* Wkr. in having the discal mark linear, the spots beyond outer line less hyaline, except the three apical spots, and outwardly bordered by a fuscous black line. On the hindwing there are no traces of spots beyond the outer line. ♀. Head and thorax drab. Abdomen above cinnamon drab, with pale segmental lines. Forewing light drab; base largely cinnamon drab limited by a light drab strongly outcurved line, incurved below vein 2 and outwardly edged with cinnamon drab; a broad postmedial fascia, outcurved, broadest at costa, its outer edge wavy and with black spots or a line on discocellular; a more remote fine whitish outer line, outcurved from costa then almost vertical to inner margin; termen broadly light vinaceous drab with semihyaline spots close to outer line, but not reaching inner margin. Hindwing with broad cinnamon drab medial fascia; a fine postmedial hair brown line outwardly edged with whitish; terminal space broadly cinnamon drab suffused with purplish. There is considerable variation in the size of the hyaline spots on forewing. French Guiana.

cuprea.

P. cuprea Kaye. (75 a). ♂. Body and wings benzo brown with a silky gloss. Forewing: a fine, pale, antemedial line well outcurved from costa to above submedian then vertical; a similar outer line, outcurved below costa, slightly sinuous below vein 5; a small reddish brown spot on discocellular; a small yellowish spot near termen above vein 6. Hindwing: base of costa whitish; two pale lines on inner margin; a faint medial line, and a better defined postmedial line, slightly darker with pale edge on outer side. There is great variability in position and curve of lines, especially on underside, where the postmedial line either precedes, follows closely, or is remote from discocellular. Expanse: 35—60 mm. Trinidad, West Indies; Guianas; Costa Rica; Guatemala.

minor.

P. minor Schs. (75 a). ♂. Head and abdomen cinnamon drab, the latter dorsally suffused with benzo brown. Thorax benzo brown. Forewing mostly benzo brown with light greyish olive irrorations on inner side of antemedial line, on costa and between postmedial and subterminal lines; lines fuscous; antemedial and postmedial lines outcurved below costa, vertical below cell; postmedial lunular slightly outcurved at costa then vertical; a fuscous point on discocellular followed by a lunule from costa conjoined with medial line below it; costal edge tawny; a fuscous subterminal line outangled on vein 8, then incurved to termen at vein 3 followed by a tawny line between veins 6 and 8. Hindwing benzo brown, the outer half suffused with greyish; dark medial and postmedial lines. In some specimens the body and wings are fawn colour instead of benzo brown. Expanse: ♂ 29 mm, ♀ 39 mm. Trinidad, Paraguay.

18. Genus: **Tepilia** Wkr.

♂. Palpi upturned reaching middle of frons, thickly but smoothly sealed, slightly fringed in front. Antennae bipectinated to tips. Legs almost smoothly sealed; hind tibiae with 2 pairs of spurs. Forewing: costal margin straight, apex produced; veins 2, 3 and 4 equally apart; 4 from angle; 5 from above angle; 6 from

upper angle; 8, 9, 10 stalked; 11 free. Hindwing: costal margin almost straight; vein 2 just beyond middle of cell; 3 well before angle; 4 from lower angle; 5 slightly above middle of discocellular; 6 and 7 shortly stalked; 7 touching 8 near base.

Type: *T. biluna* Wkr.

T. biluna Wkr. (= *confinis* Wkr., *orbigera* H.-S.) (75 a). ♂. Head light drab. Thorax and dorsum *biluna*. of abdomen drab; dorsal cinnamon ocelli with a central cinnamon spot. Body underneath light drab. Forewing light drab; basal area limited by a wavy edged antemedial broad cinnamon drab fascia with dark edges; medial space with two black points on discocellular; postmedial fascia like antemedial, the edges more lunular; an oblique fine white line from apex; termen with darker suffusions towards tornus. Hindwing drab; a fine dark antemedial line; dentate postmedial and subterminal lines, the space between cinnamon drab; the lines terminating in dark streaks on inner margin. Rio de Janeiro, Brazil. Some specimens are brown, or pale as in the ♀ of *orbigera* H.-S.

T. fastidiosa Dogn. (= *joanna* Schs.) (75 a). ♂. Body light drab, the vertex whitish buff. Forewing: *fastidiosa*. base drab gray, medial space broad hair brown extending beyond cell, its inner edge incurved and bluntly angled basad above submedian, its outer edge lunular, wavy vertical; usually containing a large drab grey costal spot on which is a fine dark discocellular line, and smaller spots above inner margin; termen drab grey, darker shaded, terminally frequently forming a triangular space from close to apex to vein 2, almost as dark as the medial fascia. Hindwing buff white at base of costa, suffused in and below cell with light cinnamon drab; a dark postmedial band followed by a narrow drab grey shade; termen dark shaded. Tucuman, Argentina.

T. dodala sp. nov. (75 a). ♂. Head and abdomen wood brown. Thorax buffy brown. Wings cinnamon *dodala*. buff. Forewing: a medial mikado brown fascia formed by two thick lines, lunular dentate, partly broken, partly suffusing, outangled before the small discocellular spot, inbent to submedian, then curved to base of inner margin; a fine dark and faint postmedial line, outcurved around discocellular; a faint outer line outcurved below costa joined at vein 4 by a fine dark line from apex, this latter preceded by two slightly hyaline spots, and followed above vein 5 by a small fuscous spot. Hindwing: a fine postmedial and a subterminal lunular dentate line. Wings below with the terminal half suffused with darker cinnamon, the postmedial and subterminal lines well defined, the spots at apex of forewing white. Expanse: ♂ 38 mm, ♀ 44 mm. Cauca Thal, Colombia.

19. Gattung: **Rolepa** Wkr.

Same as *Olenoptera* H.-S. and *Athrula* Wkr. ♂. Palpi upturned, slender, reaching above frons; third joint short. Antennae bipectinated to tips. Legs with short hairs. Hind tibiae with two pairs of spurs. Forewing: costal margin straight; termen slightly rounded, oblique; vein 2 well before angle; 3 near angle; 4 and 5 from angle, or 5 slightly above, or rarely stalked with 4; 6 from below upper angle; 7 absent; 8, 9, 10 stalked; 11 from cell. Hindwing: costal margin straight; termen rounded; vein 2 from before middle of cell; 3 before angle; 4 from lower angle; 5 from middle of discocellular; 6 and 7 stalked; 7 anastomosing with vein 8 along middle third of cell.

Type: *R. delineata* Wkr.

R. delineata Wkr. (= *flavilimbata* H.-S., *saturnioides* Wkr.) (75 a). ♂. Body cinnamon brown, *delineata*. the thorax mottled with white hairs; collar and metathorax mottled with fuscous. Wings ochraceous tawny suffused with purple. Forewing: some yellowish suffusions at base; antemedial line pale yellow, outcurved to near middle of wing; a small chestnut spot on discocellular; postmedial line fine, dark, outangled between veins 5 and 6 closely followed by a fine whitish line, the two approximated at inner margin; subterminal line from near apex of ground colour edges the white line from vein 5 to vein 3; termen apricot yellow, narrow towards apex; a dark red apical point. Hindwing: termen broadly apricot yellow limited by the whitish, dark edged postmedial line; a faint darker medial line approximating the postmedial at inner margin. Underneath the postmedial line white, well defined on both wings. Brazil. The specimen figured in HERRICH SCHAEFFER is very small.

R. innotabilis Wkr. (75 b). ♀. Head and abdomen buffy brown, the abdomen with dorsal and lateral *innotabilis*. black spots and subdorsal cinnamon drab spots. Thorax and wings cinnamon drab, sericeous. Forewing: a fine dark antemedial lunular line, almost medial; a chestnut brown line on discocellular; postmedial line, outcurved beyond cell, wavy below vein 3, followed by a finer lunular line; a fine oblique subapical black line from below costa interrupting a chestnut brown line from apex forming a small and then a larger lunule

from apex, below vein 6 continuing as an almost straight line to vein 3; some darker brown hairs at base of inner margin. Hindwing: double antemedial and a postmedial chestnut brown short line on inner margin; a fine dark discal line and a wavy postmedial line, closely followed by a more distinct sinuous line, outwardly paler edged; termen suffused with vinaceous rufous. Underneath the pale outer line is nearer termen. The ♂ is rather paler in colour. Expanse: ♂ 38 mm, ♀ 54 mm. Venezuela.

erica. **R. erica** *sp. nov.* (75 b). ♀. Body and wings avellaneous, the latter suffused on termen with vinaceous. Forewing: antemedial line fine, darker; a fine chestnut brown streak on discocellular; postmedial and following line much closer to cell than in previous species; subterminal line from apex paler, inbent from apex and vertical to vein 3, inwardly white edged between veins 6 and 8. Hindwing: dark lines on inner margin as in nearly all the species of *Rolepa*; medial and postmedial lines near together, the latter finely dentate, followed by a dusky subterminal shade. Hindwing below with the postmedial line straight. Expanse: 42 mm. Argentina.

marginepicta. **R. marginepicta** *Dogn.* (75 b). ♂. Frons light drab; vertex whitish; thorax pale purplish grey; collar and tips of tegulae chestnut brown; abdomen dark grey with fuscous transverse lines. Forewing hair brown, largely irrorated with white scales, on costa at base, along costa to antemedial line and beyond this line to outer line; a fuscous streak along base of inner margin; antemedial line whitish outcurved; an outcurved medial fuscous line; a velvety fuscous black mark on discocellular inwardly edged by an inangled white line; postmedial line fuscous, outcurved, well defined; outer line fine white, well outcurved from costa inwardly finely edged with black followed by a chestnut brown line outbent to apex at vein 6; terminal area suffused with reddish brown becoming greyish towards apex. Hindwing whitish suffused with drab; a hair brown streak on discocellular, and a similar postmedial line inangled below costa; outer line white with dark edge; terminal area orange cinnamon, cilia chestnut brown with white spots. Expanse: ♂ 44–50 mm. The Guianas.

nigrostriga. **R. nigrostriga** *Schs.* (75 b). ♀. Palpi and frons light brown, vertex pale grey. Thorax and abdomen drab grey. Forewing pale drab grey; antemedial and postmedial lines filled in with light drab; a faint subbasal line; antemedial line double, sinuous, outbent to median, then vertical to inner margin; a black line on discocellular; first outer line, outcurved at costa, vertical below vein 5, minutely wavy, the outer line, outangled below vein 6, fine, straight, slightly inbent; a broad light drab terminal shade from vein 2 to apex preceded above vein 6 by a white and chestnut brown line. Hindwing: the lines as on forewing, the antemedial downbent from costa near base, curved to inner margin below cell; a hair brown line on discocellular. On both wings the outer postmedial line is narrowly edged on outer side with whitish. Expanse: 42 mm. Venadio, Mexico.

demerara. **R. demerara** *sp. nov.* (75 b). ♂. Thorax light drab, with a brown band posteriorly and the collar brown. Forewing pale drab grey, the lines filled in with light drab; an obliquely upbent fuscous black streak from base of inner margin; antemedial line hair brown, double, almost medial, the lines more widely apart on costa, outbent, curved below cell and again at inner margin; a chestnut brown small triangular spot on discocellular; postmedial line double, the first line outcurved, lunular, the second line fine, deeply outcurved beyond cell, then faintly incurved to inner margin; a broad terminal hair brown shade from vein 6 narrowing to tornus; an inangled line from apex with a fuscous brown vertical line between veins 6 and 8. Hindwing suffused with light cinnamon drab, the lines faint; antemedial hardly traceable, except by the two dark streaks on inner margin; first postmedial line very faint, the outer fine and well defined, slightly sinuous; some cinnamon drab shadings on terminal space. Expanse: 48 mm. British Guiana.

castrona. **R. castrona** *Schs.* (75 b). ♀. Body and wings russet vinaceous, the lines vinaceous brown. Forewing: an antemedial geminate line, outbent from costa to median and vein 2, the lines meeting on inner margin; a small dark line on discocellular; postmedial line finely wavy, outcurved around cell followed by a more distinct line parallel to it and outwardly pale edged; a dark subterminal line from vein 6 to apex, inwardly pale edged. Hindwing with only the outer lines as on forewing. Wings below similar, without the antemedial lines on forewing. Expanse: 41 mm. Castro, Parana, Brazil.

fiachna. **R. fiachna** *sp. nov.* (75 b). ♂. Body and forewings cinnamon drab with slight purplish suffusions. Forewing: base and lines darker; an antemedial line defined by the darker sealing, suffusing with an outbent lunular blotchy shade, inbent below vein 2; postmedial outbent from costa and curved well beyond cell; outer line fine, dark, outwardly pale edged, less outcurved than the postmedial; a subterminal dark shade from vein 9 to vein 3. Hindwing suffused with fawn colour except on costa; medial line hardly perceptible; postmedial line well marked, a continuation of outer line of forewing. Forewing below pinkish buff, the termen and hindwing suffused with cinnamon; faint postmedial and well defined outer line. Expanse: ♂ 39 mm. Manucapuru, Amazons.

R. unimoda Dogn. (75 c). ♂. Body and wings silky light buff; a fine, faint, darker outer line, slightly *unimoda*. outcurved at costa of forewing, then vertical. Underside similar with a fine line on discocellular. Expanse: 40 mm. Prainha; Santarem, Amazons.

R. sicyata Dogn. (75 c). ♂. Head and collar warm buff. Thorax cream colour in front, brownish *sicyata*. drab behind. Abdomen brownish drab, the second segment and part of first cinnamon. Forewing: anterior portion on basal third to within cell, then extending medially to submedian and within an incurved line from apex cream colour; basal and terminal areas brownish drab separated from light part of wing by a fine blackish line, the basal area with the line outbent to submedian, the outer portion with the line from near apex, excurved obliquely, below vein 5 incurved; from vein 5 at termen to vein 3 a lunular dark line encloses a wood brown space, no doubt greenish when fresh as stated in the original description. Hindwing cream colour; a faint dark postmedial line; termen broadly brownish drab from below apex. Expanse: 33 mm. Santa Cruz, Brazil.

R. medina Dogn. (75 c). ♂. Body cinnamon brown with some darker dorsal tufts on abdomen. *medina*. Forewings: base tawny with hair brown scaling in and below cell, limited by an antemedial white line, inbent on costa, outcurved across median vein and inbent to inner margin followed by a reddish brown parallel medial line, the space between tawny; a fuscous black spot on discocellular emitting a fine black line outangled at vein 4, the space around it to costa whitish buff; postmedial line hair brown from costa and outcurved, below vein 4 reddish brown, vertical; space beyond to outer line mostly tawny with a hair brown streak below costa; outer line fine, dark, lunular, outwardly well edged with white, which branches off at vein 5 to apex; termen broadly cinnamon brown. Hindwing mostly suffused with tawny brown on inner margin and outer half; a dark medial line; outer line white, minutely wavy. Medina, Colombia.

R. lojana Dogn. (75 c). ♂. Body hair brown, the abdomen with dorsal oval black lines on segments. *lojana*. Forewing light drab; a subbasal greyish olive fascia; antemedial line hair brown, outcurved, almost vertical below cell, followed by a medial line more remote below vein 2 than on costa, the space between deep greyish olive; a black point on discocellular; postmedial line hair brown slightly outbent from costa to vein 5, then parallel with medial line; outer line finer, less distinct, outwardly narrowly edged with white; termen deep greyish olive with two whitish spots from apex. Hindwing light drab; the dark postmedial line almost straight, a dark spot above it on inner margin; outer line as on forewing; termen with some darker shading and spots. Loja, Ecuador. This species and *R. medina* Dogn. have the hindwing slightly prolonged at vein 2, thus approximating *Phiditia* Moeschl.

20. Genus: **Sorocaba** Moore.

♀. Palpi short, upbent, hardly reaching frons, hairy, third joint small. Antennae pectinated to tips. Legs with short hairs; hind tibiae with 2 pairs of long spurs. Forewing: costal margin straight; apex rounded; termen somewhat oblique, rounded towards tornus; vein 2 well before lower angle; 3, 4, 5 from angle; 6 from below angle, the discocellular sinuous; 7 absent; 8, 9, 10 on long stalk; 11 from cell. Hindwing: costal margin straight; termen almost straight; vein 2 from nearer base than angle; 3, 4 from lower angle; 5 from near middle of discocellular; 6 and 7 stalked; 7 suffusing with 8 near base to beyond middle of cell.

Type: *S. anomala* Moore.

S. anomala Moore (75 c). ♀. Head and thorax vinaceous buff; a black line behind head; a chestnut *anomala*. brown band on thorax behind. Abdomen whitish gray with some brown irrorations, the basal segment white. Forewing: costal half to vein 3, then obliquely to vein 6 at termen light buff; inner margin wood brown; a large pinkish buff patch at base; a benzo brown shade from near base of inner margin expanding and filling the termen from vein 6 to near vein 2; a pale triangular shade at tornus; double antemedial and postmedial fine lunular dark lines almost vertical; a fine dark streak on discocellular. Hindwing dark brownish drab; a faint double, fine, lunular postmedial line; cilia reddish brown tipped with white on interspaces. Castro, Parana, Brazil.

The following two species, formerly included in the Lymantriidae were omitted from the Pericopidae where they belong.

21. Genus: **Leuculodes** Dyar.

♂. Antennae with long curly pectinations; palpi small, slender, upturned; proboscis well developed. Legs slender, smooth; hind tibiae with one medial and two terminal spurs. Forewing rather narrow; vein 2 further from 3 than 3 from 4; 4 from lower angle; 5 above angle; 6 close to upper angle; 7 and 8 stalked;

9 and 10 stalked; 11 free. Hindwing broad; costal margin straight; termen well rounded; veins 3—5 as on forewing; 6 and 7 stalked; 7 close to 8 to end of cell.

Type: *L. lacteolaria* Hulst.

lacteolaria.

L. lacteolaria Hulst. (75 c). ♂. Palpi, head, and collar pale yellow; shaft of antennae white, the branches fuscous. Body white. Wings white, thinly scaled. Forewings: basal third of costal edge fuscous; two fine parallel drab lines, the first from subcostal towards end of cell, inbent to inner margin at one third from base, the second from vein 10; 2 minute drab streak on discocellular. Expanse: ♂ 24—30 mm, ♀ 42 mm. Arizona; Mexico; Guatemala.

lephassa.

L. lephassa Drc. (= *dianaria* Dyar) (75 c). ♂. Differs from *L. lacteolaria* Hulst. in the absence of lines on forewing, and the branches of antennae are wood brown. Expanse: 26 mm. Mexico.

Note. In Stübel Reise p. 132, pl. 5, f. 9 a *Leucoma pasaleuca* is described and figured, but judging from the venation it is not a Lymantriid.

The type of *Microrgyia amazonum* Fldr. is lost as stated by Dr. K. JORDAN, its position therefore not to be ascertained.

Geometrodes mimica Fldr. is a Geometrid: as stated by Dr. K. JORDAN, the specimen is in good order and exhibits—in spite of vein 5 arising from lower angle of cell—the structures characteristic of Geometridae, a well developed proboscis, ocelli, the Geometrid abdominal tympanum etc.

Addenda.

We must add here the genus *Doa* *Neum. & Dyar* which stands in earlier lists as a Lymantriid Genus and will be looked for here; it belongs like *Leuculodes* to the Pericopidae, where it is omitted.

22. Genus: **Doa** *Neum. & Dyar.*

♂. Antennae with long pectinations. Hind tibiae with two medial and two terminal spurs. Venation as in *Leuculodes*.

Type: *D. dora* *N. & D.*

D. dora *Neum. & Dyar* (75 d). ♂. Thorax and forewing light drab, the latter frequently suffused *dora*. with hair brown on basal third, and terminal space; an antemedial black point in cell and on submedian vein; a more remote point below cell; a point in cell before end and two points on discocellular. Abdomen and hindwing drab or chaetura drab. ♀ with usually the medial area and a subterminal fascia drab grey. Guadalajara, Venadio, Mexico.

D. ampla *Grt.* ♂. Head and thorax silvery white, abdomen drab grey. Forewing silvery white with *ampla*. black points as in *D. dora*; costa fuscous black; a marginal fuscous black line interrupted by veins. Hindwing drab; a fuscous black terminal line less broken than in forewing; cilia white. Expanse: ♂ 30 mm; ♀ 40 mm. Arizona.

D. cubana *Schs.* (75 d). ♂. Head and thorax pale drab grey, abdomen drab. Wings thinly scaled. *cubana*. Forewing whitish; costal margin and termen narrowly drab; a broad light drab fascia from middle of wing to postmedial interrupted in cell; postmedial outwardly defined by white ground color, inbent from costa toward apex, and inwardly broadly shaded with drab from costa to vein 5; a black point on discocellular; a subterminal light drab shade from vein 5 to inner margin; cilia whitish with drab points at veins. Hindwings whitish suffused with drab grey. Matanzas, Cuba. Vein 9 on forewing is absent.

D. raspa *Drc.* (75 d). ♂. Head, collar and abdomen pale orange yellow; thorax white. Forewing *raspa*. white. Specimens from Venezuela have the forewing maize yellow or pale orange yellow; costa faintly suffused with pale orange yellow; lines fine, black; a double subbasal and an antemedial line angled or curved below costa; a fine line on discocellular; postmedial slightly outbent from costa to vein 5, then inbent; veins on terminal third with fine black lines; cilia and hindwing pale orange yellow. Mexico.

D. translucida *Dogn.* (75 d). ♂. Body drab. Wings thinly scaled. Forewing hair brown; medial *translucida*. and postmedial lines faintly darker, the space between them drab grey widest at costa; veins black. Hindwing hair brown, the veins black. ♀. Some yellow scaling on thorax; abdomen pale yellow orange with dark segmented shading. Wings thinly scaled, drab grey, the veins drab. Forewing: the two lines faintly darker, the space between whitish. Expanse: ♂ 27 mm; ♀ 43 mm. Colombia (Cauca-Valley, Popayan, Cali). This species should be transferred, I think, to *Leuculodes*, as I am unable to distinguish more than one medial spur on hind tibiae.

Family: Lasiocampidae.

The most essential characteristics of this family being represented in all the faunal regions have already been dealt with in the volumes 2, 10, and 14, to which respective passages we refer our readers. The American Fauna containing far more than 600 species probably supplies the greatest number which is by no means yet exhausted, since among every return from rather unknown districts a great number of new species are always discovered again. SCHAUS, for instance, only from his stay in Costa Rica brought along about 60 different species from the genus *Euglyphis* (*Claphe*), more than half of which proved to be new! On looking through the collections of the Berlin Museum almost 60 new Lasiocampid species were found, a great number of other species in the Senckenberg Museum, among the stock of species most kindly put at our disposal by Mr. BANGHAAS, and in the collections of W. HOPP, Charlottenburg, and of H. WERNICKE, Dresden. Thus nearly every important collection of exotic Heterocera still contains many species not yet described. Moreover, this fact shows how sporadically most of the species are taken, except of course some of the very common and widely distributed species. Most of the American species probably fly in the dark hours of night and are only to be captured by the lantern, except the ♂♂ of the genera allied with the *Tolyte*, which partly seek for their ♀♀ also in daytime, rapidly flying in the sunshine, in a similar way as the palearctic *Malacosoma alpicola*-♂♂ do. For this reason, the said ♂♂ are mostly represented in the collections by specimens that are almost unrecognisable owing to their wings having been too much damaged in flying and exhibiting merely hyaline rudiments, as for instance the *Titya proxima*, *nigrescens*, and *pallida*, which are difficult to capture in an undamaged condition. In daytime, *Lasiocampidae* may rarely be found; most of the species of the enormously large genus *Euglyphis* for instance, often exhibiting a bark-like exterior, are well protected and, in the confused jumble of the primeval forest, they are mostly very difficult to discover even for experienced collectors.

The distribution of the American *Lasiocampidae* on the continent is very characteristic. The North American faunal character is entirely like that of the palearctic regions. Above all we find here a group of large species allied to *M. rubi* and similar insects, then the smaller species of *Malacosoma* entirely corresponding to the European forms, and also a representative of the *Epicnaptera*-group; moreover, a few smaller species of the genus *Tolyte* occur, which probably represent forms parallel to our *Taragama*. In the southern and tropical latitudes the *Tolyte* form a very great contingent of partly also brighter coloured and particularly sexually very dimorphous forms. The greatest part of the forms, however, are distributed among the genus *Claphe* or, as it is now called: *Euglyphis*, which is unparalleled in any other faunal region. The more we go to the south, the more all these forms disappear in the same way as they do in the opposite direction towards Mexico. Far down in the south, in Chile, another group of forms appears showing numerous representatives, the species of *Macromphalia* which may be best compared with the *Chondrosteginae* which are otherwise entire strangers to the American Continent, although the structure is quite different. Some forms of the *Macromphalia*, being rather different from the generic type, extend up to Colombia.

We know but very little of the early stages of the tropical forms; we are much better informed of those of the North American forms. Also here we may refer to what has been said in the volumes of the other faunae. The larvae exhibit a highly developed structure and spinning capability, being mostly densely clothed with hair, besides tubercles with single hairs, and very frequently on the first ring with a short obliquely porrect fleshy cone, and on the rings 2 and 3 with the well-known decorative spot. Pencils are also occasionally found on several rings. Particularly in more southern latitudes we also meet with insects with genuine burning hairs.

Of the larvae of the *Eutachyptera psidii*, from which the old Aztecs obtained their famous „Mizteca-silk“, we are very accurately informed; HUMBOLDT already supplied a detailed description of them, and CARLOS C. HOFFMANN dealt with them at large in the Humboldt Publication of 1910, p. 149. This author, however,

does not agree with the general opinion that the old silk only originates from *G. psidii*, but supposes that particularly also *Saturnidae* such as *Callosamia*, *Telea* and *Attacus* are to be taken into consideration for it. The larva of *psidii* has hair which, like that of the larva of *rubi*, cause disagreeable burning sensations on the skin, especially on the back of the hand. Biologically interesting are also their enormously large nests „being particularly before the beginning of the rainy season of a glary white colour and often attaining a length of one meter“. The silk of *psidii* cannot be reeled off, but only combed.

The systematisation of the American *Lasiocampidae* does not cause the difficulties of other faunal regions, because there are fewer genera, part of which at least exhibit such a characteristic exterior that the enlisting of a species is mostly made rather easy. For this reason an analytical division of genera is also unnecessary, for the few principal groups are quickly and clearly identified. It is only difficult in certain cases to define *Tolyte* from *Titya*, as well as *Nesara* (*Ocha*) from *Euglyphis*. In America only the subordinate groups of the *Lasiocampinae* and *Malacosomatinae* in AURIVILLIUS' sense are represented.

Much more difficult, however, than the systematisation of the genera is the distinction of many species. This is chiefly due to the rareness of many species which are only known from single specimens and are often extraordinarily alike, and above all to the wrong identification of the types. The majority of the *Lasiocampid* types is now in the National Museum of Washington, after the Collection DOGNIN had been annexed to it, and chiefly owing to the great obligingness of Mr. W. SCHAUUS we succeeded to some extent in putting this difficult group in order. KIRBY, in his Catalogue, combined a great medley of insects that did not belong at all to the *Lasiocampidae*. A number of WALKER'S and FELDER'S types do not exist any more, so that we shall never succeed in perfectly clearing up all the questions. Mr. SCHAUUS greatly facilitated our task by grouping for us a synonymic list of the species contained in the Washington Museum, which afforded great difficulties, as well as by having a great number of species most perfectly painted for our plates by Mr. FRANCIS H. NOYES, so that we are able to figure such a great material as has never yet been put together. Mr. W. H. T. TAMS, in London, by examining the genital armature of doubtful species of *Prorifrons*, has contributed a great deal to clearing up this genus. All these facts prove that the American *Lasiocampidae* are still very inaccurately known and that by further examinations of the genital organs many questions must yet be solved, before we shall be able to specifically define numerous forms to a certainty. Then only a satisfactory grouping will be possible, which we must therefore leave to the future.

The *Lasiocampidae* are species of very large to small sizes, without a proboscis, with mostly short palpi, a hairy abdomen which is often very long in the ♂♂. The broad lobate projection of the costal margin of the hindwing often occurring in other faunae, is mostly quite absent in the American species. The discal cells of both wings are mostly narrow and short, the cross-vein of the hindwing is often very oblique. In both wings vein 5 rises from the lower cell-angles, vein 6 from the upper ones. The „basal cell“ being formed by 8 anastomosing with 7 on the hindwing is mostly very small or rudimentary.

1. Genus: **Gloveria** Pack.

Well characterised by remarkably little, hairy eyes, short porrect palpi, and in both sexes pectinate antennae, in the female with short pinnae. The abdomen is long, in the ♂ with a parted anal tuft. The veins exhibit few differences in all these large *Lasiocampidae*; on the forewing the cell is relatively narrow and short, 9 and 10 are stalked, 6 rises on a short stalk with 7 from the upper cell-angle, 4 and 5 from the lower cell-angle, 2 and 3 rise at about equal distances between the base and the cell-angle. On the hindwing 7 and 8 rise from a strongly developed basal noose, 4 and 5 on a rather long stalk rise together with 3 from the lower cell-angle. Both sexes are dissimilar, the ♂ is often scantily scaled in the disc.

The large *Lasiocampid* species have been carefully examined by BARNES and McDUNNOUGH, whereby they had to be divided into various genera, the arrangement of which was fundamental for our work.

Type: *G. arizonensis* Pack.

arizonensis.

G. arizonensis Pack. (76 a) is easily recognisable by the strong black neuration and the extraordinarily strongly notched subterminal line; both the transverse lines are rather distinct, particularly the posterior line which is pointedly inwardly dentate on the veins and between them projects feebly rounded distally; discal and marginal areas usually darkened, in the former a distinct white discal spot. — f. **dolores** N. & D. is based upon specimens in which the subterminal line is not uniformly parallel to the margin, but is bent towards the base above the anal angle and between the radials. Nothing has yet been published about the larva, although the species has already been bred. Colorado, Arizona, South California.

G. edwardsii *Drc.* is allied to the preceding species in the male, but it has a somewhat less dentate *edwardsii*, and less prominent subterminal line; the ♀ almost resembles more *gargamelle* *Stkr.* by the subterminal line receding still more and the transverse lines showing a less oblique course, the anterior line being somewhat more removed towards the discal area. Mexico (Durango, Jalapa, Orizaba).

G. venerabilis *Edw.* (76 a) is very similar to *edwardsii*, but it is lighter, the grey postmedian band is *venerabilis*, more regularly dentate and the submarginal line more coherent and uniform. Mexico (Jalapa).

G. olivacea *Edw.* (76 a) looks quite different owing to its intense whitish hairing and strewing on *olivacea*, the coffee-brown ground; median band and marginal area of a purer and darker brown, the latter defined towards the postmedian area by a still darker spotted subterminal line which projects in a large bow towards the margin between the lower subcostal branches; the white discal spot may be very large, but it may also be very much reduced by the darkened bordering; in the subterminal area there is a more or less distinctly prominent darker median line. The ♂ is apparently very much rarer and very scantily scaled in the disc, the hindwing exhibits a lighter postmedian area. Mexico (Orizaba, Jalapa, Misantla, Coatepec).

G. howardi *Dyar* (78 a) is the smallest species, the ♂ somewhat similar to that of *olivacea*, but more *howardi*, yellowish-brown with a reddish tint, with quite indistinct markings; the ♀ is more similar to that of *D. coronada*. Arizona. — The larva lives on *Quercus emoryi*.

G. sphingiformis *B. & McD.* (78 a) is very conspicuous by the narrow long forewing with a concave *sphingiformis*, distal margin. The only ♂ known hitherto is chocolate-brown, its base and cell being darkest, in the disc semi-transparent with a white cellular spot and a strongly dentate subterminal line projecting far towards the base between the lower radial branches and being inwardly, in the upper half, more or less bordered with yellowish-white. Hindwing unicoloured chocolate-brown. — Texas (Kerrville).

G. gargamelle *Stkr.* (= *arizonensis* *Edw. nec Pack.*) (78 b). The nomenclatural type is of a bright *gargamelle*, brown, but usually more blackish-brown, similarly marked as the preceding ones, with but slightly darker median and marginal areas, the ♂ in the disc extensively diaphanous, on the hindwing with a broad light, scantily scaled postmedian band. — If the marking is indistinct, it is the form: **medusa** *Stkr.* — Arizona, South *medusa*, California.

G. concinna *Dyar* (76 b) resembles the ♀ of *gargamelle*, it is lighter or darker red-brown or also more *concinna*, greyish-brown, densely clothed with light yellow hair, with brown transverse lines, the posterior line outwardly with a fine lighter border, with a small white cellular spot adjacent to the proximal transverse line; the brown subterminal line is very indistinct. — In the form **rubicundens** *Dyar* the transverse lines are more distantly *rubicundens*, separated. Only the ♀ is known. Mexico (Zacualpan).

G. obsoleta *Dyar* is very dark brown, with whitish hair and strewing, dark indistinct transverse lines, *obsoleta*, of which only the distal one is better visible, and with a feeble whitish discal spot. Ends of fringes on both wings white. Expanse of wings: 67 mm. Described from a ♀ from Mexico (Hidalgo).

G. sodom *Dyar* (78 b) has also dark brown forewings intensely white-haired, with 2 broad dark *sodom*, transverse bands, both separated afar, the distal one curved, between them a faded spot; the dark subterminal line is irregular, above the anal angle and between the radials inwardly indented; ends of fringes white. Mexico (Hidalgo). Only the ♀ is known.

G. latipennis *Dyar* (78 b) is somewhat smaller than the preceding ones, chocolate-brown, strewn *latipennis*, with white, the median area in the upper three quarters without strewing and representing a dark band, enclosing a round white contrasting discal spot; the subterminal line is composed of a curved row of brown, small internodal spots. Hindwing dark brown, ends of fringes yellowish-white. Mexico (Jalapa).

2. Genus: **Neoborocera** *gen. nov.*

Very closely allied to the genus *Gloveria* and chiefly distinguished by the quite different conspicuous shape of the wings, the abdomen projecting far beyond the hindwing, and a very deep concavity of the costal margin of the hindwing. Besides 7 and 8 rise together with 6 on a stalk. The only, very peculiar species was placed to the Ethiopian genus *Borocera* by its author, but it is better ranged separately.

Type: *N. esteban* *Dogn.*

N. esteban *Dogn.* (76 c). Forewing deep brown, in the subterminal area lighter, at the costal margin *esteban*, broad, at the hindmargin narrow, with a small light cellular spot. The peculiarly shaped hindwing exhibits a yellowish-white distal margin. Ecuador.

3. Genus: **Eutachyptera** B. & McD.

It has larger hairy eyes, but it is otherwise very similar to *Gloveria*, only the basal loop of the hindwing is somewhat smaller. But one species.

Type: *E. psidii* Sallé.

psidii. **E. psidii** Sallé (76 b) is the well known Mexican species, from the cocoons of which the so-called Mizteca-silk was produced. Forewing red-brown, in the ♂ darker, in the ♀ lighter, more yellowish, with 2 light yellowish transverse lines and a small white, in the ♀ mostly indistinct discal spot between them. Also the hindwing of the ♂ exhibits a light curved postmedian line. Arizona, Mexico to Guatemala. — The brown larva set with silky soft rosy hair lives in colonies of 80 to 100 specimens in a glary white nest extending to one meter length, feeding only at night, from October to April on Guayavae and various species of oak.

4. Genus: **Caloecia** B. & McD.

Distinguished from the preceding genus by the veins 4 and 5 of the forewing not being stalked. The distal margin of the wings is slightly undulating; otherwise very similar. The ♂ exhibits on the anterior tibiae a well developed epiphysis, being quite undeveloped in *Gloveria*. Two species occurring from the southernmost parts of North America to Mexico.

Type: *C. juvenalis* B. & McD.

juvenalis. **C. juvenalis** B. & McD. (78 a) may only be a local form of the following species. Forewing in the basal half deep brown, outside densely strewn with grey, with a broad chocolate-brown median band with a small white cellular spot in blackish scaling which extends as a longitudinal band from the base almost to the subterminal line being composed of black sagittary spots; between it and the distal edge of the median band there is another dentate light grey line. Hindwing red-brown with a somewhat lighter distal band. Arizona. The ♀ is lighter and less contrastingly marked. Arizona.

denda. **C. denda** Drc. (76 d) is on the forewing and hindwing very dark brown, with a small white cellular spot and 5 narrow light greyish-brown, more or less distinctly black-edged notched lines, two of which are near the base, two being postmedian and the 5th submarginal, the latter with small black sagittary spots, the subterminal area being reddish-brown. Hindwing with two feeble reddish-brown lines. Mexico (Jalapa).]

5. Genus: **Quadrina** Grt. !

Separated from all the neighbouring genera by vein 10 of the forewing terminating distantly remote from the apex into the costal margin and vein 9, which is stalked with it, almost directly into the apex. The eyes are larger and more projecting than in *Caloecia*. The basal loop of the hindwing forms a very much longer accessory cell, all the rest is as in the preceding genus. But one species.

Type: *Q. diazoma* Grt.

diazoma. **Q. diazoma** Grt. (= *oweni* Barnes) (78 b) is very much like *D. coronada* and, excepting the morphological differences, separable by the equally broad median band which in *coronada* is twice as broad at the costal margin as at the hind-margin. Forewing red-brown intermixed with light grey or yellowish-white hair-scales; the dark lines bordering on the discal area which forms a somewhat re entering angle on the penultimate subcostal branch, are on the averted sides bordered with a somewhat lighter colour; right behind the anterior line there is the small white cellular dot; behind the subterminal line, which is bordered by a more or less light colour, there is a row of small dark internerval spots; New Mexico, Arizona.

6. Genus: **Prorifrons** B. & McD.

A genus containing numerous species part of which are very difficult to identify and very closely allied to one another, hitherto found from Mexico to the south as far as Colombia, Bolivia, and Brazil. The genus is characterised by the relatively long palpi projecting like beaks or snouts. On the forewing veins 9 and 10 rise on a short stalk; the former terminates directly into the apex, the latter below it into the distal margin. The other veins are as in *Quadrina*, though 11 and 2 rise nearer at the base; on the hindwing 4 and 5 rise either together or on a short stalk from the lower cell angle. — The greatest difficulties were caused by the wrong identification of the types; Mr. SCHAU in Washington and Mr. TAMS in London, as well as Mr. JOICEY, the owner of DRUCE's types most kindly and largely helped us in clearing up and rectifying these mistakes, and we therefore beg to express at this place our special thanks. I think it will be possible by the aid of our

figures to identify the species rather surely, so that on this basis the progress of this extraordinarily difficult genus will be facilitated.

Type: *P. quadrilineata* B. & McD.

I. Sect. Transverse lines not undulatingly dentate.

P. lineata Maass. (76 c) has comparatively broad forewings with a slightly oblique, rounded distal *lineata*. margin and an obtuser apex than the other species, ground-colour darker, browner, very coarsely strewn with greyish-yellow, the median area narrow, its distal border-line forming below the costal margin an almost right, somewhat rounded angle; the subterminal area is not darker than the postmedian area, only the marginal area is feebly darkened, the row of the subterminal lunae forming a coherent light line twice projecting distally. The costal margin of the hindwing is hardly concave, 2 lighter transverse bands are distinctly prominent. The abdomen is relatively shorter than in the similar species. Colombia, Ecuador, Bolivia. — It seems very doubtful whether **quadrilineata** B. & McD. is specifically different. The name may be maintained at the most for the *quadrilineata*. northernmore specimens appearing somewhat more olive brown owing to the intenser grey admixture, the median area being usually somewhat darker. The hindwings are of almost the same colouring as the forewings, in *lineata* of a decidedly redder tint. Described from Mexico.

P. antonia Schs. (76 b) is very similar, smaller, dark red-brown, just as coarsely strewn with yellowish, *antonia*. distally lighter veins, lines as in *lineata*, though in the specimens at hand and in the figure of the type kindly put at our disposal by Mr. SCHAUUS the distal border of the median area forms a larger rounded bow below the costal margin. Hindwing violettish-brown. Costa Rica.

P. castullux Dyar (76 e) has decidedly narrower wings, with a much narrower distal margin, the colour *castullux*. being a darker ol ve-brown, often almost blackish; less coarsely strewn, more smoothly scaled; lines more oblique than in *lineata*, the median area hardly darker, the black anal spots variable, often almost absent, the upper spot much farther inwards than in *lineata*. Panama to Colombia. — As **barnesi** f. nov. (76 e) I denote *barnesi*. a much smaller lighter form with a prominently darkened median area which is narrower towards the hind-margin. The costal margin of the hind-margin is much deeper concave. Mexico. Type in the Coll. DRAUDT.

P. doeri Schs. (= *boliviana* Dogn.) (77 a, 86 b) has still longer and narrower wings than the two preceding species, with a very oblique distal margin, the costal margin being very convex towards the apex, so that the apex of the wing is somewhat falciform. Deep red-brown, with feeble yellowish veins, almost straight and very oblique transverse lines, the median area being at the costal margin 3 to 4 times as broad as at the hind-margin and only slightly darker than the ground; the subterminal area particularly analwards lighter reddish-brown; the two black anal spots are mostly very thick and large. The distal margin of the darkened black hindwing with 2 lighter undulated transverse bands is slightly rounded, the costal margin flatly concave. Abdomen very long. The ♀ is duller brown, the lines less oblique, the median area more equally broad, the anal spots small. Bolivia, Colombia. *doeri*.

P. angustipennis Sch. (77 a) is an extreme species of the preceding one with an entirely Sphingid *angustipennis*. habitus, with still narrower and longer wings and a longer abdomen. On the dark ground of the forewing the markings are quite indistinct, only visible as two nebulous darker transverse bands, the small cellular spot ochreous. Costa Rica.

P. phedima Stoll, according to SCHAUUS' assertion, is a *Prorifrons*; we insert the unknown insect here, *phedima*. because the figure also shows two oblique darker nebulous bands in contrast with the other representatives of the genus. The shape of the figure (evidently according to a ♀) is the most similar to that of *quadrilineata*. Surinam.

P. gustanda Dyar (76 d) has almost the same shape of the wings as *doeri*, but the distal margin of *gustanda*. the hindwing is more rounded and slightly waved; the colour is light reddish brown, in the cellular areas variably strewn with blackish, with yellowish veins, intensely intermixed with whitish-grey hair-scales; median and marginal areas hardly darker than the ground. Lines as in *doeri*, but the median area is more equably broad, the blackish, narrow discal longitudinal patch distinct, prolonged almost to the base, the small yellowish subterminal lunae are feeble, the anal spots tiny or absent. Hindwing of a bright red-brown colour. Ground-colour of ♀ much lighter, reddish-brown, the hindwing particularly light. Mexico. The penis is somewhat similar to that of *conradti*, with 2 very long spines.

P. tamsi sp. n. (76 d) is above strikingly similar to *gustanda*, so that it is unnecessary to describe its *tamsi*. colour and marking; but the species is of only half the size with broad wings, a straighter distal margin and a much shorter abdomen, almost as in *lineata*. The costal margin of the hindwing is straight, in *gustanda* deeply concave. The marking of the hindwing beneath is very different; the basal half of the hind-margin is occupied by a deep dark brown triangle above which there is another red-brown triangle at the base in the yellowish-white costal-marginal half; in *gustanda* the hindwing beneath is monotonously light reddish-brown. Mexico (Zacualpan). Type in the Coll. DRAUDT.

peruviana.

P. peruviana Drc. (76 e, 77 b) is probably the most easily discernible of all the species. Forewing broad, blackish red-brown, in the anal quarter contrastingly light brown with reddish-yellow veins; the double lines bordering on the broad median area are so very close together as in no other species; the white discal spot is very large and bright in the black discal longitudinal patch; 2 anal spots almost vertically above each other are deep velvety black and very large. Hindwing dark red-brown with almost pure white fringes. The ♀ is much lighter. Peru, Bolivia (Chaco).

songoensis.

P. songoensis sp. n. (77 b) has the same marking as *peruviana*, but broader wings. The ground-colour is a lighter yellowish-brown with a still lighter anal quarter and reddish-yellow veins; the double lines bordering on the median area are not so close together, the blackish-grey discal longitudinal patch is intense, the white cellular dot feeble like the two small black anal spots; hindwing light reddish yellowish-brown, its anterior angle much more prominent than in *peruviana*, and the abdomen is much shorter. According to a ♂ from the Rio Songo (Bolivia); type in the Berlin Museum.

rufescens.

P. rufescens Schs. (77 c) is the most similar to *castallux* as to the shape of the wings, but the apex of the forewing is more rounded. The colour of the wings is a light yellowish red-brown, only slightly intermixed with whitish-grey, the transverse lines curved as in *peruviana*, but more separated; the narrow blackish discal longitudinal stripe extends from the tiny white discal dot to the subterminal line being composed of yellowish spots which are centred near the apex with 2, analwards with 2 or 3 black spots which, however, may be indistinct; the median area is of a rather pure red-brown, the subterminal and marginal areas somewhat darker than the postmedian area which is intermixed with whitish-grey, the marginal area particularly analwards powdered with a delicate lilac-grey. Hindwing reddish-brown with lighter fringes. Costa Rica. A specimen from the Coll. STAUDINGER, labelled „Mexico“, shows a somewhat more olive tint.

hoppi.

P. hoppi sp. n. (77 a, b) is a beautiful species closely allied to *rufescens*; the red-brown forewing exhibits particularly the antemedian and postmedian areas very much intermixed with whitish-grey hair-scales, especially at the hind-margin; the curved lines are prominent almost white, the blackish longitudinal stripe through the cell-end, enclosing the small white cellular dot, almost extends to the subterminal line which is composed of a more or less complete row of black small spots inwardly bordered with yellowish. Collar contrastingly whitish-grey, also the thorax very light. Hindwing red-brown with almost white fringes. The ♀ is much more uniformly red-brown hardly intermixed with whitish-grey. Described from 2 ♂♂ and one ♀ from Chachatoy (Colombia), 2300 m. Type in the Coll. HOPP, Charlottenburg.

II. Sect. Transverse lines, at least the postmedian one, finely dentate towards the costal margin.

championi.

P. championi Drc. (77 c, 86 a). The identification of this species which was long misunderstood has caused the most difficulties, because beside the type, the photo of which was most kindly put at our disposal by the Brit. Museum, apparently at least no other specimen exists. It is allied to the two preceding species from which it is separated by the small fine dents of the postmedian line below the costal margin; the shape of the wings is broader, the apex rounder, the whole insect smaller; the colour is a soft brown, the antemedian and postmedian areas are just as broad as the somewhat darker median area which is almost broader at the hind-margin than at the costal margin and projects a little below the submedian fold on both sides rounded; the tiny blackish subterminal spots form an almost complete, slightly S-shaped row. The figure in the Biologia is deceptive, the description futile. Described from Panama. In contrast with *conradti*, the accessory spine at the penis is situate almost as high as the main spine, and in the concavity between both there is another small plain spine and a bicuspid spine. The ♀ figured on pl. 86 a we have placed here only as the presumable ♀. It originates from Ecuador.

tremula.

P. tremula Schs. (77 c). Here begins a very difficult group of closely allied and variable species extraordinarily allied to *championi*; their sure identification will therefore only be possible by examining the peculiarly shaped genitals, the more so since the similar species vary also in the same direction. *tremula* is rather large, the basal area as far as the darker median area brown, strewn with yellowish-reddish, traversed by a darker waved line proximally bordered with a lighter colour; the white discal dot is very small; the postmedian and subterminal areas are lighter than the basal area, traversed by an undulatingly dentate, distally light line, passing over without a distinct border into the yellowish ochreous subterminal spots, projecting scalariformly especially in the centre and subanally, each of them being outside spotted blackish; the marginal area behind it is strongly mixed with grey. Hindwing dark brown with hardly lighter fringes and traces of two lighter transverse bands. Costa Rica to Colombia.

crenulata.

P. crenulata sp. n. (86 b). There is but one faultless ♂ before me, for which I am indebted to Mr. BANG-HAAS; without examining the genitals, it is therefore impossible to ascertain whether it is only a form of *tremula*. Forewing and hindwing not entirely margined as in *tremula*, but decidedly undulatingly margined. Ground-colour redder, hindwing almost copper-coloured, with whitish tips of the fringe. On the forewing the subanal line is similarly shaped as in *tremula*, the median area about thrice as broad, the line defining the

postmedian area against the subterminal area much more distinct, blackish and particularly in the upper half much more strongly dentate with distally projecting round bows; subterminal markings almost as in *tremula*. Colombia. Type (♂) in the Coll. BANG-HAAS.

P. prosper Dyar (78 d) is quite an uncommon variable insect, very similar to *tremula*, somewhat *prosper*. smaller, in the form which I consider to be the type light red-brown, before and behind the median area very much mixed with yellow, the subbasal line shaped as in *tremula*, the median area at the costal margin more than twice as broad as at the hind-margin, between 8 and 9 distally four times as broad and here very denticulate, towards the hind-margin in the centre of a very light yellowish-white; discal dot very small, on the proximal border of the median area; on the border between the postmedian area and the decidedly yellow subterminal area there is an intense double red-brown wavy line filled with light; marginal area reddish-grey, subanally and between 4 and 6 extending notched into the yellow subterminal area; the row of black dots is complete, the two anal ones and apical ones being the largest. Hindwing brownish-red, fringes with whitish tips. The ♀ (77 d) of which we are able to figure the type is compared with *conradti* by the author, but it seems not to have been the genuine *conradti*. DYAR writes that *prosper* has much narrower wings, the hindwing being less deeply concave at the costal margin; the markings are much more distinct without the faded yellowish areas; body beneath not so dark blackish-brown, the subterminal spots more irregularly arranged. Mexico. — **pini** *pini*. *f. n.* (78 d) I denominate an extremely grey-dusted form, only the subterminal area being yellowish reddish, the total colouring being softer, smoother, all the lines somewhat finer, the black discal patch feebler; thereby a remarkable resemblance to certain *D. pini* from Europe is produced. The genital organ is quite the same in both forms: at the penis between the main and the vesical spine a concavity exhibiting like a comb 4 more, slightly curved parallel spines gradually decreasing in size towards the main spine; the vesical edge of the accessory spine exhibits on a slight convexity 4 more, smaller spines, so that this insect shows an extraordinarily complicated spining which cannot be mistaken for any other species known to me. Mexico (Orizaba; Cordoba), type in the Coll. DRAUDT.

P. costaricensis *sp. n.* (77 d) is the most similar to *prosper* in the genital organ, but very different in *costaricensis*. the exterior; much smaller and of an almost monotonous greyish-brown ground-colour, lighter than in *mülleri*, all the lines, as well as the border of the median area, indistinct, shadow-like, the subbasal line shaped as in *tremula*, the median area relatively very narrow, in one of the two specimens at hand only few millimeters broad, the white discal spot almost extinct, particularly the distal border-line very undulatingly dentate, still more so the postmedian border-line which is distally bordered by a light line; the small blackish subterminal spots are very feeble, hardly shadow-like. Hindwing somewhat darker, more intensely coppery, the ends of the fringes whitish. According to 2 ♂♂ from Costa Rica in the Coll. BANG-HAAS. — **seitzi** *f. n.* (78 e) is specifically *seitzi*. not separable owing to the genital organ, but it looks quite different and is very similar to *prosper* by the bright red-brown colour which is more rusty yellow basally and behind the median area; in the marking otherwise the same, the median area is somewhat broader, the white discal spot stronger, the contrast between the rusty yellow subterminal area and the greyish-brown marginal area much more prominent, the small black spots stronger. According to 1 ♂ from Gramal near Muzo (Colombia); type in the Mus. Senckenberg. The penis is not dissimilar to that of *prosper*, but much smaller and neater, the concavity between the spines very much deeper containing but 2 very feeble small spines, at the upper edge of the vesical convexity with 2 somewhat larger dents, below them with 3 tiny dents.

P. vibrans Schs. (77 c, 86 a) is very similar, smaller, the median band narrower, distinctly darker, *vibrans*. the transverse lines at the costal margin more distinctly denticulate, lighter, more distinctly bordered with dark, the median area above the hindmarginal vein on both sides convex, the subterminal spots distinct, roundish, more or less completely centred with blackish. Hindwing dark copper-brown. Costa Rica.

P. conradti Drc. (77 d) is one of the largest species; reddish-brown, all the transverse lines finely *conradti*. undulatingly dentate, the median area particularly at the costal margin broad, at the hind-margin narrower, distinctly dark brown or blackish-brown, the white discal dot on the proximal border, the blackish discal longitudinal stripe narrow; subterminal line not broken up into dots but forming a yellowish-ochreous band which is proximally indistinctly, distally distinctly defined, enclosing small black spots, only the anal ones of which are more distinct, the upper spot receding far; between the median area and the subterminal band there are besides two undulating darker brown lines; marginal area somewhat greyer, projecting in the centre between 4 and 6. Hindwing red-brown with distally whitish fringes, the light transverse lines very distinct. Mr. TAMS had the kindness to send me a photo of the genital organ of the type which has apparently remained unique. Accordingly, the penis which is very characteristic for every species exhibits, at the proximal end opposite the vesica, as in all the *Prorifrons*, a very strong spine-like appendage with a single shorter accessory spine in the centre of one edge. Described from Guatemala. From the Coll. BANG-HAAS I have a much flown specimen at hand from Marcapata, which is very much like the figure of the type, but without examining the genital organ nothing can be said in this most difficult group.

- mülleri*. **P. mülleri** *sp. n.* (78 s) is a large species with relatively very broad wings, of a dark, more greyish-brown colour, strewn with yellowish-grey, the darkest in the median area, in the subterminal area more reddish-brown, at the distal margin strewn with violettish-grey, but all the colours not very much contrasting; subbasal band broad, shadow-like blackish and extending to below the cell, median area moderately broad, at the costal margin about twice as broad as at the hind-margin, the border-lines hardly waved, the white discal dot tiny, close in front of the median area; the border-line between the postmedian and subterminal areas faint, blackish, distally bordered with a lighter colour, below the costal margin feebly though distinctly undulatingly dentate. The subterminal row of black spots is complete, arranged as in *prosper*; the blackish discal shadow is faint but broad, extending from the subbasal line to the subterminal line. Hindwing very dark, deeply coppery blackish-brown, with 3 lighter transverse bands: an antemedian, a postmedian, and a marginal one; the hind-margin exhibits hair of the same colour. Penis similar to that of *conradti*, but on the whole much stouter, shorter and broader, the main spine being shorter with a much broader base, the accessory spine rising higher, so that both apices are situate in the same height; the 11th tergite is quite different from *conradti*, but the differences of the penis are sufficient for the characterisation. According to several ♂♂ from Chiapas (Mexico), taken in June, named in honour of ROBERT MÜLLER in Mexico; type in the Coll. DRAUDT. — **guatemalteca** *f. n.* (78 e) is evidently a form of it, much lighter and more contrastingly coloured, particularly the whole marginal third conspicuously light; the intensely blackish-brown darkened median area is much broader, inside undulatingly, outside almost rectilinearly defined, with an obtuse angle on 7, the white discal dot stronger, situate within the median area, the black discal longitudinal patch sharply defined, only between 5 and 6, the postmedian border-line more distinct; hindwing also much lighter. According to a faultless ♂ from Guatemala in the Coll. BANG-HAAS.
- granula*. **P. granula** *Schs.* (= *hempsteadii* *Schs.*) (77 d, 86 a) is allied to *conradti*, but larger, with still broader wings, the median area broader, more blackish-brown, at the costal margin 1 cm broad, at the hind-margin only $\frac{1}{3}$ cm broad, the proximal border below the costal margin distally angular, the distal border hardly dentate, on the uppermost radial branch distally angular, from there extending in a flat, inwardly concave bow to the hind-margin; the discal longitudinal patch is distinctly defined, blackish, more distinct than in the two preceding species; the small subterminal spots are distinctly ochreous, either all, or only the anal ones, spotted black. Guatemala. This species was regarded by SCHAUS as a synonym to *conradti*, but according to what has been said at that species, this is probably not the case. The species varies besides in the lighter or darker, more yellowish or reddish ground-colour and in the width of the median area.
- crossaea*. **P. crossaea** *Drc.* (77 e) of which likewise only the type is known, which is besides so much damaged that but few details are yet to be recognised, is presumably also allied to *conradti*, but very much lighter, quite unicoloured light reddish-brown, behind the median area still lighter, the markings very indistinct, anally with two small black spots arranged as in *conradti*, farther above there are some more punctiform ones. The specimen is somewhat smaller, the apex of the forewing somewhat rounder, the distal margin more convex. Mr. TAMS kindly sent a photo of the type and a microphotographic reproduction of the genital organ; accordingly, the penis on the whole exhibits a much broader and shorter, almost flat wing-like shape and is not so deep dark brown chitinated, the vesical edge of the terminal spine shows in its upper half 2 smaller accessory spines, each of which is again provided with a still smaller accessory spine, so that this edge looks like a short blade of a saw; the opposite edge shows below the centre an intensely chitinated hunched projection. Bahías, Jalisco (Mexico).
- lemoulti*. **P. lemoulti** *Schs.* (77 e) forms a transition from *conradti* to *nox*; a very large species with narrower wings; forewing dark brown, thorax and hind-margin of forewing hued with grey, before the centre with 2 yellowish-red dentate lines, convergent to the hind-margin, also 2 postmedian finely waved lines which are dentate towards the costal margin; the light brown irregular subterminal row of spots exhibits the usual black centres. French Guiana. — **yahuarta** *Dogn.* (77 e) is somewhat smaller; the author considers it to be a local race of the preceding species. Peru (Yahuarmayo).
- negrita*. **P. negrita** *Dogn.* (78 c) is still somewhat smaller, on the dark yellowish-brown forewing the antemedian area, the transverse lines, and the subterminal area are lighter, the first line at the hind-margin farther from the base than at the costal margin; the small light subterminal spots with but one black anal dot. Hindwing coloured like forewing, with reddish-brown fringes. From the Rio Negro (East Colombia). Separable from *antonia* by waved transverse lines.
- nox*. **P. nox** (= *melana* *Dogn.*) (78 c) is very similar to the preceding species, large and strong, but much darker, with almost black hindwings and marginal area of the forewing; lines arranged exactly as in *lemoulti*. The type of *nox*, from the Coll. STAUDINGER, is not separable from *melana*, only the transverse lines are more indistinct owing to the insect having flown very much, but on examining the insect very carefully they show the very same course, the white discal dot being also present. A ♀ from the Berlin Museum is very large, with yellowish veins, all the subterminal spots very conspicuously rusty yellow. Panama to Colombia and Brazil. The penis exhibits a great resemblance to that of *conradti* and especially of *mülleri*.

7. Genus: **Edwardsimemna** *Neum. & Dyar.*

Distinguished by bare small eyes, a very short cell of the forewing, from the upper angle of which 7 and 8 rise on a joint stalk with 6. The basal loop of the hindwing is short, the distal margin somewhat undulating. The short palpi are straightly porrect, the abdomen does not project beyond the hindwing.

Type: *E. jalapae* *Edw.*

E. jalapae *Edw.* (78 d). Light reddish-brown, the hind-margin and marginal area lighter, more *jalapae*. violettish-grey, with a slightly darker border of the median area, the distal line towards the costal margin bordered with whitish; subterminal line somewhat more distinctly dentate. Thorax and abdomen greyer. Mexico.

8. Genus: **Dicogaster** *B. & McD.*

It has likewise bare though much larger and thicker eyes. The wings are shaped as in *Quadrina*, and also have the same veins except that 10 terminates into the apex, 9 below it into the distal margin.

Type: *D. coronada* *Barnes.*

D. coronada *Barnes* (78 d) has an exterior almost like that of *Q. diazoma*, where the differences are *coronada*. mentioned. In the type the red-brown forewing is densely intermixed with whitish grey, the white transverse lines are narrowly bordered with red-brown; the stréwing may be so dense that the wings almost appear grey. — f. **valens** *Dyar* is without any grey irroration at all, for which reason the white transverse lines on the deep *valens*. red-brown ground do not appear to be bordered with brown. The larva resembles that of the European *quercus*, being red-brown set with silky white hairs, with yellow stigmata. It lives on *Quercus arizonica*, hibernates almost in its adult stage, and pupates at the end of April in a loose blackish brown web. Arizona; recently also reported from Mexico (Michoacan).

9. Genus: **Mesera** *Wkr.*

This genus being extremely allied to the following I have nevertheless separated, because it forms a good connection of the large preceding genera and the following genus. From *Macromphalia* it differs in the shorter, not so long combed antennae and a small anal tuft in the ♀.

Type: *M. tristis* *Wkr.*

M. tristis *Wkr.* has remained unknown to me, the male with a red-brown body and black antennae has *tristis*. blackish-grey wings, the forewing is somewhat darker and more densely powdered than the hindwing. Length of forewing: 12 lines. Venezuela. The ♀ which, however, surely does not belong hereto, is described to be lighter, the forewing with an undulating grey band near the distal margin. Length of forewing: 19 lines. From Bogotá.

M. arpia *Schs.* (75 e) is in both sexes bright red-brown with a thick black roundish discal spot; *arpia*. in the ♀ the border of the median area projects twice distally and is distinctly prominent by a postmedian brightening, in the ♂ hardly distinct. Anal tuft of ♀ whitish. Brazil, Argentina.

M. crassipuncta *sp. n.* (75 e) has a somewhat obliquer distal margin of the forewing which is somewhat *crassipuncta*. lighter and not so bright red-brown; the ♂ exhibits a broad dark postmedian band projecting distally on 4 and 7; the round discal spot is still larger than in *arpia*. Described from a ♂ from Surinam. Type in the Berlin Museum.

M. rimicola *sp. n.* (75 e) is much smaller, monotonously light reddish-brown, with a small blackish *rimicola*. discal spot. Anal tuft light slate-coloured. Described from a ♀ from Buenos Ayres. Type in the Berlin Museum, a similar ♀ is in Washington in the National Museum.

10. Genus: **Omphalia** *H.-S.*

This genus must be kept separate, because in the two specimens that are in the Berlin Museum and were lying before me (among them the type) veins 7 and 8 of the hindwing are stalked as in the genus *Sphinta*; they rise only shortly before the cell-angle, in *Sphinta* near the base. Palpi somewhat longer than in *Macromphalia* with which the other marks correspond.

Type: *O. psorica* *H.-S.*

psorica. **O. psorica** H.-S. (75 f) is in the ♂ greyish-brown, the body somewhat lighter and more yellowish; on the forewing the median area is edged by 2 darker lines which are bordered with lighter on the averted sides, the distal line projecting twice distally in an acute angle; in each of the two cell-angles there is one black dot; the darker subterminal line being parallel to the distal margin is distally round waved between the veins and towards the distal margin bordered with a lighter colour. Type from Venezuela. The small whitish ♀ with narrow wings and a very large anal tuft, being figured by HERRICH-SCHÄFFER, certainly does not belong to this species, but is probably much rather a *Tolyte*.

11. Genus: **Macromphalia** Fldr.

Evidently very closely allied to the preceding genus, but at once discernible by the separate origins of veins 7 and 8 of the hindwing. The rudimentary palpi are somewhat drooping. They are, moreover, robust insects with broad wings, the ♂ with a relatively short abdomen, the ♀ without an anal tuft; ♂ antennae very long, with long pectinations. Costal margin of hindwing straight or somewhat concave. The range of most of the species extends into the southernmost parts of South America to Chile. Most of the Chilean species are very variable and seem to me to belong to but very few species. Examinations of the genitals are here absolutely necessary in order to ascertain which is a species and which a form.

Type: *M. chilensis* Fldr.

- lignosa*. **M. lignosa** Wkr. (75 f) is a very doubtful insect; according to SCHAU, there is in the Coll. DOGNIN as *lignosa* a *Macromphalia* which looks very much like the following and differs in the broader median area with a less dentate distal border which is bordered with broader and purer white; subterminal area not lighter, without the small black spots therein. From the common point of view, however, *lignosa* is an *Euglyphis* of the *narceta*-group (cf. there!). Argentina, Chile.
- chilensis*. **M. chilensis** Fldr. (75 f). Body and wings greyish-brown; mesothorax and base of abdomen darker; forewing with a darker median band, its dark border-lines on the averted sides lighter, the distal one projecting thrice distally acute-angled; postmedian area somewhat lighter, then follows a still lighter subterminal band on the outside of which there are small black internodal spots; in the darker marginal area the veins are somewhat lighter. Chile (Valdivia). — Larva greyish-brown with a double row of long black pencil-like brushes; head black with a yellow V-shaped marking. Ventral feet and claspers reddish.
- rubrogrisea*. **M. rubrogrisea** Phil. (= *rustica* Phil.) (75 f) is very similar, but the median area is broader, occasionally prominently darker, the light subterminal band is absent, the row of the small dark antemarginal spots is more coherent, the distal border of the median area is not so pointedly notched, between the veins roundish convex. Chile.
- valdiviensis*. **M. valdiviensis** Dogn. (75 f) has a somewhat lighter reddish-brown forewing with a dark brown median band which is twice as broad at the costal margin as at the hind-margin, enclosing a small black discal spot, and on both sides bordered with light, the distal border projecting still more flatly than in the two preceding species; fringes on the ends of the veins crossed by a somewhat lighter colour. Described from 1 ♂ from Valdivia.
- rivularis*. **M. rivularis** Btlr. (= *dedecora* Phil. nec Feisth.) (75 g). The ♂ is above greyer than the preceding species, the border of the median area is almost white, shaped as in *valdiviensis*, with a submarginal double row of small whitish lunae; the black median spot is strong. The ♀ is lighter, yellowish-white, the border of the median area represented by brown double lines, in the subterminal area before the black antemarginal lunae with a greyish-brown notched nebulous band; costal area in the centre and subapically darkened with brown. Chile.
- dedecora*. **M. dedecora** Feisth. (= *ancilla* Phil.) (75 g) is on the forewing greyish-brown, at the apex somewhat lighter, with 3 waved blackish-brown transverse lines and a black discal dot. Hindwing darker, with a whitish median band and darker subterminal band. Chile. — The larva is clothed with brown hair, with a double row of long black, pencil-shaped hair-tufts along the dorsum. Cocoon similar to that of *C. potato*. It lives on Pinus and Mühlenbeckia.
- purissima*. **M. purissima** Btlr. (75 g) is snow-white, in the basal half of the forewing, on the hindwing and body with a silky gloss; the median area of the forewing is edged by 2 brown lines, the proximal one consisting only of a costal-marginal streak, the distal one at the costal margin black and notched; a submarginal indistinct row of small black lunae, at the costal margin before them an oblong black spot, at the cell-end a black spot. Hindwing with a brown hair-pencil at the cell-end. The ♀ is more yellowish, with much fainter markings, the submarginal lunae combined as a fine brown line; hindwings with brown anal spots. Chile.
- hypoleuca*. **M. hypoleuca** Phil. (75 g) resembles *rivularis*, but it is lighter, the ♀ quite yellowish-white, the lines as fine as hairs, not double, but single. Hindwing without markings. Chile.
- affinis*. **M. affinis** Feisth. (75 g) resembles *purissima*, but in the ♂ the wings are chalky white, scantily strewn with brown, producing a grey impression. Lines arranged as in all the allied species. Chile (Valparaíso).

M. nitida Btlr. (75 g) is in the male dark copper-coloured, towards the margin lighter greyish-white, with two black transverse lines, the distal one almost double, on the averted side more or less brightened, especially at the costal margin; a subterminal row of small blackish-brown spots. Hindwing copper-coloured. The ♀ is whitish, strewn with black and grey, marked as in *dedecora*-♀, but the markings are more hazy, the colour darker. Chile. *nitida*.

M. catharina Dogn. (75 h) is on the forewing monotonously chestnut-brown; a waved subterminal line, not darker than the ground, is distinctly prominent by a double row of small feeble whitish lunae. Hindwing somewhat lighter red-brown. In the body a few whitish hairs are intermixed, frons whitish. Sa. Catharina. Described from a ♂. *catharina*.

M. spadix sp. n. (75 h) is similarly coloured, but with a discal spot and 2 black transverse lines, the distal line on 2, 4 and 7 distally angled as in *chilensis*; a subterminal line of black spots distally lighter by white scales, distal margin blackish before the fringe which is crossed by black. Hindwing without markings. According to a ♂ from Valdivia. Type in the Berlin Museum. *spadix*.

M. lojanensis Dogn. (79 a) initiates another small group of allied, somewhat more slender, grey species. Forewing whitish-grey, base, median area and marginal area darker, the median area edged by dark grey lines, with small indistinct discal spots; a subterminal row on the veins distally dentate, before it an indistinct curved nebulous line, behind it the margin is whitish; fringes on the veins crossed by light. Hindwing almost white with a brownish marginal line. Ecuador. *lojanensis*.

M. deficiens Dogn. (79 a) is more slender, with a longer abdomen, a much duller colouring and marking, the postmedian line more oblique, the antemarginal line quite indistinct. Hindwing not so white, at the hind-margin and anal angle very brown, with a very faint subterminal shadow. Colombia. *deficiens*.

M. canescens Dogn. (79 a) in contrast with *deficiens* is stronger, larger, much more clearly and distinctly marked, the median area narrower, edged by blackish-brown lines, costal margin darkened by blackish-brown, fringe speckled black and white, ground-colour of a purer ashy grey, hindwing pure white. Colombia. — **quindiensis** f. n. (79 a) is still much larger, the median band broader, more rectilinearly defined, fringe not speckled, hindwing at the hind-margin broad blackish. From the Quindiu Pass (FASSEL). Type in the Mus. Senckenberg. *canescens*. *quindiensis*.

12. Genus: **Norapidia** g. n.

The genus contains 2 *Lasiocampidae* described as *Norape* (*Megalopygidae*) by DOGNIN, allied to *Omphalia*. They are distinguished by a more pointed, in *divisata* almost falcate apex of the forewing and a longer, more slender abdomen; the middle joint of the longer palpi is flatly compressed, wing-shaped. The cell of the hindwing is very short, the cross-vein very oblique, 4 and 5 rise from the same place; on the forewing 9 and 10 terminate before the apex into the costal margin. Only 2 species:

Type: *N. divisata* Dogn.

N. divisata Dogn. (75 h). Forewing brown, in the basal $\frac{3}{4}$ much darker, with a purple reflection, towards the light brown terminal area feebly defined in an S-shape, the apex of this border terminates into the apex; an antemarginal row of small blackish internerval spots. Hindwing light brown. From the Quindiu Pass (Colombia). *divisata*.

N. subdelineata Dogn. (75 h) is larger than *divisata*, of a deeper purple brown, the marginal area hardly lighter, a submarginal curved row of white, black-centred spots, the 3 costal ones much larger than the others. Hindwing lighter red-brown. From Mt. Tolima (Colombia). *subdelineata*.

13. Genus: **Tolype** Hbn.

Palpi feebly developed, mostly bent downward, forewing rather long, but generally broader than in *Titya*, the distal margin of the hindwing straighter, the abdomen of the ♀ very strong with a thick anal tuft. On the forewing 6 and 7 are forked with 8, 9 and 10 rise on a very long stalk, generally bifurcating only right before the apex. On the hindwing 6 and 7 are distinctly separated, the cross-vein more or less angular, just like the lower cell-margin on 3, the upper one on 7; 9 entirely absent, basal loop very feebly developed. 4 and 5 rise from the same place, 3 rather far before them. Rather numerous large and small species, sexes mostly of very different size, colouring, and marking. The few larvae that are known generally resemble the palearctic *Taragama* which the genus resembles in many ways; they are mostly clad with short and thin hairs, between them with hair-tufts on knobbed tubercles, larger fleshy cones on the first ring, flanking the head on both sides, and mostly

with a torous decorative spot on the first ring. The genuine *Tolyte* being allied to the generic type *velleda* exhibit on the mesothorax very peculiar large spatulate or oar-shaped hairs of a blackish-brown colour with a more or less intense steel-blue reflection; in the *velleda*-group they occupy the whole length of the thorax, whereas in *brevicrista*, *mollifacta*, and *vemerila* they are only on the metathorax. In the *innocens*-group such long-stalked spatulate hairs are on the abdomen, most of the other *Tolyte* are without them. Whether according to these differences other genera are to be separated, cannot be decided at present.

Dr. HARRISON G. DYAR, Washington, had the kindness to characterise for us the very difficult North American forms of *Tolyte*, though, as he writes, without any very satisfactory result; for beside the great individual variability, it is at present impossible to say what constitutes a species and what a form. Thorough examinations, particularly of the genitals, are therefore here more necessary than in other genera, and the accurate division of this genus must be left to the future.

Type: *T. velleda* Stoll.

- velleda*. **T. velleda** Stoll is the oldest name of a group of allied forms in which the forewing is whitish with a broad blackish median and subterminal band both of which are more or less crossed by white veins and accompanied by more or less distinct narrower linear stripes. — **velleda** Stoll (81 a) is the largest species of the eastern U. S., both sexes similar; thorax white, markings of forewing shaded, the dark colour grey, extensive, so that the forewing seems grey marked with white lines. Larva brown with darker longitudinal lines and a bluish-black decorative spot on the 3rd ring, it lives on oak and changes into an obtuse brown pupa in a long yellow web. As long as so little is known about the different forms, we prefer quoting them in the usual way as species.
- mint*a. **T. mint**a Dyar (81 a) is very similar to *velleda*, but smaller and from Florida. Perhaps only a southern race of *velleda*.
- glenwoodi*. **T. glenwoodi** Barnes (81 a) is likewise smaller than *velleda*, the markings darker and more sharply cut, the median grey space of the forewing generally narrower. From Colorado and New Mexico.
- dayi*. **T. dayi** Blackmore is hardly discernible from *glenwoodi* and may be only a local form of the same species. From British Colombia.
- lowriei*. **T. lowriei** B. & McD. (81 a) is very similar to *glenwoodi* and perhaps a race of it from California. The ♂ is whiter than most *glenwoodi*, more like the ♀ which has no tangible differences from *glenwoodi*-♀. Compared with *mint*a it is larger, the distal border of the median band more regular. The larva is greyish-brown, in the black decorative spot there are 2 yellow dots; on the dorsum darker spots. It lives on Abies.
- laricis*. **T. laricis** Fitch (= *minuta* Grt.) (81 b). The ♂ is black, the ♀ white, the ♂ very black and with only traces of pale lines on the wings, the ♀ similar to that of *velleda*, but separable by much smaller size, whiter abdomen and often a broad white space in middle of forewing. Atlantic States.
- distincta*. **T. distincta** French (81 b). Thorax dark grey in the ♂, pale grey in the ♀; veins of forewing rather distinctly white, a pale grey over the surface in the ♂, crossed by narrow white lines and two dark grey lines, one beyond the inner line, the other after the double whitish outer lines. From Colorado, with *glenwoodi*, but apparently a distinct species.
- tolteca*. **T. tolteca** Neum. (= *deboma* Drc., *hemira* Drc.) (79 a) is the Mexican representative of the *velleda*-group, generally greyer with darkened hindwings, the curved subterminal band distinctly darker than the hardly darkened median band; on the whole extremely variable in the white or rather grey ground-colour, the thorax also in the greyer specimens always conspicuously white. DYAR writes that he cannot see how it is to be separated from *glenwoodi* and also from *hemira*, so that they are probably synonyms.
- dyari*. **T. dyari** sp. n. Draudt (81 b) is apparently a well defined rather invariable species which hitherto came only from Zacualpan in Mexico. Ground-colour brownish grey, not white, also the thorax and abdomen greyish-brown, median and subterminal areas narrower, both equally dark, the border-lines much less curved, particularly the inner one of the subterminal band almost straight and somewhat faded, not distinct; hindwing dark greyish-brown. Described from several ♀♀; type in the Coll. DRAUDT.
- brevicrista*. **T. brevicrista** Dyar (81 b) is the typical representative of the second group, in which the dark spatulate hairs are only on the metathorax as in the two following species. On the forewing the white predominates, the dark marks not heavy. New Mexico.
- vemerila*. **T. vemerila** Dyar (79 b, e). Forewing very light grey, almost white, crossed by grey lines which are traversed by the white veins, both the lines bordering on the not darkened median area are double, irregularly waved, the subterminal line more spot-shaped. Hindwing shaded with grey, veins darker. Mexico (Guerrero, Tehuacan).
- mollifacta*. **T. mollifacta** Dyar (79 b) is darker grey, the light markings of the *velleda*-group very feebly marked, with a white line at the base of the fringes on both wings. Mexico (Colima), taken in January.

T. salvadora Dogn. (81 b) is somewhat similar to *velleda*, greyish-white, the median band hardly *salvadora*. darker, the proximal border almost straight, the distal border oblique, distally angular; in the interior traversed by 2 more, partly hazy lines; there are 2 more subterminal and antemarginal bands divided into oblong grey spots. Hindwing greyish-white. Wings somewhat opalescent. San Salvador.

T. abdan Schs. (81 c). The white forewings are scantily sealed, the darker lines very feeble, the two *abdan*. median ones proceeding from square brownish costal-marginal spots, the postmedian line reduced to short vein-streaks. Subterminal line cinnamon reddish, below the apex distally removed and widened as far as 6, also between 4 and 3, otherwise narrow; cross-vein white sealed, at the apex with 3 dark dots. Hindwing smoky blackish, in the disc whitish, with a narrow white subterminal band. In this species the cell of the hindwing is very short, so that vein 6 rises from 7 near the base. Panama *).

T. dollia Dyar (81 e) is an almost unmarked pure white species, with but 2 or 3 small black spots *dollia*. at the costal margin, the subapical one of which is largest, from the latter a subterminal row of diminutive black vein-dots crosses the wing, and a similar dot is at the base of vein 2. The species recalls a *Norape*. Mexico (Colima).

T. adolla Dyar (79 b) is allied with the following species, but the median lines are straighter, *adolla*. darker, and more distantly separated. Forewing white with a broad light grey subbasal line, both the median lines crossed by the white veins, the subterminal line broad, faded grey. Mexico (Misantla).

T. albula Drc. (81 e) resembles *adolla*; forewing and hindwing white, the grey bands somewhat *albula*. broader, less straight, and the two median ones more closely together. Fringes of both wings white. Mexico, Coatepeque.

T. mota Dyar is likewise very closely allied to *albula*, but of a stronger structure with a longer *mota*. abdomen, the lines as in *albula*, but darker, particularly in the costal-marginal third, the median lines somewhat more separated. Likewise described from Coatepeque (Mexico).

T. lasthenioides Dogn. The ground-colour is slightly more yellowish-white, the undulate lines reddish- *lasthenioides*. brown, partly somewhat faded, the veins upon them partly marked with a darker brown, the postmedian line being broadest and apparently composed of several lines, with 3 black small angular spots between 1 and 2, 3 and 4, 7 and 8; cross-vein white with a black dot in the upper cell-angle. Fringe between the veins speckled with red-brown. Hindwing yellowish-white. South-Eastern Peru.

T. nigribarbata Dogn. (79 b) resembles *lasthenioides*, ground-colour yellowish-white, markings rusty *nigribarbata*. red, forming 3 incomplete macular bands, with a row of diminutive costal-marginal spots in the distal two thirds: in the upper and lower cell-angles one black dot each. — f. **nigricula** Dogn. differs from the nomenclatural type *nigricula*. in more blackish macular bands, also the fringe between the light veins being more or less blackened, in *nigribarbata* all white. Both forms from South-Eastern Peru. Only ♂♂ are known.

T. nuera Dogn. (81 e) was described as *Artace*. Forewing greyish-white, at the distal margin of a *nuera*. purer white, with traces of grey antemedian and postmedian lines, and a small black discal dot. Fringe dingy white, at the apex more grey. Hindwing dull white. Body white, at the abdominal end with black hairs. Loja (Ecuador).

T. flexivia Dogn. (81 e). Forewing yellowish ochreous, in places mixed with reddish-brown, the lines *flexivia*. indistinct and faded, the postmedian area strewn with blackish between 7 and the costal margin, 3 and 4, 1 and the interior margin; in the upper cell-angle with a black dot; subterminal line light; at the apex a black spot, extending to the base of the fringe. Hindwing light yellowish ochreous. Peru.

T. cinella Schs. (79 f). Head and body are light brown, collar and thorax white. Forewing yellowish- *cinella*. red, in the basal third and subterminally strewn with blackish; subbasal line dark grey, the two median lines brown, the posterior line angular below the costal margin, then undulating to the hind-margin; at the base of vein 6 there is a black dot; subterminal lines double, black, behind it a white broad undulating marginal line. Hindwing light brown with a broad grey subterminal shadow. Castro, Paraná, Brazil.

T. gelima Schs. (81 e). Body and forewing yellowish-reddish, abdomen with brown bands; veins 2, 3, *gelima*. and 4 are black as far as the subterminal line, behind it all the veins are whitish; the brown median lines as in *cinella*, but less distinct, a postmedian brown area, the apex darkened by grey; between 5 and 6 there is a brown spot at the distal margin. Hindwing brown, darkened towards the lighter distal margin. Castro, Paraná, Brazil.

T. miscella Dogn. (81 e). Body yellowish-white, with an olive tint on the abdominal dorsum. Forewing *miscella*. olive grey mixed with white, before the centre and subterminally and terminally strewn with black, the two indistinct median lines white, the postmedian one inserted between 2 and 3; cross-vein white with a black dot in the upper cell-angle; subterminal line white, forming bows between 2 and 3, and 4 and 6, at the apex bordering on a black spot; fringes blackish. Hindwing blackish with white ends of the fringes. Muzo (Colombia).

T. medialis Jones (= *flavobrunnea* Dogn.) (79 b) is very variable in the size and distinctness of *medialis*. the marking. Head, collar, and patagia are of a bright rusty brown like the abdominal dorsum; mesothorax,

*) On account of the short cell of the hindwing better to be placed to *Titya*, near *alma*.

sides of abdomen, and anal end with blackish and greyish-brown hairs. The yellowish-brown forewing with a more or less reddish tint exhibits a dull blackish, not distinctly defined median band which is very broad and light brownish in the centre here, in front of it and behind it several darker yellowish-brown undulating lines; subterminal line light, before and behind it at the apex blackish powdering, sharply crossed by the light veins. The much smaller ♂ is much darker blackish brown, thorax and abdomen contrastingly fox-coloured, the median area above 2 still darker, containing the whitish cross-vein streak. Widely distributed and common in Brazil. In more greyish-brown specimens the thorax and abdomen are not rusty brown, but of the same colour.

hella. **T. hella** H. S. (= *vocontia Drc.*) (79 c) is much more allied to *medialis* than it might appear from the first glance. Forewing reddish yellowish-brown, in the marginal area with distinct and fine white veins, very similarly marked as *medialis*, but the lines and the median band but slightly darker than the ground; the median vein is likewise fine white, at the cell-end there is a whitish transverse streak; apex blackened. The ♂ is relatively large, with broad and round wings, coloured and marked like the ♀, but generally behind the subterminal line somewhat darkened by blackish-brown. Widely distributed and common in Brazil.

regina. **T. regina** Dogn. (81 c) has the same scheme of markings as the preceding species, but the ground-colour is blackish-grey („pepper and salt“), with light flesh-coloured median area and transverse lines, the latter bordered with olive, the marginal area likewise olive; at the cell-end above and below one dark olive dot each. Hindwing flesh-coloured reddish-grey, subterminally blackened, the margin and fringe olive. Described from a ♀ from French Guiana.

dulcis. **T. dulcis** sp. n. (Maass. i. l.) (79 c) is very similar to *medialis*, light yellowish-brown like the thorax and abdomen, the latter with a thick greyish-black anal tuft. Lines much more sharply dentate, the postmedian line with dark vein-dots on the tips; median area not scantily scaled, blackish, but brown, edged by 2 dark dentate lines; in the middle at the costal margin not lighter; the subterminal line forming in *medialis* small crescents distally projecting between the veins, forms here only 3 large flat bows, and the marginal area behind it is not darkened. Hindwing lighter. Described from a ♀ of an unknown habitat, in the Berlin Museum (in Coll. MAASS).

catharina. **T. catharina** sp. n. (79 c). Head, thorax, and abdomen light ochreous, the lines being similarly bordered as in *dulcis* and the median area more prominently dark yellowish-brown, very undulatingly dentate, the median area distally projecting on 7 in an acute angle, above it as far as the costal margin with 3 pointed small dents; a subapical large brown crescentiform spot embraced by the branches of the white subterminal line which is only subapically visible. Fringe broadly speckled with whitish. Hindwing light yellowish-red. Described from a ♀ from Sa. Catharina, in the Coll. WERNICKE. The ♂ is much more distinctly marked.

sorex. **T. sorex** sp. n. (79 c) is similar to *catharina*, but with much broader wings, the colouring is much lighter, whitish, in the basal, median, and marginal areas not darker, crossed by about 7 notched light rusty brownish transverse lines; in the basal quarter of the costal margin and apically strewn with blackish. Hindwing almost white. Abdomen yellowish-white, only dorsally and at the anus with rusty brownish hairs like the thorax. Remarkable by particularly long, tapering palpi. According to 1 ♀, habitat unknown, in the Berlin Museum.

pelochroa. **T. pelochroa** Berg is unknown to me, in the colouring and organisation described as allied to *hella*, with the same wing-contours and scheme of marking on the forewing; median area filled with a darker colour excepting the costal margin, undulating line indistinct, only in the dark apex more distinct; margin dark excepting the ends of the veins. Ground-colour ochreous; the postmedian line forms 3 or 4 bows. Base and marginal line of hindwing somewhat lighter. Expanse of wings: 52 mm. Rio de Janeiro. The description is rather similar to that of *medialis*.

innocens. **T. innocens** Burm. (79 d). As to the identification of this species and the following I am not certain, though I consider the couple denoted as *innocens* in the Berlin Museum, from Buenos Ayes, to be correct. Greyish brown, lines arranged as in *hella*, median area edged by 2 more intense lines, with 2 black discal dots; apex blackened, the darkest, before the subterminal line. The ♂ is lighter, more yellowish, scantily scaled, the transverse lines edging the median area are distinct, the lower discal dot is mostly absent. Abdomen much more intensely haired rust-brown. Larva dark brown or grey, finely striated with reddish-yellow, with large bluish-grey tubercles margined with red or yellow with black spines, the brownish-grey lateral hairs as much as 1 cm long, among them on the 4th and 11th segments with black lustrous spatulate hairs. It lives on *Schinus molle* and *Duvana dependens*, and constructs a flat yellowish-grey cocoon on the twigs. Brazil and Argentina.

pauperata. **T. pauperata** Burm. (79 d) is very similar, the lines of the median area feebler, in the ♀ the inner line almost quite absent; in the median area there are below the cell two chestnut-brown round spots, the lower of which is mostly more indistinct; the lower discal dot is usually absent; subapically broad blackish irroration. The ♂♂ are lighter or darker, mostly more yellowish. Brazil, Argentina. Larva, according to BERG, on *Acacia* and *Celtis tala*, similar to *innocens*, with 2 long lateral hair-pencils. Cocoon of a dingy yellowish grey.

pellita. **T. pellita** sp. n. (79 d) is allied to *innocens* and *pauperata*, but much larger, yellowish-brown, the lines are lighter wavy lines, only those enclosing the not darkened median area are more brownish, on the opposite sides bordered with light; in the upper cell-angle there is a thick black dot, in the lower angle a very fine

one, below the cell between 2 and 4 there are 2 small roundish chestnut-coloured spots, the lower of which is indistinct; apex from 8 to the costal margin blackened with whitish hairs, crossed by the undulating line. Hindwing lighter yellowish-grey with 2 blackish shadowy antemedian and postmedian bands. Long black spatulate hairs project from the brownish hair of the abdomen. According to 2 ♀♀ from Curitiba (Parana), type in the Coll. B.-HAAS. — *oculata* f. n. (79 d) is a specimen probably belonging to it, in the Berlin Museum, *oculata*. habitat labelled „Brazil“. It exhibits a somewhat more greyish-brown ground-colour, with the same scheme of markings, but only the much brighter rusty red spot between 3 and 4 is present, not round but quadrangular and below and outwardly bordered with jet-black.

T. biapicata Dogn. (81 d). ♂ on the forewing rusty yellow with a very large chocolate-brown discal *biapicata*. spot containing the white cross-vein streak, touching neither the costal nor inner margin, forming two projections outside on 4 and 6; subterminal line lighter, fringe on the veins crossed by light, with two black spots at the apex and between 8 and 9; hindwing rusty yellow with a broad lighter median band. The larger ♀ is pale the discal spot only indicated by brownish irroration ochreous, without any distinct border; subapically, before the subterminal line, brown irroration, the two small apical spots on the fringe are less distinct. French Guiana.

T. disciplaga sp. n. (79 d) is allied to *biapicata*, ground-colour pale ochreous brownish with a large *disciplaga*. blackish-brown discal spot distally projecting on 4 and 6 with 2 long dents, and containing the white cross-vein streak which reaches upwards only to the subcosta, whilst below it does not cross vein 2; the light subterminal line forming 3 large bows is inwardly bordered with grey and subapically with a darker colour; fringe speckled somewhat darker, apically rather darker, though the 2 black spots being very distinct in *biapicata* are absent here. Hindwing darkened by greyish-black with light ochreous fringe. Described from a ♂ without the habitat being stated, in the Berlin Museum.

T. albiapicata Schs. (79 c) is similar to the *innocens*-group. In the ♂ the ground-colour is reddish- *albiapicata*. brown, the darkened median area with a black dot in the upper cell-angle, the light subterminal line turns white in the apex which is blackened as in the preceding species. The larger ♀ is more reddish-brown, the apex very broad black, the subterminal line in it white; below the cell, as in *oculata*, a square chestnut-red spot, outside and below bordered with black; in the lower cell-angle there is mostly also a black dot. Hindwing greyish-brown with yellowish-brown fringe. Brazil (Novo Friburgo, Sa. Catharina).

T. viuda Schs. (= *fumosa* Giac. nec Dogn.) (79 e) belongs yet to the same group, but it is smaller *viuda*. and of a grey ground-colour. Below the cell with 2 small brown spots in the ♀, which are absent in the ♂, but neither seem to be always present in the ♀. Argentina (La Rioja, Formosa).

T. alegra Dogn. (79 e). The ♂ resembles that of *medialis*, but it is still darker blackish-brown, with *alegra*. distinct light veins, instead of the white cross-vein streak with a black lunule, at the apex mixed with whitish. The body is less bright rusty yellow, more dull red-brown. Brazil.

T. nana Drc. (79 e) is a widely distributed and common species; very similarly marked as the *nana*. preceding ones, but whitish, more or less mixed with grey or yellowish, with the same arrangement of lines as in *innocens*, the median area below the cell in the ♀ brownish black, between 2 and 4 filled with a more or less bright rusty yellow or rusty red colour, the apex in both sexes powdered with greyish-black, traversed by the distinct light veins and by the undulate line being white here. In the scantily scaled light ♂ the whole marginal area below 8 is more or less unmarked whitish; at the cross-vein there are 2 fine black dots. From Mexico through the whole of Central America. In the Berlin Museum there are in the Coll. STAUDINGER a few very old male specimens labelled: „*silveria* Cr.“; it may be that this name which cannot be identified any more is synonymous with *nana*.

T. perplexa Schs. (79 b) is very similar in the ♀, with broader and rounder wings of a grey ground- *perplexa*. colour, the median area not so oblique, but more vertically placed, the dark discal spot penetrates into the cell, distally projecting with a step below the median vein. The ♂ is much darker than that of *nana*, powdered with brown instead of light grey. Costa Rica to Colombia.

T. picta Fldr. (81 d) is another species extremely similar to *perplexa*; according to the figure the *picta*. brown median area extends as a broad brown postmedian line in a bow around the cell to the costal margin, behind it there are between the inner margin and vein 5 four intense blackish-brown spots; the violettish-grey postmedian area contrasts with the reddish-yellow marginal area, both colours being separated by the curved light subterminal line.

T. phyllius Drc. (81 c) is very similar to *nana*; only the ♂ has been described; instead of the yellowish- *phyllius*. white ground colour in *nana* only the base, inner margin, and marginal area of the forewing are of that colour, whilst the rest is suffused with blackish-grey, the lines as in *nana*. Described from Mexico (Guadalajara).

T. bipunctata Giac. (79 f) is closely allied with *viuda*, but the ground-colour of the ♀ is light Isabel- *bipunctata*. coloured, the lines are very feebly darker, less undulating, without discal dots, the 2 spots below the median are diminutive, blackish; the apex very little darkened. Body and hindwing reddish yellowish-white. Argentina.

- poggia*. **T. poggia** Schs. (81 d) is the first of a group of similar smaller species. In the ♂ the body is reddish yellowish-white; the forewing is greyish white, basally shaded with light brown, at the cross-vein there are 2 black dots; veins in the marginal half finely marked with brown; a postmedian waved grey shadow, as well as in the usual way at the apex; between 5 and 6 at the margin a grey spot, marginal line white, the brown fringe at the ends of the veins crossed by white. Hindwing light smoky brown, in the disc and the centre of the distal margin whitish. The ♀ is more grey, the abdomen above brown; on the reddish yellowish-white forewing there is in and below the cell a dark brown spot shaped as in *perplexa*; behind the white postmedian line follows a brown shadow towards the margin bordered with dark grey, the white subterminal area is shaded with grey towards the base. Expanse of wings: ♂ 24, ♀ 34 mm. Guiana.
- praepoggia*. **T. praepoggia** Dogn. (81 d) is still smaller; only the male is known. Forewing yellowish-white, the median area defined by 2 rusty yellow lines united above the hind-margin like spots, before and behind them indistinctly defined blackish transverse bands, the distal band projecting outwards in 2 bows; 2 black cross-vein dots; marginal area strewn with blackish, the broadest at the apex and between 4 and 6; the black fringe on the veins crossed by white. Hindwing yellowish-white, in the hindmarginal half and subterminally strewn with black. Colombia.
- meridensis*. **T. meridensis** Dogn. is larger than *poggia*, but very similar to it. Forewing greyish-white with a black dot at the upper end of the white cross-vein, the median area edged by two brownish faded lines, the postmedian line corkscrew-shaped; the brown fringe crossed by white. Hindwing white with two brown spots, an apical one and a postmedian one between 3 and 5. From Venezuela (Merida), described from 1 ♂.
- fasciatus*. **T. fasciatus** Drc. has remained unknown to me. Body and wings white, abdomen at the end yellowish brown. The white forewing in the basal area and at the apex powdered with black; the white hindwing is crossed by a blackish demi-band from the apex. Expanse of wings: 1 inch. Carabaya (Peru).
- lemoulti*. **T. lemoulti** Schs. Only the ♀ is known. Body brownish ochreous, abdomen above blackish-grey. Forewing brownish ochreous, with darker veins, at the apex in the usual way powdered with dark grey; the distal margin is narrow brown, between 5 and 6 broader, at the cell-end there is a black dot; 2 hardly darker antemedian transverse lines are very indistinct, 3 dentate postmedian ones similar, the last outside below 4 shaded with dark grey; subterminal area Isabel-coloured, traversed by an indistinct darker line. The yellowish hindwing is powdered with ochreous at the hind-margin and exhibits a brown marginal line. Expanse of wings: 36 mm. French Guiana.
- ferrugo*. **T. ferrugo** sp. n. (79 d) is a small species allied to *innocens*. Forewing and body reddish-yellow, the latter mixed with rusty red; forewing finely veined black with 2 black cellular dots; transverse lines darker, running as in *innocens*, apically the subterminal line is powdered with black; fringe feebly speckled darker. Hindwing somewhat lighter, more yellowish-white. Described from a ♂ from Buenos Ayres; type in the Coll. WEYMER in the Berlin Museum.
- adventitia*. **T. adventitia** sp. n. (79 f) is almost exactly marked like *ferrugo*, but much larger, and excepting the whitish serpentine subterminal band, of a grey ground-colour, the lines still darker grey, the apex in the usual way powdered with a still darker grey, traversed by the veins which are white here and besides finely marked with black. Hindwing grey with a narrow brownish marginal band. Body light brownish, abdomen above blackish, anal tuft darkest. According to 1 ♂ from Chaco (Bolivia); type in the Berlin Museum.
- effesa*. **T. effesa** sp. n. (79 f). Body Isabel-coloured brownish, abdomen with a greyish-black anal tuft. Forewing-white, in the basal area feebly brownish and strewn with grey, with a faded brownish antemedian line, taperingly projecting distally on 4; at the upper end of the cross-vein there is a black dot; the faded brownish postmedian line is broadest at the costal margin, projecting far distally between 8 and 9, and disappearing between 3 and 4; behind it there follows a light grey narrow band of a similar shape as in the two preceding species, behind it the whitish subterminal band as in *adventitia*; apex grey, the very narrow brownish marginal area projects inwards between 4 and 6. Base of fringe between the veins with feeble blackish strigae. Hindwing yellowish-white, at the anal margin somewhat brownish. Described from 1 ♂ from Pacho, Colombia. Type in the Berlin Museum.
- denormata*. **T. denormata** sp. n. (79 f) is an intermediate form between the preceding group and the *nana*-group. Body very light ochreous, abdomen analwards reddish-brown. Forewing light ochreous, in the marginal area more whitish; basal and median areas brownish, the latter edged by somewhat darker lines, the posterior one of which turns blackish between 6 and the inner margin; in the upper cell-angle there is a black dot; veins 2, 3, and 4, and the portion of the median vein between them are fine black as in *effesa*; behind the postmedian line there follows a double undulating line the inner portion of which between 6 and the inner margin is blackish, the exterior portion and that between 3 and 5 as a fine demi-bow; the marginal area behind it is very light between the anal angle and 7, marked with a hardly darker brownish, from 7 to the costal margin brownish, between 8 and the apex with 3 small black strigae extended into the fringe. Hindwing yellowish-white, fringe apically brownish. Described from 1 ♂ in the Berlin Museum, habitat unknown.

T. tenebrosa Wkr. (79 f) is somewhat similar to *alegra*, darker blackish-brown, particularly the body *tenebrosa*. not contrastingly lighter; forewing not with lighter veins, the median area hued with a deep chestnut-brown, the somewhat lighter cross-vein streak is edged by 2 darker parallel lines; apex as in *alegra* also strewn somewhat with white. Brazil.

T. nebulosa Schs. (81 d). Head and anterior half of collar brown, the latter behind and the patagia *nebulosa*. white, strewn with brown; rest of body brown, ventrum grey. Wings greyish-white, distal half of costal margin dark grey, in the upper cell-angle a black dot; 2 antemedian and 3 postmedian undulating grey lines, behind them a grey marginal shadow. Hindwing at the anal margin and distal margin from 4 to the anal angle powdered with dark grey. Expanse of wings: 33 mm. French Guiana.

T. nigra Dogn. (79 f). This and the following species are very closely allied, both being blackish- *nigra*. brown, with deeper black veins, and a black cross-vein streak; in *nigra* there is only a subterminal row of black internerval streaks, in front of which, towards the base, the ground is somewhat lighter grey except between 5 and 6. Peru, Colombia.

T. interstriata Dogn. is extremely similar to *nigra*, somewhat smaller, with somewhat broader wings; *interstriata*. it chiefly differs in the presence of a second postmedian row of black internerval streaks, the whole marginal area being lighter grey. Guiana.

T. iridescens Wkr. (79 g) is a larger species, with a white thorax and forewing, the latter being *iridescens*. scantily scaled with a greyish-brown base and median band, before and behind the latter with a grey transverse line, the distal one of which projects taperingly on 4, more obtusely between 7 and 8, behind it a subterminal band being broadly confluent with the median area at the costal margin, the area behind it as far as the narrow grey distal margin is white; at the distal margin black internerval streaks. Hindwing powdered with grey, with two darker, broadly washed out nebulous bands. Abdomen with blackish-brown ringlets. Costa Rica to Colombia and Brazil.

T. celeste Dyar (79 g) entirely resembles *Titya infernalis*, but the species is smaller, neater, with *celeste*. purer white forewings, the postmedian and subterminal transverse markings are less sinuate, the hindwings almost pure white. Only known from Mexico (Misantla, Tabasco, Colima).

T. caieta Drc. (= *nigropatagiata* Dogn.) is larger than *celeste*, of a purer white, with narrower transverse *caieta*. markings, the discal dot thicker, at the anal angle of the hindwing a dark spot. The ♂ is similar to that of *tolteca*, but easily separable by the thick black discal spot and the much more sinuate transverse markings and much whiter hindwings. Panama, Guiana, Colombia.

T. aroana Schs. has an exterior quite similar to the *primitiva*-group of the genus *Titya*. Body *aroana*. and wings dark grey, patagia yellowish pink. On the forewing the veins are striped ochreous, the cross-vein is black; 2 antemedian and postmedian whitish undulating lines each, being almost contiguous on vein 2; the broad subterminal band is likewise whitish; distal margin and fringes light grey with dark spots. Hindwing dark smoky grey. Expanse of wings: 34 mm. Only the ♂ is known. From Aroa (Venezuela).

T. columbiana Schs. (79 g) is larger, with broader and rounder wings, the inner margin almost as *columbiana*. long as the costal margin, patagia not much lighter, only somewhat intermixed with Isabel-colour; the broad median area is somewhat darkened, the light transverse lines feebly yellowish pink, the light grey subterminal area towards the margin dentate. Expanse of wings: ♂ 37. ♀ 44 mm. Colombia.

T. peruviana Dogn. is above extremely similar to *columbiana*; it appears to be somewhat larger *peruviana*. on an average, lighter, greyish-white, without the slight pink tint. Beneath very different from the more monotonous grey under surface of *columbiana*; forewing in the basal half blackish, at the costal margin as far as $\frac{2}{3}$ widened, and towards the greyish-white marginal area defined by a black, submedianly incurved line, at the costal margin with a dark subterminal spot. South-East Peru.

T. tarudina sp. n. (79 g) differs from the very similar *columbiana* in its more slender structure, *tarudina*. narrower forewings with a more oblique, longer distal margin and therefore much shorter inner margin. Head, collar, and patagia are more contrastingly whitish; forewing lighter grey, with softer and less contrasting markings, the median band obliquer, outside without the two projections, between 3 and 5 only very feebly convex, the parallel lines accompanying the median area outside and inside are almost quite absent. Hindwing relatively smaller, abdomen longer. Colombia; type in the Berlin Museum (Coll. STAUDINGER).

T. obscura Dogn. is compared with *velleda* in the structure. Body and forewing blackish-brown, *obscura*. forewing with a black cross-vein and traces of 4 whitish transverse lines, an antemedian one close in front of the cross-vein, the second close behind it, uniting with the first submedianly; the third is postmedian in the third quarter with the usual two convexities between 8 and 6, and below 4; the subterminal line is sinuate as

in *velleda*. Hindwing more brownish, feebly lighter postmedianly and a narrow brightening at the distal margin. Expanse of wings: 46 mm. Rio Songo (Bolivia). Only the ♂ is known.

guentheri. **T. guentheri** Berg (= *candida* Dogn.) (79 g, h) is the first of quite a different group of species. Forewing monotonously yellowish-white with a feeble reddish tint, the ♂ of a somewhat deeper colour; veins and fringes as well as a narrow discal spot somewhat darker; the anal tuft of the ♀ is black with a bronze-brown reflection. Argentina.

magnidiscata. **T. magnidiscata** Dogn. (81 d) is mouse-coloured with a very thick black cross-vein streak and a subterminal row of dark grey internerval spots, the one between 5 and 6 being less distinct, that between 8 and 9 forming a shadow; veins distinct dark. Hindwing basally and subterminally darkened. Only the ♀ is known. Expanse of wings: 59 to 63 mm. Peru.

villanea. **T. villanea** Dogn. (81 d) is allied to *magnidiscata*, but smaller. Forewing mouse-coloured, with fine and distinct dark veins, with two light, undulatingly dentate transverse lines; the posterior line extends from the second third of the costal margin, almost parallel with the distal margin, and terminates at the inner margin close at the antemedian line; at the cell-end a thick black streak. Colombia.

fumosa. **T. fumosa** Dogn. (79 h), described from a ♂ from Peru, is above monotonously brownish-black, with a thick black discal dot and three whitish transverse bands: a very short faded one close before the cellular dot, another one from the 3rd quarter of the costal margin to the centre of the inner margin, feebly incurved in the centre; the marginal line, finally, is connected with the postmedian line at the costal margin and extends narrower to the anal angle. Hindwing with a narrow whitish marginal band fading away before the anal angle. Body covered with long smoky-grey hairs. Expanse of wings: 34 mm.

incerta. **T. incerta** Dogn. (79 h). Forewing light loam-coloured with a small darker cellular dot and feebly darker, light-edged transverse lines, hindwing with a hardly visible lighter postmedian line. Body somewhat more yellowish. Only the ♂♂ are known. Argentina, also from Catamarca (Peru).

undulosa. **T. undulosa** Wkr. (79 h) is a scantily scaled, greyish-black species, marked as the following species, the median band not prominently darker, the discal spot indistinct, darker. Thorax darker; abdomen, particularly in the ♀, somewhat lighter grey, anal tuft black with a feeble bluish-grey reflection. Southern Brazil.

fuscicaudata. **T. fuscicaudata** Schs. (79 h) exhibits a somewhat purer greyish-black tint on the wings, the median area is more prominently dark, the light bands bordering on it are broad; abdomen with a brown tint, anal tuft deep black. Rio Grande do Sul.

vespertilio. **T. vespertilio** sp. n. (80 a) is similar, with somewhat narrower wings, the costal margin towards the apex more convex. The colour is a darker scpia-brown, the median band at the costal margin much broader, the edging narrow and only somewhat lighter, the distal one is distally bordered by a darker line. Abdomen coloured like the wings, anal tuft of a dull sooty black. The ♂ has broad wings and is somewhat browner, the fringes are crossed on the veins by a feebly lighter colour. Type from Rio Grande do Sul in the Coll. WERNICKE, Dresden.

pulla. **T. pulla** sp. n. (80 a) has broader wings than *vespertilio*, the somewhat darker median band proximally confluent with the likewise darker basal area without a light border, the distal third of the wing somewhat lighter; the discal spot is smaller and more distinct than in *undulosa*, the anal tuft deeper black. A slight concavity of the distal margin below the apex. Southern Brazil. Type: 1 ♀ in the Berlin Museum.

egena. **T. egena** sp. n. (80 a) is very similar to *undulosa*, only half its size, much paler and more brownish, the discal spot strigiform, the two light median bands broader than in *undulosa*, the subterminal band hardly sinuate, almost parallel with the distal margin. Anal tuft brownish-black. Type in the Berlin Museum, 1 ♀, patria not mentioned.

mediocris. **T. mediocris** sp. n. (80 a) is larger than *egena*, with somewhat broader and rounder wings, more blackish, the light postmedian band narrow, though distinctly prominent and submedianly more convex; the thorax is of a decidedly reddish-brown tint, the anal tuft is coloured like the brownish-grey abdomen. Type in the Coll. WERNICKE, Dresden, 1 ♀ from Sa. Catharina, other specimens are from Southern Brazil.

indecisa. **T. indecisa** Wkr. (80 a) is the lightest species of all its allies, particularly in the male almost white, also the median area being inside lighter whitish, the discal spot adjacent to the proximal line, deep black, almost quadrangular. Brazil.

ventriosa. **T. ventriosa** sp. n. (80 b) is somewhat similar to *indecisa*, but the colour is yellowish-brown in the ♀, darker brown in the ♂ which presumably belongs to it; marking as in *indecisa*, the median band in the ♂ filled with dark brown; fringes slightly speckled by light interruption on the ends of the veins. Abdomen of ♀ reddish-yellowish-brown, anal tuft deep black. Rio Grande do Sul; type 1 ♀, allotype, 1 ♂ in the Coll. WERNICKE.

T. castralia Jones. The ♂ is on the body dark purple-brown, the forewing scantily scaled, black, *castralia*, powdered with brownish; median area not darker, its light proximal border-line only distinct at the costal margin, the white distal one in its costal portion straighter than in the other species, the black discal spot hazy; subterminal line only feebly indicated, at the distal margin before the dark brown fringes on the ends of the veins whitish dots. Hindwing with traces of a lighter postmedian band and an indistinct dark discal spot. The ♀ is lighter brownish-grey, the median area edged by darker lines, the anal tuft purple blackish-brown. Castro (Paraná).

T. lanuginosa Schs. (80 b) is a large dark brown species, the median area is not darkened and *lanuginosa*, towards its light border-lines edged with a darker colour, the subterminal line quite indistinct. Abdomen of ♀ lighter greyish-brown, anal tuft blackish, with a slate-coloured silky gloss. South-Eastern Brazil (Sao Paulo).

T. cupriflua sp. n. (80 b, c) is very similar to *fuscicaudata* on the forewing, but the distal border *cupriflua*, of the median area is less sinuate, the subterminal line in the upper third distinct; easily recognisable by the copper-red anal tuft of the ♀. — The larva, according to a water-colour sketch kindly communicated by Mr. GIACOMELLI, is irregularly spotted green on the white ground, with a white dorsal band which is traversed by two fine black lines and shaded with blackish on the 4th and 5th; as well as on the 9th and 10th rings. Argentina. Type in the Mus. Senckenberg; similar specimens in the U. S. Museum in Washington.

T. serralta Jones resembles *cupriflua* by the golden brown anal tuft of the ♀; forewing more brownish, *serralta*, the median band not prominently darker, the light grey proximal border broad, the distal border narrow; the faded undulating subterminal line is light grey; fringes dark brown. Described from Santos (Brazil).

T. scaenica sp. n. (80 c). Colour and marking of forewing similar to *cupriflua*, but the colour is *scaenica*, somewhat more brownish, the median area broader at the costal margin, the light bands are narrow, on both sides edged with a somewhat darker border, also the subterminal line which is more distinct in its anal portion than in its costal portion. Hindwing with a light postmedian band; anal tuft of ♀ yellowish white. Rio Grande do Sul, type in the Coll. WERNICKE, Dresden.

T. simulans Wkr. (80 c) is very similar to *scaenica*, but more brownish, duller, the light bands *simulans*, indistinct, less prominent, the light band of the hindwing only in the ♂ more distinct. Anal tuft of ♀ silvery white. Southern Brazil.

T. nigripuncta Schs. (81 d) resembles *undulosa* and *simulans* on the forewing, but the distal margin *nigripuncta*, is rounder, the light postmedian band less undulating; forewing light grey, with brown veins; the median band is edged by broad brown shadows and centrally lighter, at the cell-end there is a large velvety black spot, subterminally a light brown shadow. Hindwing smoky-brown. Only the ♂ is known. French Guiana.

T. suffusa Jones is dark grey powdered with brown; on the forewing this powdering is the most *suffusa*, distinct, somewhat less in the basal third. A broad, somewhat faded dark brown postmedian transverse band is outwardly angular below the costal margin; at the cell-end a dark spot, the dark undulating line indistinctly waved. Hindwing brown, towards the base grey. Fringes of both wings dark brown. Described from 1 ♀ with an expanse of 58 mm, from Castro, Paraná.

14. Genus: **Titya** Wkr.

The separation from *Tolyte* is, as we already mentioned there, more or less artificial. To this genus the species are placed, with somewhat more elongate forewings showing particularly often in the ♂♂ an extremely short inner margin, and on the hindwing a very oblique cross-vein which is not or but slightly angular. Most of the species are very similar to such of the preceding genus.

Type: *noctilux* Wkr.

T. primitiva Wkr. (= *taruda* Schs.) (80 c) is the main representative of a group of very similar *primitiva*, species. In the ♂ the body is black, the patagia are greyish-white with a flesh-coloured pink tint. Forewing greyish-white with a feeble reddish hue, a blackish median band containing a small black discal spot, before and behind it with finer grey transverse lines, with postmedian and subterminal broader grey nebulous bands; veins yellowish-ochreous. Hindwing blackish-grey with a more or less distinct light narrow marginal band. The ♀ is much larger, dark grey, with more undulating transverse markings, and much larger black marginal spots. Guiana, Colombia.

T. angala Schs. from Bolivia, is very similar to *primitiva*; the shoulders are yellowish salmon-coloured *angala*, like the ground-colour of the forewing, which however is almost covered by broad blackish markings, the median area below the cell broadly interrupted. Margin of hindwing likewise yellowish pink with black internodal dots at the margin. According to 1 ♂ from Rurrenabaque (Bolivia), with an expanse of 35 mm.

- infernalis*. **T. infernalis** Schs. (= *levana* Drc.) (80 c, d) entirely resembles *Tol. celeste* on the forewing, but it is somewhat larger with more intense and darker greyish-black markings. At once separable by the quite dark hindwings. The ♂ is much smaller, with very narrow and pointed wings, almost black with a reddish reflection, with quite indistinct darker markings. Mexico.
- vitreus*. **T. vitreus** Dogn. (80 e). The ♂ has similarly shaped though not quite so pointed wings. Forewing hyaline transparent — but presumably loosely scaled in the freshly hatched specimen —, at the base and inner margin with long grey hairs, with a black cross-vein streak on the forewing and traces of several whitish transverse lines, being mostly more distinct only at the costal margin. Body blackish-grey intermixed with single reddish hairs. Merida (Venezuela). ♀ apparently still unknown.
- avita*. **T. avita** Schs. (80 d) is very closely allied to *vitreus* and *proxima*. Body black, shoulders, sides of collar, and outer half of patagia as well as a transverse line above on the base of the abdomen are light flesh-coloured, also the end of the abdomen beneath. Forewing transparent smoky-grey, finely strewn with blackish, in the basal area and along the inner margin scaled; veins fine white, the markings very similar as in *proxima*, the median transverse lines very close together on vein 2 and connected by a white transverse streak. Hindwing at the anal margin broadly haired smoky-black. The larger ♀ is less transparent; expanse of wings: ♂ 36 mm, ♀ 59 mm. Sao Paulo.
- proxima*. **T. proxima** Burm. (= *argentina* Schs.) (80 d) is extraordinarily similar to *avita*, larger, more robust, somewhat more densely scaled, the median lines less close together, not so strongly notched, not connected on 2, the grey median area behind them broader, patagia not flesh-coloured, at the base of the abdomen 2 flesh-coloured pink hair-tufts on each side. Brazil, Argentina.
- cinerascens*. **T. cinerascens** Wkr. (= *nigra* Schs.) (80 d). The ♂ is smoky-blackish, body quite black; on the forewing the veins are strewn with whitish, towards the apex at the costal margin a few small yellowish-ochreous spots, at the cell-end 2 black dots, and traces of antemedian and subterminal whitish lines. The larger ♀ is loam-coloured grey, the body more brownish, the anal tuft blackish-brown intermixed with single ochreous hairs; forewing with indistinct lighter transverse lines, one black dot each in the cell-angles, and a darker brownish spot below the cell between 3 and 4, some more darkenings being also in front of the light subterminal band on 4 and between 6 and 7. From Venezuela and Guiana.
- bella*. **T. bella** Drc. (80 e) is allied to the preceding species, but it is larger, of a more greyish-brown colour, with more distinct linear markings, the darkened spot of the median area below the cell larger, more distinctly defined by the border-lines, the veins in the postmedian area partly darkened, also the fringe between the veins. Panama. In the Berlin Museum there is a ♀ of *Euglyphis fibra* Schs. labelled as ♀-type of *bella*. SCHAUSS is also of my opinion that the label must have been mistaken, for the figure in the *Biologia* is too unmistakable as to allow this possibility.
- hirtipes*. **T. hirtipes** Wkr. (= *everildis* Schs.) (81 d) is likewise similar, smaller, forewing sand-coloured, the veins in the postmedian and subterminal areas striped blackish-brown, basal area, the spot below vein 4 likewise smoky-blackish as well as a postmedian shadow which is broad at the costal margin and parted by a light line; fringe smoky-black. Hindwing similar with reddish-brown veins. Abdomen brown, the 2 last segments blackish-brown. Castro (Paraná).
- pallida*. **T. pallida** Dogn. (80 e), based upon two much flown ♂♂, in the structure resembles the ♂ of *cinerascens*, but the hindwing is rounder; wings hyaline, light brownish ochreous with 2 black dots in the cell-end. Sao Paulo de Olivença (Amazons).
- synoecura*. **T. synoecura** Dyar (80 c) is most closely allied to *bella*. Wings light fawn-coloured with the same markings as *bella*; anal hair of ♀ ochreous-brown with a golden gloss. The ♂ is lighter, with much lighter hindwings. The larva lives gregariously in nests. Mexico.
- jamaicensis*. **T. jamaicensis** Schs. is smaller, more smoky-grey with the same darkenings at the base and below the centre of the cell and a brown postmedian shadow which is very broad at the costal margin; the brown marginal shadow is narrow, the brown fringe crossed by the light ends of the veins; the distinct light lines of the preceding species are quite absent. Hindwing scantily scaled, light smoky-brown, at the distal margin the lightest. Body greyish-brown with a blackish anal tuft. Expanse of wings: 40 mm. Jamaica.
- gracilis*. **T. gracilis** Dogn. This species described from a ♂ has the shape of the ♂ of *infernalis* (80 c). Body blackish-brown, forewing with a light subterminal line parallel to the margin and about 2 mm distant from it, before that line the wing is blackish-brown, behind it lighter. Hindwing blackish-brown. Rio Tapajoz (Amazons).
- lusciosa*. **T. lusciosa** Dogn. is likewise described to be very similar to *bella*, the ground of the wings scantily scaled, light blackish-brown, the markings grey, as in *bella*, but both the antemedian line as well as the line between the postmedian and subterminal lines are absent; between 5 and 6 there is in the subterminal area a blackish

shadow; fringes black, on the ends of the veins traversed light by the dentate terminal line; hindwing blackish-brown, fringes as on forewing, anal tuft intermixed with ochreous. According to a ♀ from Cali (Colombia).

T. subluca *sp. n.* (86 b). The ♀ exhibits a greyish-brown body; the wings are lighter, more brownish, *subluca*, with fine dark veins, 5 broad, darker brownish, undulating, indistinctly defined transverse bands, 2 antemedian and 3 postmedian ones, beginning much darker below the costal margin; at the cell-end there is a thick blackish spot; distal margin behind the subterminal line likewise darker; before the undulated fringes there is a fine dark limbal line. Hindwing without markings light brownish, at the costal margin somewhat darkened. According to 1 ♀ from Brazil, habitat not mentioned; type in the Berlin Museum.

T. nigrescens *Drc.* (= *nigricolor Dogn.*) (80 e). Hitherto only ♂♂ seem to be known. Black, on the *nigrescens*, wings scantily scaled; a fine marginal line strewn with whitish extends on the ends of the veins into the fringes as in *subluca*; a subterminal line, occasionally a more or less distinct postmedian line, indicated by white dots on the veins. Single white hairs are in front on the forehead and collar, as well as at the base of the abdomen; ventrum yellowish-white. Colombia, Bolivia.

T. arpiana *Schs.* (80 f). Body yellowish-reddish white, thorax and abdomen above with brownish *arpiana*, bands, the forewing with the same markings on the light ground, a line at the base, behind it a spot below the cell, then 3 interrupted, irregular lines and at the cell-end a darker spot from which an interrupted line extends to the inner margin; besides 4 postmedian lines and a fifth line close at the distal margin, in the lower half broken up into spots. Hindwing scantily scaled, white, in the abdominal half dusted with brownish. Abdomen brownish-black. Rio de Janeiro.

T. alma *Weymer* (= *septemlinea Schs.*) (80 e) entirely resembles *arpiana*, but the abdomen above *alma*, is white. The ground of the wings may be somewhat whiter. São Paulo.

T. intercalaris *sp. n.* (80 f) forms a transition from the preceding species to the following *mexicana. intercalaris*. Somewhat larger and more elongate. Forewing feebly iridescent reddish-white, the lines as in *alma*, but more sand-coloured brownish, less distinct; discal dot absent, the whole cell and the space between 5 and 6 as far as the distal margin almost hyaline. Hindwing whitish, smoky except a marginal band, the darkest in the abdominal half. Body whitish, head and collar brownish, thorax and abdomen with yellowish-brown bands. According to 1 ♂ from Espiritu Santo (Brazil). Type in the Coll. WERNICKE, Dresden.

T. mexicana *H.-S.* (= *plurilinea Wkr.*) (80 f) is larger than the preceding species, similar, though *mexicana*, with darker yellowish-brown markings, the transverse lines more or less distinct only in the marginal half and costally, in the basal $\frac{3}{4}$ below the cell flown together into a large shadow. The cell and the space between 5 and 6 as far as the subterminal line hyaline. The ♀ is very much larger, more densely scaled, darker fawn-coloured, the lines rather indistinct, the lightest is the subterminal line which gradually widens from the inner margin to 7 and narrows down again at the costal margin. Anal hair blackish. Mexico to Rio de Janeiro.

T. rivulosa *Btlr.* (= *butleri Berg*) (80 f) resembles the preceding ones, forewing semidiaphanous *rivulosa*, whitish, on the veins with dark spots, with greyish-brown transverse markings: a small basal spot, before the centre with 2 angular bands, then a broad median band interrupted by the hyaline cell, behind it 3 parallel undulating lines, a light brown marginal band, and a series of dark brown marginal spots. Head and prothorax white, metathorax and abdomen brownish. Rio Negro (Colombia).

T. opalina *Wkr.* (= *cervina Wkr.*) (81 e). The ♂ resembles *alma* and *intercalaris*; the narrow forewing *opalina*, at the distal margin dentate, whitish, iridescent, with 2 irregular, broad, reddish antemedian transverse bands and a broad postmedian band, in the latter with 4 whitish undulating lines and finely brown-striped veins between them, the small hindwings feebly yellowish. The ♀ is reddish yellowish-brown with 6 dentate darker transverse lines and an incompletely double whitish subterminal line, and a whitish discal spot between the 3rd and 4th lines. Ega (Amazons).

T. hirta *Stoll* (80 f). The ♀ is scantily scaled, very light yellowish-brown, with 3 broad darker transverse *hirta*, bands, the median band being the broadest, enclosing 2 black dots in the cell-angles, before the darker and lighter speckled fringes with a narrow darker marginal band. Guiana. The larva painted by STOLL looks dark brown with a white dorsal line and 2 yellow lateral lines, and fir-tree-like hairs, on the 1st ring with 4 longer ones, the 2 longest with a white ring. It lives on water-melon. I presume that the ♂♂ described by DOGNIN as *pallida* (80 e) belong hereto.

T. trilinea *Dogn.* (80 g) is somewhat more greyish-brown, the median band interrupted on 2, so *trilinea*, that the light border-lines of the ground-colour form an X here, otherwise very similarly marked as *hirta*. Ecuador (Loja); also from Leopoldina (Brazil).

- angustipennis.* **T. angustipennis** Schs. (81 e). The ♂ has remarkably long and narrow wings; body brown; forewing scantily scaled, strewn with blackish and white, with dark veins; base and inner margin dark brown with traces of lighter brown antemedian and postmedian lines, and with a black subterminal shadow. Hindwing dark brown, towards the margin shaded with black. French Guiana.
- guthagon.* **T. guthagon** Schs. (81 e). The ♀ is light brownish on the scantily scaled wings, with whitish transverse lines, the antemedian line almost vertical, below the cell somewhat bent, between both lines the median vein is blackish-brown and at the cell-end expanded into a small spot; behind the postmedian line at vein 7 a darkening, behind it a fine dark double line, its lower half nearing the postmedian line; subterminal line whitish flesh-coloured, undulately dentate; the white marginal line extends on the ends of the veins into the fringes, so that the distal margin appears to be somewhat dentate. French Guiana.
- fumida.* **T. fumida** Schs. (80 b) is smaller than *guthagon*, darker, more greyish-black, the dark bands very broad, so that the light ground only remains as a narrow line; instead of the discal spot there are 2 dots in the cell-angles. Body darker brownish-grey, in the anal tuft ochreous hair are intermixed. Petropolis, St. Catharina.
- abstersa.* **T. abstersa** Fldr., according to the figure, entirely resembles the *Tolyte*-species from the *simulans*-group. Forewing on the scantily scaled, light brownish ground with faded greyish-black transverse bands, the median band being the broadest, distally projecting twice, on 4 and 9, with a thick blackish faded discal spot. Brazil. The type was neither to be found in Tring nor in Vienna. — **perlonga** f. n. (80 g). As a precaution, I range the figured couple from the Berlin Museum as a form with *abstersa*, because of all the species before me this form is the most corresponding to FELDER'S figure; it may even be *abstersa* itself, although the shape of the wings appears to me to be too elongate. Brazil; the exact habitat is not stated.
- maura.* **T. maura** sp. n. (80 g) is quite unicoloured sooty blackish, scantily scaled, without any marking except the cross-vein being more densely scaled in blackish; veins brownish, fringes somewhat darker, particularly on the hindwing with a bronze reflection. Body covered with very long shaggy sooty black hair. According to 1 ♂ from the Songo (Bolivia) in the Coll. BANG-HAAS.
- noctilux.* **T. noctilux** Wkr. (= *argentata* Schs., *manoba* Schs.) (80 g) differs greatly from all the others. Forewing silvery white, with fine black veins, with a greyish-black oblique band from the apex to the centre of the inner margin. Body and hindwing greyish-brown in the ♀, whilst in the ♂ the hindwing is white, only at the distal margin grey. Venezuela to Brazil.

15. Genus: **Tytocha** Schs.

At once discernible from the preceding genera by only two veins of the forewing rising on a joint stalk from the upper cell-angle, 8 being absent, 9 and 10 rising on a long stalk close before 6 and 7 from the upper edge of the cell. On the hindwing the cell is relatively long. Only 2 species are known

Type: *T. lineata* Dogn.

- lineata.* **T. lineata** Dogn. (= *temperata* Schs.) (81 e) is on the forewing very light pinkish-yellow with darker transverse lines, 3 antemedian and 3 postmedian ones, between them a dark-shaded cross-vein streak; before the broader subterminal shadow there is another interrupted spotted line; at the margin cinnamon-reddish internerval streaks. The abdomen is coloured like the forewing and exhibits darker transverse bands. In the ♀ the ground-colour is more olive grey, only the darker transverse markings show a slight pink tint. Guatemala to Colombia.
- crassilinea.* **T. crassilinea** Dogn. (81 e) is extremely similar to *lineata*, but the ground-colour is semi-transparent white, the transverse markings are brownish. Colombia, Amazons.

16. Genus: **Tolytia** Schs.

Likewise very closely allied to the preceding ones, but the ♂ antennae exhibit short pectinations as far as the tips; abdomen with broad dorsal tufts. Forewing broad, distal margin rounded. Recognisable by the veins 6 and 7 of the forewing rising together on a short stalk from the upper cell-angle, and 8 from the upper cell-angle, 9 being absent, 10 and 11 rising from the cell. On the hindwing 6 rises from 7 before the cell-end. Only 3 rather small species.

Type: *T. multilinea* Schs.

- sanguilenta.* **T. sanguilenta** Dogn. (82 a) is white, on the forewing with 9 somewhat irregular, parallel transverse lines of a greyish-brown colour, with a rusty red irroration on single veins in the disc, being intensified on the transverse bands, as well as 2 dots in the cell-angles. Described from Peru.

T. sana Dogn. is very similar to *sanguilenta*, but the transverse markings are much narrower, partly *sana*. extinct; of the rusty red colour only the upper cell-dot remains as well as the base of the branches 6 and 7. Colombia.

T. multilinea Schs. (82 a) entirely resembles *sanguilenta* in the scheme of markings, but the ground-colour is sulphur, the transverse lines are darker yellow, the veins in the disc partly strewn with blackish. French Guiana and Amazons (before me from Massauary). *multilinea*.

17. Genus: **Sphinta** Schs.

Exterior quite different; structure about the same as that of *Tolyte*, but the ♀ abdomen lacks the thick anal tuft. On the hindwing 7 and 8 rise on a very long stalk contrary to *Artace*. Only two species:

Type: *S. cossoides* Schs.

S. cossoides Schs. (82 a). This species with a stout abdomen and brown forewing showing a broad *cossoides*. slate-coloured costal margin and black dentate lines is unmistakable. Brazil.

S. schausiana Jones (82 a) is smaller than *cossoides*; body brown, collar and patagia grey, with a black *schausiana*. dorsal streak on the thorax. Forewing white with brown veins. Costal margin and cell dark brown, thickly haired and scaled in a greenish grey; below the median vein with a faded dark brown longitudinal stripe and below it with 3 dark brown lunae; another longitudinal stripe is situate between 5 and 6, and below the apex there are 3 dark subterminal spots; distal margin tinted yellowish, fringes brown. The white hindwing is powdered with light brown at the costal and posterior margins, at the anal angle there is a brown spot. Expanse of wings: 43 mm. Curityba, Parana, Brazil.

18. Genus: **Artace** Wkr.

Palpi extremely short, turned downward, in some species of a peculiar red brick-colour; frons and eyes covered by pendent hair-fringes. Veins of forewing as in *Tolyte*. In the hindwing the cross-vein is very oblique, 2 rises behind the centre of the cell, 3 shortly before the lower cell-angle from which 4 and 5 rise together or on a short stalk; 6 from the upper cell-angle, 7 far before it, almost from the middle between 6 and 8. Many similar species.

Type: *A. punctistriga* Wkr.

A. cribraria Ljung (= *punctistriga* Wkr.) (82 a) is one of the oldest and most common species. *cribraria*. Forewing white, with fine dark veins, with rows of black vein-dots, 2 subbasal dots, an antemedian row and 3 postmedian ones, between the two outermost with a very feeble subterminal row of small spots. Distal margin between the veins dotted black. Hindwing with traces of a subterminal shadow-like band. The dots are very variably developed, in some specimens the postmedian row of vein-dots is connected by a fine blackish-grey line: — **connecta** f. n.; such specimens are before me from St. Catharina. Very widely distributed from the *connecta*. Southern Atlantic States of North America down to Argentina and Paraguay.

A. regalis Jones is considerably larger than *cribraria*, of a very pure white, palpi outside black, the *regalis*. rows of black dots arranged as in *cribraria*, but more spot-shaped; the subterminal row of spots is composed of more elongate spots. Hindwing pure white. Castro Parana; Santos.

A. muzophila Dogn. is very near to *cribraria*, of a purer white, with much fewer black dots, the *muzophila*. antemedian row proceeding from a thick brownish-black costal-marginal streak, without discal dots, a subterminal row formed of very feeble pale rusty brownish irroration; at the distal margin only between 7 and 10 some small black dots. Hindwing all white. Described from 1 ♂ from Muzo (Colombia).

A. litterata Dogn. (82 a) is smaller, in the white colour of the body there are grey and black hairs *litterata*. intermixed. Forewing with 7 more or less distinct blackish parallel transverse lines which are partly broken up into black vein-dots and interrupted in the cell; on the margin between the veins with thick black dots, 2 similar ones are situate in the two cell-angles. Hindwing with a subterminal grey marginal band. Brazil (São Paulo).

A. argentina Schs. (82 b) differs in quite black palpi, the thorax being mixed with drab, the abdomen *argentina*. with similar bands. Forewing opalescent white, with a faint sand-coloured hue, the vein-dots otherwise as in the preceding species, but the marginal streaks are absent on the veins; before the marginal spots a fine black marginal line, also on the hindwing. Argentina, Brazil.

- menuve.* **A. menuve** Schs. (82 b) has likewise black palpi, the white body is above tinted with sandy grey. Forewing white, scantily scaled, somewhat opalescent with black dots as in *argentina*, but with black marginal streaks on the veins and without the fine black marginal line, only with the small internerval spots. The white hindwing at the anal margin with light sand-coloured hairs. South-Eastern Brazil (São Paulo).
- sisoes.* **A. sisoes** Schs. (82 b) is a larger species very similar to *cribraria* f. *connecta*; body above with more sandy grey hair. Forewing of ♂ scantily scaled, opalescent, the black dots as in the two preceding species, but the postmedian row forms short vein-streaks, a subterminal grey narrow transverse band is parted by the veins; veins in the marginal area strewn with black. Hindwing with a smoky black subterminal line being the most distinct at the anal angle. In the ♀ the forewing is greyer, the dots are partly connected by lines. Hindwing grey with a white marginal band. Guatemala, Amazons (from Casa Branca in the Coll. STAUDINGER).
- meridionalis.* **A. meridionalis** Schs. In the ♀ the forewing above is white, with 3 rows of dark grey vein-dots and two at the cell-end; subterminally and at the margin one dusty grey transverse band each, and on the margin a row of black internerval spots. Hindwing above grey, at the anal margin darker. Head and thorax grey, abdomen above dark grey, beneath white. Expanse of wings: 44 mm. Tijuca, Rio de Janeiro.
- punctivena.* **A. punctivena** Wkr. (82 b) is very similar, the wings above greyer, but very scantily scaled, particularly the body darker grey; on the forewing the dots as in the preceding species, behind and before the small subterminal grey spots we notice a somewhat more distinct white ground-colour. Hindwing with a feeble grey subterminal band which is only more intense at the anal angle. Colombia, Brazil.
- anula.* **A. anula** Schs. (82 b). Palpi black, forewing white with 6 grey, undulatingly dentate transverse lines, with black vein-streaks interrupted by these lines, the two central lines together forming rings above the inner margin; besides a subterminal grey undulating line, and at the margin black internerval streaks; hindwing with a blackish anal angle; abdomen blackish. In the ♀ the transverse undulating lines and the subterminal band sand-coloured brownish. Hindwing smoky excepting the white margin and a narrow subterminal band. Brazil.
- coprea.* **A. coprea** sp. n. (82 c) is a very large species of a quite dark colour, on the yellowish-red ground densely dusted with a neutral grey, the darkest in the subterminal area; veins still darker yellowish-red, the rows of vein-dots strigiform, on vein 2 five black streaks at equal distances, the black internerval dots at the margin very thick. Thorax dark neutral grey, intermixed with yellow-reddish hairs. Abdomen absent. Hindwing on the yellowish-red ground densely powdered with grey. According to 1 ♀ without any habitat stated, presumably from Brazil (type in the Berlin Museum).
- lilloi.* **A. lilloi** Giac. (81 e) is a very different small species, uniformly light ashy grey, the legs with somewhat darker rings; on the forewing from the centre of the inner margin to the apex a black oblique line, but not quite reaching the apex; at the cross-vein there is a comma-shaped black streak; the oblique line may also be absent; all the veins distinctly black, at the margin there are black internerval spots. Expanse of wings: 22 mm. La Rioja (Argentina).
- helier.* **A. helier** Schs. (82 c). This species belongs to the group of species with red palpi; palpi blackish-brown, the last joint carmine; the white body is covered with drab hair; on the abdomen with dark transverse lines. Forewing light neutral grey, with darker grey transverse lines, the costal margin and veins white, on all the lines with short black vein-streaks, the subterminal shadow more spotted; the small terminal spots extend into the fringes. Hindwing whitish with a grey anal margin and distal-marginal band. The ♀ is larger and scantily scaled. Castro (Parana), Rio de Janeiro.
- aemula.* **A. aemula** sp. n. (82 c) is allied to *helier*, but also similar to *anula* from which it differs in the rosy red palpi. Body with very light sand-coloured hair. Forewing very light brownish-white, costal margin not pink at the base, with very indistinct dull and blurred sandy brownish undulate lines and a somewhat more distinctly prominent median band; behind the row of subterminal spots the margin is somewhat whiter with extremely feeble, brownish, anteterminal diffuse spots; in this species the fringes are speckled with brownish-grey. Hindwing whitish, powdered with a sand-like brownish colour almost as far as the margin. The abdomen is absent in the only ♀ from Rio Grande do Sul. Type in the Coll. BANG-HAAS.
- nigripalpis.* **A. nigripalpis** Dogn., described according to a ♀ from Loja, Ecuador, entirely resembles *rubripalpis*, but it has black palpi, nor any red at the costal margin. Body and wings white, the black dots as usual, above the 2 dots at the cell-end there is another dot at the costal margin, the dots of the postmedian line on 6, 7 and 8 distally removed, hindwing all white, with black marginal dots as on the forewing.
- albicans.* **A. albicans** Wkr. has red palpi, towards the base black; forewing white, at the base of the costa red, with the usual rows of vein-dots, a subterminal row of small brownish spots, and on the margin with the usual black small internerval spots. Brazil; the statement „Georgia“ is surely wrong.

A. rubripalpis *Fldr.* (82 c) is smaller and greyer than *albicans*, the palpi and the base of the costal margin *rubripalpis*. being red, the vein-dots particularly in the ♂ more strigiform, in the ♀ by connecting shadows arranged more as transverse lines, the terminal spots very large, oval. Rio Grande do Sul. The frequent statement of its being a synonym of *cribraria* is wrong.

A. rosea *sp. n.* (82 c) is marked almost like *menuve* or *helier*, but the ground-colour is pink, on the *rosea*. forewing with a grey longitudinal patch through the cell as far as the margin. Hindwing white with a smoky anal spot and black marginal dots. Abdomen above black, anal tuft red-brown. Palpi and base of costal margin crimson. According to 1 ♂ from Rio de Janeiro. Type in the Coll. SENCKENBERG.

19. Genus: **Euglyphis** *Hbn.*

This genus being also called *Hydrias*, *Claphe*, or *Eriogaster* comprises an enormous number of species the size of which varies between more than medium and small, the sexes being mostly very differently large, the considerably larger ♀♀ exhibiting a very stout abdomen. The eyes are bare, the palpi rising obliquely or being more or less horizontal are rather long, the second joint thickly haired, the 3rd hidden in the hair. Proboscis stunted. Antennae rather short, of $\frac{1}{3}$ to $\frac{1}{4}$ of the length of the costal margin, in the ♂ in the basal half with rather long pectinations, in the terminal half just as long or shorter, in the ♀ short pectinated, at the base with a hair-tuft. Body and legs strongly haired, abdomen above with hair-tufts on the 3 or 4 first rings or also without them, hind tibiae and tarsi very long-haired. Forewing broad with slightly roundish costal and distal margins, apex rounded or, particularly in the ♂, more pointed. Vein 2 rises very near the base, about midway between 2 and 4, the latter with 5 from the lower cell-angle together or slightly separated; the cross-vein is very feebly developed; 6 rises on a stalk with 7 from the upper cell-angle, more or less near the margin 8 rises from the latter; 9 and 10 on a long stalk shortly before it, 11 separated from them from the centre of the upper edge of the cell, being later on coalescent with 12, at about its centre. On the hindwing the costal margin is very convex, or only at the base convex, behind it occasionally concave, sometimes also before the produced apex with a concavity, the distal margin often dentate. The cross-vein is very feebly developed, the lower angle usually very much produced. 2 rises from the centre of the cell, 3 midway between 2 and the veins 4 and 5 rising from the lower cell-angle; 6 rises together with 7 from the upper cell-angle or the latter shortly before it, 8 and 9 close together near the base, shortly behind the latter a short, strongly bent vein 10 proceeds; the basal loop is very indistinct.

The small group assembled around the type of the genus is distinguished by black hair directed towards the costal margin, in the basal half of the inner margin.

Type: *E. claudia* *Stoll*.

E. claudia *Stoll* (= *marginalis* *Wkr.*). Forewing light reddish-yellow like the body, but this colour *claudia*. remains pure only at the inner margin and distal margin as well as in a larger, obliquely quadrangular spot at the anal angle extending to the upper median branch; the whole basal half is in the same way as in the 6 following species darkened by black and single white hairs turned towards the costal margin, the basal quarter being the darkest, separated by white wavy lines from a median area which is edged by somewhat darker lines; at the cell-end two dots obliquely below each other; behind the median area projecting twice pointedly the upper two thirds of the postmedian area are darkened grey as far as the broadly whitish dusted subterminal area in which there are greyish-black undulate linear spots, the spot between the upper radials projecting far inwards. Hindwing greyish-brown, at the distal margin reddish-yellow, at the costal margin traversed by several angular white lines, and with a dark median line, the subterminal row of spots being also here distinct. The type is from Surinam, WALKER's type from Pará. The species is very variable, southern specimens (St. Catharina) are mostly more darkened, so that there remains hardly any trace of the reddish-yellow colour which has turned more yellowish-grey, and the bordering of the median area is more or less extinct, too: — **f. conspersa** *nov.* (82 d). The ♀ is duller and more monotonous. — **folia** *Schs.* (82 d) is very similar and probably *conspersa*. *folia*. not specifically different; it differs in the absence of the dark median line on the hindwing.

E. aleria *Drc.* (82 d) is very similarly marked as *claudia*, but larger and much more monotonously *aleria*. greyish-brown, the marginal area hardly lighter, the light anal spot is entirely absent, the two discal dots are changed into an oblique thick streak; the fine white undulate line, on the inside of which there are small greyish-black spots, is crossed by fine yellowish veins. On the monotonously greyish-brown hindwing there is a rather large, prominent, dark subapical spot at the costal margin. Brazil, Ecuador, Bolivia.

E. ocyroe *Dogn.* (82 d) is closely allied to the preceding ones, darker, more olive-grey, the inner- *ocyroe*. marginal half shaded by a darker longitudinal band, the thick black discal spot removed far inwards, the outer border of the median area indicated by short black vein-streaks at least in the costal-marginal half; the white undulate line as in the preceding species, though forming higher pointed arches, at the anal angle mostly a larger white spot. Hindwing in the basal half of the anal margin with a slight rust-brown tint. Mexico, Colombia, Ecuador.

- reversa.* **E. reversa** *sp. n.* (82 d) is very similar to *ocyroe*, with clearer markings and at once discernible by the reversedly coloured hindwing the costal-marginal half of which is broadly rusty brown, the anal-marginal portion being light whitish; also the body and the inner margin of the forewing are mixed with rusty red. According to 1 ♂ from the Rio Songo (FASSEL). Type in the Berlin Museum.
- sommeri.* **E. sommeri** *sp. n.* (82 c) is much smaller than the preceding species and much lighter, white, with the same characteristical upturned hairing being composed of black, rusty yellow, and white hairs; scheme of marking the same as in *ocyroe*, but the black discal spot removed very much farther outwards; the white undulating line as in *claudia*, with rounder arches than in *ocyroe*, the black spots before it as in *claudia*. Hindwing almost white, in the anal-marginal third powdered with brown, with a distinct subterminal line composed of small spots, and blackish fringes which are crossed by whitish on the ends of the veins. Thorax clad with long black and white hair, with a contrastingly bright copper or bronze coloured prothoracal tuft, also the strong abdominal tufts being bronze-brown, intermixed with thick bluish-black hairs. Described according to 3 ♂♂; type e Coll. SOMMER in the Berlin Museum, habitat not mentioned; a larger ♂ with somewhat brighter colours, which we figure, in the Coll. W. HOPP. Charlottenburg, from São Paulo.
- submarginalis.* **E. submarginalis** *Wkr.* (= *praxitheia* *Drc.*) (82 e) belongs yet to the same group, being the most closely allied to *ocyroe*, larger, darker and much more monotonously olive blackish, marking entirely obliterated, only the white pointed arches of the undulating line with a larger white anal spot are distinct, the rest of the marking being composed of very indistinct darker wavy lines. The ♀ is much larger and more monotonous, more scantily scaled, the very large dorsal tufts on the abdomen intermixed with thick steel-blue spatulate hairs. Mexico to Colombia and Brazil, everywhere common.
- catenifera.* **E. catenifera** *sp. n.* (82 c) is likewise allied with the preceding ones; forewing greyish-brown, the erect hair shorter, blackish, with a large triangular velvety blackish-brown basal spot not reaching the costal and inner margins, with a thick round discal spot; the median area is shaped as in *claudia*, not darker, edged by faded darker transverse bands; the undulate-linear spots as in *claudia*, but representing thicker and rounder black spots, the two situate between the radial branches combined forming a large, inwardly removed triangular spot, outside with a hardly lighter border, without the white arches of the undulating line of the preceding species. Hindwing duller brownish-grey, the spots of the undulating line feebly darker, in the centre of the costal margin with a large black spot distally edged with whitish. According to 1 ♀ from Sarayacu (East Peru). Type in the Berlin Museum in the Coll. STAUDINGER; also from Macas (Ecuador).
- princeps.* **E. princeps** *Dogn.* (82 f) as well as the following *riphea* are distinguished by orange-red and chalky white strewing with peculiar thick scales in the basal half between the submedian and cell. Forewing brown, in the basal two thirds darker; antemedian line only indicated by whitish double streaks at the costal and inner margins, the white postmedian line being double; subterminal line composed of white lunar streaks which are inwards shaded with blackish. The brown hindwing with a strongly notched subterminal line and half double postmedian line. Abdomen with dark and light rings. Guiana; Amazons.
- riphea.* **E. riphea** *Stoll* (82 f). This beautiful species is evidently very similar to *princeps* and exhibits the same orange colouring of the submedian base and chalky white scales strewn on it. Forewing lighter reddish-brown, marked as *princeps*, but unmistakable by the median area in the disc being filled with a deep brownish black. Surinam; 1 ♂ which we figure from São Paulo, in the Berlin Museum. The species seems to be uncommonly rare.
- rivulosa.* **E. rivulosa** *Dru.* KIRBY considers this very questionable species to be synonymous with *riphea*, but SCHAUS is of a different opinion. The figure is too indistinct, and the species will probably never be identified. Surinam.
- lucilla.* **E. lucilla** *Stoll* has remained unknown to me. The figure represents a large species, the marking and whole habitus undoubtedly recalls *princeps*, but with much broader wings. Blackish-brown, forewing particularly at the base strewn with black, with 3 light yellowish-brown postmedian transverse bands, the subterminal band inside bordered with blackish spots; on the hindwing two transverse bands and a broad blackish, distally whitish subterminal band are indicated, extending to the anal margin. Surinam.
- ornata.* **E. ornata** *Stoll* (= *phidonia* *Stoll*, *ornanda* *Hbn.*) (82 f). Distinguished by the long narrow shape of the wings. Forewing greyish-white, with fine brown veins, with a darker irroration and 3 transverse lines, the two first of which are mostly indistinct, the subterminal line forming very high pointed dents on the veins. Abdomen and anal-marginal half of hindwing red-brown, the hindwing with a sharply notched subterminal line distally bordered with whitish. Costa Rica; Guiana to Brazil.
- phedonioides.* **E. phedonioides** *Schs.* is very similar to *ornata*, but smaller, lighter, and with less long forewings. Whitish-grey, finely strewn with brown; postmedianly with short white vein-streaks, before them dark brown, the deeply dentate subterminal line dark grey, the brown fringes feebly speckled with white, in the centre of the inner margin with a blackish-brown spot. Abdomen and hindwing ochreous brown, the latter with a feeble dark median line. Expanse of wings: 37 mm. Costa Rica.

E. revincta *sp. n.* (82 f) exhibits still somewhat longer forewings than the other species, darker greyish-white, strewn with brown, with similar transverse lines, the antemedian line distinct, at the upper edge of the cell projecting far distad in an acute angle, on the veins notched as far as the inner margin; in the lower cell-angle there is a fine black dot; the postmedian line is double, the interior portion complete, on the veins inwardly notched, between them projecting outwards with round arches, the exterior portion only distinct on the veins; subterminal line forming regular dents, though not such high ones as in *ornata*, parallel to the margin. Hindwing as in *ornata*; in the basal portion of the forewing a few yellow scales are intermixed, as in the basal portion of the costal margin on the hindwing. Described from 1 ♂ from Peru (type in the Berlin Museum). *revincta.*

E. durtea *Schs.* (82 f). Anterior body grey, abdomen light red-brown, basally with black dorsal tufts. Forewing dark grey, with black veins; subcostally at the base of the cell, above the submedian, and between 5 and 6 with brown stripes; the anterior and posterior dark transverse lines double, the dentate subterminal line black, at the cross-vein a black line. Hindwing light brown, costal margin and apex as on forewing, with a short dark postmedian line and a subterminal line, and black veins in the marginal portion. French Guiana. *durtea.*

E. supertheresa *Dogn.* is very near to the following *theresa*, somewhat larger, lighter, more greenish grey, with a brown longitudinal shadow through the disc as far as the distal margin; on the hindwing the two colours grey and brown are sharply separated. Guiana to Peru. *supertheresa.*

E. theresa *Schs.* (82 f) is on the forewing grey, strewn with brownish, with black veins particularly towards the margin, and with 2 black cellular dots; antemedian line indistinct, postmedian line with round arches, subterminal line projecting on the veins in very pointed dents, the area before it somewhat lighter. Hindwing in the interior half brown, with a dentate dark grey subterminal line and traces of a median line. The nomenclatural form described from Brazil (Rio de Janeiro). — More to the north, in Mexico, the species occurs in a much darker, intensely black-strewn form, with distinct white dots in the notches of the postmedian line: **mexicana** *f. n.* (82 g). The ♀ is much larger and more monotonous, with feebler markings. *theresa.* *mexicana.*

E. albiserrata *sp. n.* (82 g) is the most closely allied to *theresa*, but larger and much darker, on the forewing olive blackish, with black veins, between the deep dents of the single antemedian and postmedian lines filled with white, before the very long and deeply dentate subterminal line there is whitish irroration. Hindwing red-brown, in the costal-marginal portion on both sides bordered with whitish. Colombia and Amazons. ♂ type from São Paulo de Olivença in the Berlin Museum in the Coll. STAUDINGER. *albiserrata.*

E. teresina *Schs.* (82 g) shows the colouring of *supertheresa*, but it lacks the brown longitudinal shadow through the disc, and the postmedian line is less deeply dentate; the dentate antemedian line is double. It also resembles *revincta* to some degree, but it is smaller, the forewing less elongate, the subterminal line is not quite parallel to the margin, but between 4 and 6 it recedes slightly towards the base. From French Guiana. *teresina.*

E. geminata *Dogn.* is allied to *teresina*; anterior body and forewing whitish-grey, strewn with brown; both the transverse lines are double, the anterior one submedianly angular, the posterior one regularly dentate, between them two cell-end dots; subterminal line single, deeply dentate, behind it and on the transverse lines the veins are marked with black. Hindwing and abdomen light reddish yellowish-brown, the latter with a whitish anal tuft, the former with a double postmedian line, before and behind it in the light costal portion strewn with blackish; near the margin there is a complete subterminal line. Fringes speckled black and white. Described from 2 ♂♂ from the Amazons (Obidos). *geminata.*

E. viridescens *Dogn.* (81 f). Forewing strewn with greenish, black and white scales, producing a moss-greenish tint, in the ♂ the postdiscal and inner-marginal areas are more intensely strewn with white; the two transverse lines are conspicuous by white vein-dots, the black subterminal line is strongly dentate. Abdomen and anal-marginal half of hindwing rusty brown, hindwing with a black, dentate subterminal line, in the costal-marginal half bordered with white, and here besides with a white, not dentate median line. Peru (Yahuarmayo). *viridescens.*

E. napala *Schs.* (82 g) is marked as *theresa*, but the ground-colour is a dull olive brown, with darker veins; anterior transverse line only shadow-like; posterior line only double at the costal margin; on the hindwing the costal-marginal portion is strewn in a darker colour, therein with a double postmedian line, the subterminal line extends to the anal angle. Guiana. *napala.*

E. insuta *sp. n.* (82 h) is similar to *napala*; ground-colour more rusty brown, head, collar, and patagia with whitish-grey hairs. Basal portion of forewing and costal-marginal portion of hindwing strewn with white, antemedian line double in the costal-marginal portion, the postmedian line single, deeply dentate, on the veins dotted white; postmedian area somewhat lighter, subterminal line very deeply dentate, slightly receding on 5, the veins behind it black. Hindwing with a black median line extending to vein 5, and a black subterminal line extending to the anal angle. Described from 1 ♂ from São Paulo. Type in the Berlin Museum. *insuta.*

E. napalona *sp. n.* (82 h) is likewise similar, somewhat larger, more slender, with a longer abdomen, bright red-brown, without the whitish strewing of *insuta*, veins fine black, the antemedian line is entirely absent on the forewing, the postmedian line at the costal margin indistinctly double; the median area below the cell slightly powdered with purple, with thick black veins; postmedian area below the costal margin and between *napalona.*

3 and 4 somewhat lighter; the subterminal line recedes between 4 and 6, and is replaced here by two black longitudinal patches. Hindwing in the costal portion coloured like the rest of the wing, the subterminal line farther remote from the margin. According to 1 ♂ from Chanchamayo (Peru). ♂ type in the Berlin Museum in the Coll. STAUDINGER. ♀ type from Medina (Eastern Colombia) in the Coll. BANG-HAAS. According to SCHAUS also in the U. S. National Museum, without any denomination.

napaloides.

E. napaloides Dogn. is larger than the very similar *napala*, on the brown forewing strewn with white, the double antemedian line only extends to the median, the double postmedian line is hardly undulating, the strongly notched subterminal line receding between 4 and 6. The brown hindwing is strewn with white in the costal-marginal half, here with a double postmedian line; the subterminal line as in *napala* and its allies. French Guiana.

napalita.

E. napalita sp. n. (82 h) is most closely allied to *napalona*, but smaller and somewhat darker, without the postmedian brightenings, the antemedian line double in the costal-marginal portion, subcostally very long dentate towards the margin, like the single postmedian line and the subterminal line, the former without the white vein-dots, the latter in the costal-marginal portion double, filled with a somewhat lighter colour and very long and obliquely projecting towards the margin on 9. Hindwing monotonously dark brown, in the costal portion not contrasting, the subterminal line nearer to the margin than in *napalona*. ♂ type from Iquitos in the Berlin Museum in the Coll. STAUDINGER.

sordida.

E. sordida Schs. (82 h) is brownish on the forewing, strewn with grey, only the dentate postmedian line and the deeply dentate subterminal line being visible, the narrow subterminal area slightly lighter, in the marginal portion the veins very fine black. Hindwing brown, costally strewn with grey, with a feeble subterminal line not reaching to the anal angle. Brazil.

maria.

E. maria Schs. (82 h) likewise belongs yet to the *theresa*-group. Anterior body and forewing yellowish reddish-brown, densely strewn with black as far as the posterior transverse line, the latter with white vein-dots, the anterior line more or less indistinct, between them a small black cell-end spot; behind the deeply dentate subterminal line with black vein-streaks ending white on the brown fringes. Abdomen and hindwing brown, hindwing in the costal-marginal portion as on the forewing, the subterminal line together with the black vein-streaks forms round, somewhat lighter, small marginal spots. From Costa Rica.

marissima.

E. marissima Dogn. is very similar, on the forewing more chestnut-brown, with darker veins, only traces of the transverse lines, the postmedian line with vein-dots; the dentate subterminal line hardly contrasting with the ground-colour. Hindwing brown, in the anal-marginal half lighter and more monotonous, the dentate subterminal line only apically visible. French Guiana.

gurda.

E. gurda Dogn. (83 a) is allied to *maria*, somewhat larger, brownish ashy-grey, basally and before the subterminal line strewn with whitish, with indistinct dentate transverse lines, the posterior one with white vein-dots, between both a sharply angled black discal streak; the sharply notched subterminal line incurved between 4 and 6, the black vein-streaks behind it terminate on the fringes with white dots. Hindwing brown, in the costal-marginal portion more greyish-black, with the beginning of a whitish median line; subterminal line not very strong, behind it the distal margin is somewhat lighter. Prothorax with whitish hair, the brown abdomen above with whitish-grey hair and black dorsal tufts. Peru and Colombia.

interula.

E. interula Dogn. (81 f). Head and thorax blackish-grey, frons and abdomen brown. Forewing lustrous light reddish-yellow, strewn with white, the median area black, strewn with white, bordered by the very indistinct transverse lines, the posterior line double with vein-dots; behind the strongly dentate subterminal line with black veins of the marginal area, fringes speckled black and light. Hindwing brown, in the costal-marginal portion on the reddish ground strewn with black, with 2 black short lines bordered with white, the subterminal line almost to the anal angle, the veins behind it black. Expanse of wings: 37 mm. São Paulo.

mucida.

E. mucida sp. n. (83 a) has much broader forewings with a rounder apex; greyish-brown, strewn with blackish, antemedian line double at the costal margin, postmedian line likewise double, the latter filled with light, so that a light line is produced from the costal margin to the inner margin, before it a black cell-end spot; the subterminal line forms inwards black sagittary streaks, in contrast with the other species it is outside bordered with light, not inside; fringes speckled. Hindwing brown, costal-marginal portion strewn with black, here with a short light median line; behind the subterminal line reaching to the anal angle the margin is lighter. Head and thorax covered with greyish-white hair. Type: 1 ♂ from South Brazil in the Berlin Museum.

congruens.

E. congruens Dogn. is more red-brown than *gurda*, the postmedian line is stronger, with short dents, subcostally not angular, hardly rounded; the subterminal line forms on 4 a large spot of the ground-colour, the space before it is whitish, excepting the costal portion. Forewing and costal area of hindwing with red hairs. South-Eastern Peru.

canescens.

E. canescens Dogn. (81 f) belongs to the *adusta*-group; forewing grey with a faint red-brown tint, apically and terminally lighter whitish; transverse lines darker, the anterior line irregular, close behind it the cellular dot, the posterior line subcostally angular, hardly dentate, outside bordered with whitish, straight to the inner margin, the subterminal line feebly dentate, subcostally and between 3 and 5 inwardly angular,

dying away on 2; the grey fringes on the ends of the veins white. Hindwing white, costally grey, disc and anal margin with reddish-yellow hair, costally with a median line and a dentate subterminal line; the latter between 3 and 5 inwardly removed. Ends of veins grey, on the fringes white. Thorax reddish-grey. Expanse of wings: 39—41 mm. Merida (Venezuela).

E. filispinosa *sp. n.* (83 a) is allied to *gurda* by the angular cell-end streak; anterior body greyish-white, intermixed with black hairs, abdomen brown with black dorsal tufts and grey anal hair. Forewing greyish-white, in the disc light brownish with thick black transverse lines, the anterior line notched, at the costal margin double, the posterior line double, below the costal margin obliquely distad, then almost vertical to the inner margin, the interior portion of black dents, the exterior portion more composed of brown diffuse spots; subterminal line deeply notched with black vein-streaks behind it, before the grey-speckled fringes with a white marginal line. Hindwing light brown, in the costal-marginal portion grey with a white postmedian line and a notched subterminal line which extends to the anal angle and behind which the marginal area is whitish. Type: 1 ♂ from Joinville (Brazil) in the Berlin Museum.

E. sulga *Schs.* (83 a). Head and thorax whitish-grey. Abdomen above dark grey, mixed with brown, beneath reddish-brown. Forewing grey, strewn with brown, both the transverse lines are quite absent, at the cell-end a black dot; at the base of the costa there is an oblique, light reddish-brown patch, at the centre of the inner margin an oblong light grey spot, distal area somewhat lighter reddish; veins fine black, subterminal line notched. Hindwing brown, in the costal-marginal portion like the forewing, which colour extends behind the entirely extinct subterminal line as small spots between the fine black veins almost to the anal angle. Guiana.

E. simia *Dogn.* (83 a) is allied to *sulga* by the marking of the forewing; ashy grey with a faint pinkish tint, strewn with black, both the transverse lines extremely feeble, the posterior one only marked at the costal margin, the acute angles of the subterminal line more distinct, the veins very fine black. Hindwing very light brownish-white, at the anal margin with yellowish hair, in the costal-marginal portion pinkish-grey, behind the feebly indicated subterminal line with fine vein-streaks. Abdomen yellowish reddish-brown. From Merida (Venezuela).

E. simiola *sp. n.* (83 a) resembles *simia* by the light hindwing. Forewing on the whitish ground strewn with light cinnamon-reddish, veins finely cinnamon-brown, the anterior transverse line absent, the shadow-like posterior line is double, extending obliquely outwards from the costal margin, then pointedly broken in a slight bend obliquely inwards to the inner margin; at the cell-end a small dark spot; the subterminal line is only indicated by blackish-brown wedge-shaped diffuse spots situate inwards to it; fringes on the ends of the veins crossed by white. Hindwing almost white, at the anal margin feebly haired yellowish, in the costal-marginal portion light cinnamon-reddish, with a pointedly notched subterminal line extending to vein 5, behind this line the margin is white; fringes speckled with cinnamon-brown. Body cinnamon-brown. Head and thorax intermixed with yellowish-white hairs. According to 1 ♂ from Venezuela. Type in the Berlin Museum.

E. plana *Wkr.* (83 b) is a smaller species, brownish-white, strewn with a darker colour, at the costal margin almost pure white, strewn with black, anterior transverse line quite indistinct, posterior line dentate, the veins before it fine black; the long dents of the brown subterminal line extending outside as far as the fringes, inside as far as the postmedian line. Hindwing light cinnamon-brownish, in the costal-marginal portion greyish-white, the subterminal line only extending to vein 5. The ♀ is but little larger and not so distinctly marked. Espiritu Santo (Brazil).

E. planita *Schs.* (83 b) is very similar, but the forewing entirely lacks the long subterminal dents, on the hindwing the subterminal line, however, extends to the anal angle, behind it the distal margin it strewn with white. Villarica (Paraguay).

E. adusta *Wkr.* (= *rubiginosa* *Fldr.*) (83 b) is a large species. Anterior body greyish-white, intermixed with single black hairs, abdomen brown with black dorsal tufts. Forewing greyish-white, strewn with black, with cinnamon brownish-pink longitudinal stripes subcostally, through the cell and submedianly; with the same colour the marginal area is strewn; veins black, transverse lines as in *gurda*, the anterior line distinctly double, also the discal streak is angular. Hindwing light brown, in the costal-marginal portion as on the forewing with a short double postmedian and subterminal line. The ♀ is very much more intensely strewn with red. Anterior body darker grey. Distributed in Brazil.

E. dicax *sp. n.* (83 b) is allied to *adusta*, smaller, without the pink stripes, the whole basal area as far as the antemedian line darkened with brown and jet-black hairs, the median area narrower than in *adusta*, the veins therein thickly scaled chalky white, so that particularly the costal-marginal portion appears all white; instead of the angular streak at the cell-end there are 2 black short longitudinal streaks above each other, connected by brown shading; the area between the double postmedian line on the veins white-spotted; the veins in the marginal area are not thickly marked with black, but only feebly brown. Hindwing light fawn-coloured in the costal-marginal portion and in the inner-marginal portion of the forewing thickly scaled white. According to 1 ♂ from Campo Bello (Rio de Janeiro, Brazil); type in the Coll. W. Hopp, Charlottenburg.

E. zikani *sp. n.* (83 c) differs from *dicax* in its broader forewings. Thorax black mixed with single white hairs, on the shoulders with brown hairs. Abdomen red-brown, the black hairs of the dorsal tufts at the tips white, anal hair grey. Forewing in the basal portion chalky white strewn with large black scales, otherwise on the brownish-white ground strewn with white and particularly in the median area thickly strewn

with black, the veins black; transverse lines double, the subterminal line as in *adusta*, receding far on 5 in the shape of a blackish diffuse spot; the black fringes on the veins broadly crossed by light brown. Hindwing light coffee-brown, in the whitish costal-marginal portion thickly strewn with black, with a white postmedian line; the subterminal line extends to the anal angle, behind it the margin is lighter. According to 1 ♂ from Passa Quatro (Sul de Minas), South-Eastern Brazil (Zikan leg.); type in the Coll. W. HOPP, Charlottenburg.

gibea. **E. gibea** Drc. (= *macasibia* Strd.) (83 c) is very near to *adusta*, the forewing lighter greyish-white, almost without any strewing, the transverse lines in the costal-marginal portion indistinct, the subterminal line also less prominent, its dents outside filled with rosy red; of the same colour are the longitudinal stripes. Bolivia, Peru.

agresta. **E. agresta** Stoll has remained unknown. The ♂ is described as rusty brown, on the forewing with 2 whitish transverse bands and on the hindwing with a costal-marginal spot of a whitish colour, the hindwing partly bordered with blackish-brown. Surinam.

nebulosa. **E. nebulosa** Maass. is likewise unknown to me; thorax and forewing brownish-grey, strewn with brown and grey, at the distal margin lighter, in the disc on the veins striped brown. Antennae, abdomen, and hindwing light yellowish-brown, hindwing at the costal margin dark greyish-brown, along the distal margin with whitish-grey spots, parted by the dark brown veins, the subterminal line indicated by the contrast of the colours. Expanse of wings: 20 mm. Described and figured from 1 ♂ from Colombia.

crepuscularis. **E. crepuscularis** sp. n. (83 c) is evidently closely allied to *nebulosa*. Anterior body and forewing light grey, strewn with brownish, with 4 shadow-like darker transverse bands, somewhat distally angular below the costal margin, the veins near the bands partly finely marked with black; behind the undulatingly dentate subterminal line, which is inside feebly shaded with a darker colour, there are somewhat more distinct dark vein-streaks ending whitish on the dark grey fringes. Hindwing and abdomen light brown, the costal-marginal portion of the hindwing coloured as on the forewing, with shadow-like beginnings of transverse bands. According to 1 ♀ from Mt. Tolima (Colombia) in the Berlin Museum.

elena. **E. elena** Schs. (83 c). Anterior body greyish-white, with dark brown hair, abdomen light brown. Forewing grey strewn with white, towards the margin feebly brownish, in the median area below the cell strewn with black; anterior transverse line partly double, dentate, the posterior line likewise so, with white vein-dots, the veins in the median area partly black; behind the subterminal line likewise black vein-streaks, those on 2, 3 and 5 extending farther inwards. Hindwing light brown, at the costal margin as on the forewing, the subterminal line extends almost to the anal angle. Costa Rica.

herberti. **E. herberti** Schs. (= *palumba* Dogn.) (83 c). Colour and marking somewhat similar to *elena*, but the antemedian line, which exhibits in the cell a pointed tooth towards the base, is much nearer to the base, and the much straighter postmedian line is removed farther into the centre of the wing, its distal double portion is but very indistinct; subterminal line more pointedly dentate and more remote from the margin, also on the hindwings on which there are but very indistinct beginnings of the postmedian lines. South-Eastern Peru: Bolivia (Rio Songo).

mya. **E. mya** Schs. (81 f). Body above blackish with grey and yellowish-red hair. Forewing blackish-brown, at the distal margin broadly whitish-grey with a very thick black subterminal line in it, the distal margin strewn with a darker grey; instead of the postmedian line white vein-dots before which there are velvety black vein-streaks, also at the margin black vein-streaks. Hindwing dark brown, at the costal margin blackish with a whitish-grey apical area enclosing the dentate dark subterminal line, and the whitish postmedian line. Expanse of wings: 37 mm. French Guiana.

roseonigra. **E. roseonigra** Dogn. (81 g) is allied to *mya*. Forewing blackish-grey with darker veins, the submedian area, the space between 5 and 7 in the proximal section, a subterminal band and a marginal band, the latter two faded and dentate, rusty brownish mixed with pink; the black fringes with white vein-dots. Hindwing blackish-brown, in the costal-marginal portion blackish-grey, the dentate subterminal line only partly present. Described from a ♀ from French Guiana.

laverna. **E. laverna** Schs. Head, collar, and patagia yellowish lilac pink mixed with brown, thorax and dorsal tufts on the light red-brown abdomen black and dark brown. Forewing yellowish pink, densely strewn with red-brown; the black anterior transverse line is irregular, before it a fine red-brown line; postmedian line black, dentate as far as 4, then undulating to the hindmargin, outside shaded with greyish-brown, broader between 7 and 9; a subterminal greyish-brown dentate shadow. Hindwing yellowish-pink, in the costal-marginal portion strewn with red-brown with a dark postmedian and subterminal shadow, the latter only as far as the anal angle. Expanse of wings: 37 mm. Allied with *adusta* Wkr. Costa Rica. (Banana River).

senecis. **E. senecis** Schs. (81 g) is a small species, body dark olive-brown mixed with white, abdomen laterally red-brown. Forewing dark olive brownish, suffused with yellowish-red, before the centre in the cell mixed with black with white irroration which extends also across the median area; veins in the distal half black, at the margin thickened; at the cell-end there is a black dot; postmedian line blackish-brown, at the costal margin double and distally angular, then with white vein-dots almost vertical to the inner margin; subterminal line

incurved between 6 and 4, between 4 and 3 inwardly dentate; fringes on the ends of the veins speckled with white. Hindwing light reddish ochreous, at the anal margin with darker hair, at the costal-marginal portion as on the forewing, with a dark subterminal line and vein-streaks behind it. Expanse of wings: 27 mm. *Villarica* (Paraguay).

E. melca Schs. Body above grey, beneath light brown. Forewing light grey, strewn with brown and black, with a black cellular dot and an indistinct postmedian row of white vein-dots; before the grey dentate subterminal line powdered with whitish, behind it black vein-streaks ending white on the dark grey fringe. Hindwing similar, in the anal-marginal area broad light brown, behind the subterminal line with small lighter spots. Expanse of wings: 40 mm. Merida (Venezuela).

E. horriifer Schs. (81 g). Body above blackish-brown, beneath reddish-brown; forewing brown; in the basal two thirds powdered with black; veins black; a postmedian row of white vein-dots, the black subterminal line lunularly dentate. Hindwing brown with black veins, in the costal portion powdered with black and with traces of a double black postmedian line and a dark brown subterminal shadow. Expanse of wings: 36 mm. French Guiana.

E. melaina sp. n. (83 c) is an entirely sooty black species, in the basal two thirds of the forewing powdered with a deeper black, the darkest in the median area which is bordered by darker transverse lines being lighter on the averted sides; at the cell-end a light dot; the subterminal line is marked by the distally lighter powdering. Hindwing slightly lighter, behind the subterminal line which is only indicated by the contrast of the colours, likewise lighter. Described from the 1 ♂ without a habitat from the Berlin Museum.

E. tosticrista sp. n. (83 d). Forewing light reddish-brown as far as the posterior transverse line excepting an area behind the cell-end strewn with slate-colour, with blackish transverse lines, the anterior line dentate, the posterior line forming between the veins distally convex lunulae, receding at the cell-end; subterminal line composed of blackish wedge-shaped or angular streaks, being the thickest between 3 and 6, receding between 5 and 6. Hindwing reddish-brown, costally more whitish, strewn with slate-colour, transverse lines continuous to the anal margin and slightly angular in the centre, subterminal line distally bordered with light. Abdominal tuft on the 3 first rings very brightly contrasting chestnut-red. According to 1 ♂ from Rio de Janeiro from the Berlin Museum.

E. faeculenta sp. n. (83 d) is somewhat similar, smaller and more slender, forewing more greyish-brown, in the distal area lighter, with fine blackish veins, the blackish transverse lines of a similar shape as in *tosticrista*, but more interrupted, the subterminal line of smaller spots, forming small angles. On the similarly coloured hindwing only the subterminal line extends to the anal angle; dorsal tufts on the abdomen not contrastingly coloured. According to 1 ♂ from Mt. Tolima in the Berlin Museum.

E. vitripuncta Schs. (= *cloe* Drc.) (83 d) is light cinnamon reddish-brown, in the basal portion feebly darker, distally bordered by a fine light line being obtusely angled below the costal margin; a subterminal row of small whitish, feebly hyaline spots, the lower ones of which are inwardly feebly pupilled blackish. Hindwing with a subterminal row of whitish hyaline spots the 3rd of which, counted from the apex, is very large and inwardly removed almost as far as the cell-end, Venezuela.

E. fenestrata Dogn. is considerably smaller, the colouring more ochreous brownish-white, forewing strewn with brown, in the marginal area broadly strewn with lilac grey and white, besides the postmedian line there is also a whitish antemedian transverse line, the subterminal hyaline spots are more irregular, single spots receding somewhat; the blackish fringes are dotted white on the ends of the veins. Hindwing at the anal margin clothed with long white and pink hairs; subterminally only 3 small hyaline spots, two between 3 and 5, and a smaller one between 6 and 7; behind it before the margin small white lunular spots. Expanse of wings: 24 mm. São Paulo de Olivença (Amazons).

E. punctulata Dogn. Forewing light ochreous brown, in the costal half of the median area darker brown, with black transverse lines and discal spot; the antemedian line is double, the posterior line likewise dentate, with black and white vein-dots; instead of the subterminal line there is a row of black internerval dots which are inwardly removed between 5 and 6 and between 9 and 10; fringes black, on the ends of the veins ochreous. Hindwing light brown, costally ochreous with the beginning of a postmedian line, subterminal line as on the forewing, the dot between 5 and 6 extinct. Expanse of wings: 37—38 mm. Cañon del Tolima (Colombia).

E. punctigera Dogn. (83 d) is similar, less ochreous, darker brown, the transverse lines broken up into dots or small hazy spots, the postmedian line between 4 and 3 distally curved, the discal spot which in *punctulata* touches the antemedian inner line, is here situate farther outside; the subterminal area lighter, the round distinct subterminal dots surrounded by light, the dot between 9 and 10 is absent. Expanse of wings: 36 mm. Rio Songo (Bolivia), Venezuela.

E. ozora Drc. I only know this species from the brief description and from a photograph of the entirely damaged type kindly sent by Mr. TALBOT; judging from it, it seems to be slightly similar to the two pre-

ceding species. Ground-colour light brownish; a shadow-like antemedian transverse line and a similar postmedian one accompanied by darker vein-dots; the subterminal line being composed of conspicuous, blackish, small round spots recedes rectangularly between 5 and 6; the small spots seem to be situate in lighter rings. Hindwing much lighter, whitish, at the margin with very feeble spot-like darkenings between the veins. From Sarayacu (Ecuador).

maculata. **E. maculata** Dogn. (81 g). Body brown mixed with ochreous. Forewing blackish-brown, strewn with brownish ochreous, at the inner-margin more densely than at the costal margin; the 3 blackish-brown transverse lines die away more or less in the ground-colour, both the median ones being accompanied by white vein-dots; subterminal line lighter yellowish ochreous, distally receding below the costa and between 2 and 3. Hindwing rusty brown, in the costal area blackish-brown, behind the median line yellowish ochreous, and also behind the subterminal line. Expanse of wings: 39 mm. Yahuar Mayo (Peru).

tornipuncta. **E. tornipuncta** Schs. Head and thorax dark greyish-brown, abdomen light brown. Forewing dark brown, at the costal margin broadly strewn with grey, both the transverse lines marked by white vein-dots, at the cell-end a small dark spot, the dentate subterminal line is indistinctly darker and terminates at the inner angle in a white spot. Hindwing light brown, in the costal portion broad white strewn with blackish, whereby indistinct lines are produced. Expanse of wings: 35 mm. French Guiana.

necopina. **E. necopina** Dogn. (83 d) entirely resembles *tornipuncta*, but the white inner-marginal spot is absent; the costal area of the forewing is still more extensively whitish, also at the base white irroration. Peru, Colombia.

necopinella. **E. necopinella** Dogn. is allied to *necopina*, the brown thorax intermixed with white and yellowish hairs; forewing light brown, costally strewn with white, the base of the cell pure white, below it light yellowish, both the transverse lines whitish, dotted on the veins, the dentate subterminal line feeble; the fine dark veins terminate on the fringes in white dots. Hindwing white, in the larger anal-marginal portion light yellowish-red. Expanse of wings: 30 mm. French Guiana.

lascoria. **E. lascoria** Drc. (83 d) is rather variable in size and marking. Forewing wood-brown, costal margin broadly strewn with white, particularly in the basal half, below it densely scaled and haired blackish-brown; both the transverse lines are double, filled up with somewhat whitish, below the costal margin distally angular, the anterior line then dentate, mostly dying away in the dark irroration, the exterior line in its inner portion dentate, the outer portion more brownish, forming a slight distal bow from 5 to the inner margin; subterminal line very thick black, pointedly dentate, receding between 5 and 6 and between 3 and the inner margin. Hindwing light brown, in the costal portion whitish with several beginnings of lines and the strong subterminal line extending to the anal angle. Type from Sarayacu (Ecuador); also from Costa Rica. The distinctness of the black transverse lines and the denseness of the black inner-marginal irroration in the basal half varies exceedingly. — **cariacica** (Stgr. i. l.) f. n. (81 f), from the Rio Grande and Espiritu Santo (Brazil) is such a form being somewhat smaller, indistinctly marked, intensely and uniformly irrorated. Type in the Berlin Museum.

sulcata. **E. sulcata** Dogn. is very similar to *lascoria*; forewing light brown, the two first submedian thirds much darker brown with a purple gloss, containing 5 fine lilac white parallel lines; the antemedian line is only distinct at the costal margin, double, the outer portion extending through the cross-vein, behind it the costal margin is strewn with light; postmedian line strongly dentate, angular on 8, behind it from 5 to the costal margin white vein-streaks, subterminal line uniformly strongly dentate, receding a little on 5. Hindwing light brownish ochreous, in the abdominal half with coppery brown hair, with 2 dentate blackish-brown lines, the postmedian line short, the subterminal line as far as 3. French Guiana.

semita. **E. semita** Schs. (81 g). Anterior body grey, strewn with brown, mesothorax and abdomen above brownish-black, beneath light red-brown. Forewing in the costal portion grey; in the cell and below 4 brownish black, with still blacker veins, above 4 yellowish-red with a pink tint, strewn with black and with black veins, near the cell also strewn with white; from the costal margin to 5 a fine undulating dentate black subterminal line. Hindwing light brown, costally greyish brown, with an irregular darker subterminal line. Expanse of wings: 37 mm. French Guiana.

onesca. **E. onesca** Schs. Head and thorax blackish-brown, abdomen light brown with darker transverse bands. Forewing basally and below 4 blackish-brown, the rest light grey, scantily strewn with a darker colour, at the cell-end with a small dark spot, below it with a dark undulating line to the inner margin; from the costal margin to 6 with fine dark postmedian vein-streaks and a dentate dark subterminal line from the apex to 4, at the interior angle with a grey spot. Hindwing brown, at the costal and distal margins as far as 4 grey with darker irroration, a straight dark postmedian line and a dentate subterminal line. Expanse of wings: 40 mm. British Guiana.

vithersi. **E. vithersi** Schs. (83 e) is very similar to the two preceding species. Head reddish-brown, collar grey, thorax blackish, abdomen brown, above darker. Forewing dark grey, with black veins, costal margin and a large round spot at the cell-end light grey, the latter distally with velvety black vein-streaks, close behind it with the fine darker postmedian line; subterminal line only marked at the apex. Hindwing brown, in the costal portion light grey, here with a double median line, subterminal line black. Expanse of wings: 30 mm. French and Dutch Guiana.

E. barda Schs. is allied with *vithersi*. Anterior body brown mixed with black. Abdomen brown, *barda*, above darker. Forewing in the costal portion and in a postcellular spot whitish, the cell spotted black, otherwise dark grey, strewn with black and brown, with a black streak near the base of the cell; at the costal margin 3 oblique light brown lines are indicated; postmedian line double, the interior portion from the costal margin to 4 intensely dark velvety brown; distal margin broad lighter and browner with the very irregular blackish subterminal line, behind it with dark brown veins. Hindwing costally greyish white, inside light brown, subterminal line interrupted, the short postmedian line double. Expanse of wings: 38 mm. Costa Rica.

E. bardina Dogn. (81 g) is very similar to *barda*; body reddish-yellow, abdomen above red-brown, *bardina*. Forewing light brown, with black veins, in the basal half of the costal margin whitish, also behind the cell as far as 4; basal area in the centre blackened as far as the antemedian line which is angular on 4; postmedian line angular on 7, almost straight, only below 4 feebly undulating, with white vein-dots, outside accompanied by a light indistinct line; subterminal line deeply dentate, receding from 6 to 4 and below 3; fringes on the ends of the veins speckled with white. Hindwing yellowish-red, in the costal portion white, traversed by fine black lines, subterminal line almost to the anal angle. 37 to 38 mm. Rio Songo (Bolivia).

E. medioclara Schs. (81 g). Head yellowish reddish-brown, thorax blackish mixed with violettish *medioclara*, grey, abdomen reddish-brown, above darker. Forewing basally and at the distal margin light brown; in the centre of the inner margin a broad light lilac area, at the cell-end a large white area containing a black spot, blackish shadow-like antemedian and postmedian bands are confluent between the white and lilac area; the black subterminal line is dentate. Hindwing light brown, in the costal portion broadly black strewn with lilac, apically turning whitish, with a dark subterminal line. Expanse of wings: 39 mm. French Guiana.

E. tamila Schs. (83 e). Head and collar light grey, thorax blackish, abdomen dark greyish-brown, *tamila*. Forewing light yellowish-red, below the cell and 4 shaded with dark brown, with a large light grey spot in the centre of the inner margin, before which there is a velvety black rudiment of the antemedian line; veins, excepting the costal ones, striped black, at the cross-vein two black dots, behind them a fine brown double postmedian shadow; subterminal line receding somewhat between 5 and 6. Hindwing in the interior half light brown, in the costal portion light grey, scantily strewn with black, with a black, partly double median line being dotted on the veins, and a dark subterminal line. Expanse of wings: 39 mm. French Guiana.

E. signifera Dogn. (♀ = *tomisigna* Dogn.) (81 g). Body and wings dark brown, forewing with *signifera*, black irroration at the costal margin and in the cell before the centre; postmedian line very feebly marked with light dots on the veins, beginning with dark costal spots just like the subterminal line which is composed of small, distally light internerval lunulae, at the anal angle a larger one. In the ♂ along the inner margin a fine white double streak from the base of the cell to the margin above the inner-marginal vein and rectangularly to it near the base of the inner margin another one to the inner margin; from the centre of the double streak mentioned first another single streak extends to the inner margin. Hindwing lighter brown with traces of a subterminal line. Expanse of wings: ♂ 30, ♀ 40 mm. Peru.

E. albiochrea Kaye is grey on the head and thorax with yellowish ochreous hairs. Forewing light *albichrea*, brown, strewn with grey, with a black basal streak and above it an irregular grey spot which is outside bordered at the costal margin by 2 short curved lines; transverse lines very indistinct, fine, the veins somewhat darker. Hindwing in the costal third whitish-grey with the beginnings of 2 or 3 lines, the two anal-marginal thirds reddish-brown, at the margin lighter. Abdomen reddish-brown, dorsal tufts blackish. Expanse of wings: 42 mm. Trinidad.

E. cinerea Dogn. Forewing monotonously ashy grey, without any marking, only in a certain light *cinerea*, there are very feeble traces of transverse lines and of a discal spot; hindwing in the costal portion as on forewing, otherwise somewhat browner with traces of a subterminal line. Meida (Venezuela).

E. iresca Schs. (81 h). Anterior body and forewing as well as the costal portion of the hindwing grey, *iresca*, rather densely strewn with brown; on the forewing the brown transverse lines are finely dentate, at the cell-end a fine brown streak; subterminal line incurved between 4 and 6. Abdomen and hindwing light brown, the hindwing with traces of darker lines at the costal margin and a feeble undulating subterminal line. Expanse of wings: 36 mm. Dutch Guiana.

E. vistorica Schs. (81 h). Anterior body and forewing wood-brown, strewn with whitish, in the basal *vistorica*, area liver-brown, in the median area the scales are erect; veins and inner margin narrowly yellowish-reddish, strewn with brown, both the transverse lines are whitish, fine, feebly marked, the subterminal line composed of whitish, inside dark-spotted lunae. Hindwing dark brown, in the costal portion as on the forewing with a white short postmedian line and a white undulating subterminal line which is spotted in the costal-marginal portion. Expanse of wings: 39 mm. Described from 1 ♂ from Las Quigas, Venezuela. Larger than the very closely allied *fusconigra* Dogn. which lacks the postmedian line beneath.

E. fusconigra Dogn. is above blackish-brown, strewn with white, with a darker discal spot and feeble *fusconigra*, white vein-dots instead of the two transverse lines, the light subterminal line receding between 4 and 6. Hindwing rusty brown, in the costal portion like on the forewing with an apically white-spotted subterminal line. Beneath

rusty brown with traces of the light subterminal line. Anterior body blackish-brown, abdomen rusty brown with 2 intense red dorsal tufts. Expanse of wings: 35 mm. French Guiana.

- funerea.* **E. funerea** Schs. (81 h). Head and thorax dark grey, strewn with white, abdomen brown. Forewing and costal portion of hindwing dark brown, finely and densely strewn with grey; shadow-like indistinct traces of the transverse lines and subterminal line, the rest of the hindwing brown. Expanse of wings: 47 mm. São Paulo (South-Eastern Brazil).
- deformis.* **E. deformis** Schs. Forewing above brown with a large round black cellular spot and a series of small black spots along the distal margin, which are the largest and most distinct at the anal angle and are smaller towards the apex. Hindwing brown, in the costal-marginal area lighter with a few small black spots near the apex. Expanse of wings: 36 mm. A smaller species, according to 1 ♀ from Paso de San Juan, Veracruz, Mexico.
- naraxa.* **E. naraxa** Schs. (83 e). Body greyish-brown, base of abdomen darker. Forewing brown, particularly at the costal margin and in the median area strewn with whitish, with finely dentate blackish transverse lines, the anterior one double, filled with whitish, the posterior line single with grey vein-dots, between both a black cellular dot; the dark subterminal line recedes between 4 and 6. Hindwing light brown, in the costal portion whitish-grey with a dark grey undulating subterminal line. Castro, Paraná.
- narceta.* **E. narceta** Schs. (83 e). Anterior body and forewing grey, strewn with brown, forewing with an indistinct dark spot at the cell-end and traces of two transverse lines and a white postmedian spot at the costal margin; the dark subterminal line is fine, behind it somewhat darker vein-streaks, the dark grey fringes feebly speckled with yellowish-red. Abdomen and hindwing brown, the latter in the costal-marginal area grey with a dark subterminal line. In the ♀ the postmedian line is more distinct as a white line, the subterminal line being less distinct. Castro; Rio de Janeiro (Brazil).
- nocens.* **E. nocens** H.-S. (83 e). The type of this species which has been mistaken for a long time, as well as another specimen, are from the Berlin Museum. The ♂ is very similar to *narceta*, smaller, much less strewn, lighter yellowish-brown, the antemedian line indistinctly double, subcostally and on the median receding acute-angularly, the postmedian line subcostally produced very far towards the margin in 2 long dents, outside bordered with light; the subterminal line is composed of small dark sagittary spots, behind it the marginal area is decidedly darkened; fringes speckled. Hindwing red-brown, in the costal-marginal portion yellowish-grey with a distinct subterminal line and a dark median shadow. Brazil.
- lignosa.* **E. lignosa** Wkr. (83 e) is likewise very closely allied to *narceta*, larger, the ground-colour whitish, strewn with light brown, in spite of the strewn particularly towards the margin somewhat glossy, at the cell-end an indistinct darker angular streak; transverse lines of ♂ distinctly somewhat dentate, on the averted sides bordered with white, in the ♀ very indistinct, the white more prominent, the subterminal line divided into very feeble, darker, small spots, in the ♀ almost absent; fringes not speckled. Brazil (Rio de Janeiro).
- schadei.* **E. schadei** Schs. Anterior body mouse-coloured, mixed with brownish olive. Abdomen sand-coloured brownish. Forewing light drab, finely strewn with olive brown, in the basal third somewhat strewn with blackish, with smoky blackish transverse lines, the subterminal line divided into small spots, receding on 5, below it somewhat dentate. Hindwing in the interior portion sand-coloured brownish with a black median line from the costal margin to the lower cell-angle and a fine subterminal line. Expanse of wings: ♀ 54 mm. Villarica (Paraguay).
- mollis.* **E. mollis** Sepp (81 h) is allied to *narceta* and *lignosa* from which it differs in more distinct undulating blackish transverse lines and above all in the basal area being darkened by blackish, only the costal-marginal portion being strewn with a lighter colour; the postmedian line is double at the costal margin, where it is filled with a somewhat lighter colour. Abdomen and hindwing pinkish brownish, the postmedian line extends almost to the lower cell-angle, the dentate subterminal line not as far as the anal angle. Surinam. The larva, according to SEPP, is rosy red with a yellowish lateral stripe being above shaded with dark brown, with fine white hairs. It lives on *Anona muricata* and changes into a brownish pupa.
- grammophora.* **E. grammophora** Fldr. (81 h) I do not know. The figure shows a cinnamon brownish body and wings, the forewing costally in the median area broadly lighter flesh-coloured; transverse lines fine, blackish, at the costal margin thicker, on the averted sides bordered with light, the posterior line angular below the costal margin; subterminal line whitish; also on the hindwing three feebly darker, outside lighter transverse lines are visible, extending almost to the anal margin. Brazil.
- elongata.* **E. elongata** Dogn. (81 h). This species described from 1 ♀ shows very long, almost oval forewings: above brown, hindwing somewhat lighter and more yellowish; forewing with a submedian black basal streak and a large oval spot filled with light, the base of it on the cross-vein, the end of it at the margin on vein 6, the posterior double transverse line is only indicated at the costal margin, the subterminal line is dentate; distal margin somewhat lighter, undulating, the fringes between the veins blackish. Hindwing with a median line extending to the disc, and a dentate subterminal line. Loja (Ecuador).

E. roseimaculata Dogn. (81 h). Forewing above reddish blackish-grey, the course of both the transverse lines marked by white vein dots, in each angle of the cross-vein with a black dot; two subterminal light reddish spots between 5 and 7, outside bordered with black, the ends of the veins white. Hindwing and abdomen blackish. Cali (Colombia). *roseimaculata*.

E. nardina Dogn. (81 h). Body and wings dark chestnut brown, in the median area lighter and towards the margin turning light yellowish-brown, the colours distinctly separated, but without a separating line; at the cell-end a dark streak, behind it a feebly convex line distally slightly strewn with white; subterminal line twice angular, composed of small black spots. Hindwing chestnut-brown, in the costal portion darker with the beginnings of two transverse lines. Yahuar Mayo (Peru). *nardina*.

E. scaptia Dogn. (81 i) is a very small species, the ♂ with an expanse of but 25 mm. Above dark brown, the two double transverse lines only marked by scattered whitish atoms, at the cell-end a darker dot; subterminal line composed of black lunulae distally bordered with white and inwardly removed between 5 and 6, as well as 9 and 10; fringe with white dots on the ends of the veins. Hindwing somewhat lighter brown, in the costal-marginal portion darker, the subterminal line strewn with white. Lino, Panama. *scaptia*.

E. skaptiodes Dogn. is still smaller, above reddish-brown, basally darker; two rows of white vein-dots instead of the lines enclose a somewhat darker median area; a subterminal dark undulating line, outside bordered with a lighter colour, veins somewhat darker, on the fringes light. Hindwing lighter brown, in the costal-marginal portion darker with the beginnings of two distally lighter lines, the subterminal line as far as the anal angle. On the whole darker and more contrasting than *scaptia*. From the Rio Madeira (Amazons), taken in July, August. *skaptiodes*.

E. incopiosa Dogn. (81 i). Above light brown, thorax and base of the wings somewhat darker, distal area and hindwing lighter; transverse lines somewhat darker, feebly undulatingly dentate, without a discal spot, behind the postmedian line with a shadow; followed by two more, partly indistinct lines. On the hindwing with two somewhat whitish-strewn lines, the subterminal line almost to the anal angle. Expanse of wings: 28 mm. According to 1 ♂ from the Rio Hingu (Amazons). *incopiosa*.

E. rages Drc. Above very light reddish yellowish-brown, the veins somewhat darker, also the basal half somewhat more strewn with dark, with faint traces of a postmedian line being angular below the costal margin, and a subterminal line composed of lighter lunae, inwardly very feebly shaded with a darker colour. Hindwing still lighter brownish, only in the costal portion feebly strewn with a darker colour. Amazons. *rages*.

E. corcyra Drc. (82 f) is smaller than *rages*, loam-coloured brownish, in the basal half somewhat darker with feebly darker transverse lines and discal streak, the postmedian area as far as the grey shaded subterminal line lighter with a darker shadow-like band in it, receding between 4 and 6. Abdomen and hindwing lighter, at the costal margin darkened, the subterminal line not quite reaching the anal angle. From the Chiriqui (Panama). *corcyra*.

E. ragesina sp. n. (83 f) is somewhat similar to *rages*; forewing light reddish-brown, strewn with black, without any marking except a very indistinct postmedian line which is angular on 6 and behind which the strewing is slightly scantier. Hindwing only with traces of a subterminal line. Type: 1 ♀ from Venezuela in the Berlin Museum. *ragesina*.

E. libella Dogn. (81 i). Body above brown, beneath yellowish ochreous; forewing brown, in the distal half lighter with 2 quite indistinct transverse lines and a subterminal line of internerval dots, being strongly incurved between 5 and 7; the transverse lines are accompanied by faint whitish strewing, particularly the subterminal line; fringes brown, speckled with light. The brown hindwing shows in the distal costal half three dentate white lines, the two outer ones of which enclose a black subterminal line. Expanse of wings: 33 mm. Described from 1 ♂ from French Guiana. *libella*.

E. magnaevia Dogn. (81 i). Reddish yellowish-brown, head and collar reddish ochreous; basal half of forewing somewhat lighter, the interior half of the hindwing and the body monotonously brown. Forewing with a large black discal dot and double dentate blackish transverse lines, the subterminal line parallel to the postmedian line; the blackish margin is undulatingly dentate, on the veins interrupted by light. Hindwing with a short median line and a dentate subterminal line. According to 1 ♀ from Chanchamayo (Peru). *magnaevia*.

E. melancholica Btlr. (= *perosa* Dogn.) (83 f). Forewing on the light brownish ground densely scaled blackish-brown, only feebly strewn with whitish, feebly darker transverse lines marked by white vein-dots, the subterminal line by small black internerval spots; the ends of the veins before the fringes with one white dot each. Hindwing reddish-brown, in the costal portion like the forewing with white-dotted lines. Widely distributed and common from Mexico to Brazil. *melancholica*.

E. rapina Dogn. is allied to *melancholica*. Forewing light yellowish-brown, thorax and abdominal dorsum somewhat darker; the transverse lines similar as in *melancholica* marked by white vein-dots, the anterior line double, the posterior line only at the costal margin. Fringes brown and white; in the costal portion of the hindwing there are three yellowish-white dentate lines. Expanse of wings: 33 mm. Described from 1 ♂ from São Paulo de Olivença. *rapina*.

- amathuria*. **E. amathuria** Drc. is similar to *melancholica*, lighter, more reddish, distinguished by a very large roundish black discal spot; the postmedian line is composed of more contiguous white lunae, the veins before and behind it black, particularly towards the inner margin, and the subterminal line composed of small black wedge-shaped spots; the white dots before the fringes are absent, the fringes speckled dark and light. Costa Rica; Sarayacu (Ecuador).
- cassida*. **E. cassida** Dogn. (81 i). Body reddish yellowish-grey, abdomen above blackish. Forewing yellowish earth-coloured, strewn with white, with blackish-brown transverse lines, the antemedian line thick, double, regularly dentate, — the basal portion before it is somewhat darker — the double postmedian line strongly angular on 6, the interior part distinct and dentate, the exterior part hazy and straight, between both strewn with white; subterminal line dentate, incurved between 4 and 6, the veins behind it black. Hindwing in the anal portion reddish yellowish-brown, the subterminal line only distinct as far as 6. Rio Songo (Bolivia).
- alumnata*. **E. alumnata** Dogn. resembles *amathuria*, but it has no discal spot. Forewing brown, in the basal half and subcostally darker, veins and transverse lines darker, blackish-brown, the latter with white vein-dots, the subterminal line with short dents; from 6 to the inner margin the subterminal area is strewn with dark brown; the ends of the veins on the fringes light. Hindwing brown, in the costal portion darker with a complete dentate subterminal line. Expanse of wings: 41 mm. Loja, Ecuador, described from 1 ♂.
- distincta*. **E. distincta** Btlr. is above uniformly light reddish-brown, the lines similarly arranged as in the preceding species, but without the white vein-dots and very well distinguished by a large black spot at the base of the forewing. From the Rio Juruá (Amazons).
- putrida*. **E. putrida** Schs. (83 f). Body blackish brown with reddish brown dorsal tufts on the base of the abdomen; on the forewing the base and the inner-marginal area below 5 dull blackish-brown, the rest dull velvety brown, at the base a white dot; the antemedian line is on both sides bordered with a brownish sand-colour; at the cross-vein 2 black dots; the postmedian line is dark in the light costal-marginal portion, in the dark interior area of a light brown sand-colour; the spotted subterminal line recedes far between 5 and 6; veins in the marginal area light. Hindwing blackish-brown with irregular dark median and subterminal lines. From French Guiana.
- circumducta*. **E. circumducta** Dogn. (81 i). Yellowish-brown, hair on the head and thorax with white tips; base and costal margin of forewing lighter, the veins partly black; a thick oblique black antemedian band, close behind it at the cell-end an angular streak; posterior transverse line similar as the anterior band, appearing double by a shadow following behind it; a dentate blackish subterminal shadow; ends of the veins on the fringes white. Hindwing in the anterior costal half yellowish, distally blackish with a dentate subterminal line. Villavicencio (Colombia).
- juliana*. **E. juliana** Schs. is larger than the following *giulia* with more indistinct transverse lines on the forewing; above dark blackish-grey, with a feeble brown tint; hind tarsi whitish. Forewing above with a black spot at the cell-end, the fine dark transverse lines at the costal margin bordered with yellowish-red, the posterior line also at the inner margin; a similar light shadow at the anal angle. Hindwing greyish white with fine dark grey veins, at the costal and anal margins broad dark grey with a brown tint, with a lighter postmedian shadow. Expanse of wings: 42 mm. Costa Rica.
- giulia*. **E. giulia** Schs. (83 f) is dark greyish-brown on the body and forewing; the forewing with a black spot at the cell-end, and darker postmedian and subterminal bands which are fused below 3. Hindwing brownish greyish-white, costal and anal margins and fringes dark greyish brown. Expanse of wings: 38 mm. French Guiana.
- morens*. **E. morens** Schs. (83 f) is larger than the preceding species, the colour dull black with 2 velvety black dots in the cell-angles and feeble traces of postmedian and subterminal lines which are not fused below. Hindwing in the disc white, costal and anal margins broad, distal margin narrow black. French Guiana.
- roxana*. **E. roxana** Schs. (81 i). Head and collar yellowish whitish-grey, thorax blackish-brown, abdomen light brown with a darker basal tuft. Forewing light yellowish-grey, scantily strewn with brown with blackish-brown streaks at the base of the costal margin, below the base of the cell, and at the inner margin as far as the postmedian line which is fine, undulatingly dentate, brown, indistinct, and with a large blackish-brown cellular spot; subapically at the costal margin a dark brown shadow; distal-marginal veins with fine black stripes; fringes speckled with brown. Hindwing light brown, at the apex yellowish greyish-white with a dark brownish-grey irregular subterminal shadow, fringes on the ends of the veins dotted white. Expanse of wings: 33 mm. French Guiana.
- salandria*. **E. salandria** Schs. is smaller than the similar *roxana*. Head and collar grey, thorax blackish-brown, abdomen brown. Forewing grey, strewn with brown, with a faint dark cellular spot and a brown subapical spot at the costal margin, and another one in the centre of the inner margin; the finely dentate transverse lines are double, the brown submarginal line is undulating, the veins behind it black; between 3 and 4 near the cell a brown shadow. Hindwing similar, in the disc and at the anal margin light brown. Expanse of wings: 31 mm. Dutch Guiana.
- propinqua*. **E. propinqua** Wkr. is unknown to me. The ♂ is described to be yellowish reddish-brown, on the meta-thorax grey. Forewing whitish, densely strewn with yellowish-red and rusty brown, with an unstrewn antemedian

transverse band, the interior side of which is bordered by a blackish line, behind the centre with two indistinct, darker yellowish-red, notched lines, one of which is postmedian, the other subterminal. Hindwing in the costal portion whitish, densely strewn with yellowish-red. Expanse of wings: 18 lines. Bogotá (Colombia).

E. marna Schs. (83 g) is an unmistakable species, forewing on the yellowish-white ground densely strewn with reddish-brown and blackish, with a somewhat darker shaded discal spot and a broad steel-grey inner margin which extends subterminally up to vein 4, in the marginal area with 4 undulating reddish-yellow transverse stripes, interrupted by the light veins, the second before the margin darker brown or blackened, often also visible in the steel-grey area as far as the inner margin. Hindwing cinnamon-red, in the costal portion coloured like the forewing. Widely distributed in Brazil. *marna*.

E. vittabunda Dyar exhibits the colours of *marna*, but the marking rather of *lankesteri*: thorax and inner margin of forewing violettish-brown, the rest of the wing loam-coloured brown, strewn with red-brown, with the 4 transverse lines of *marna*. Hindwing suffused with reddish-brown, at the costal margin with the beginning of brownish loam-coloured lines. Expanse of wings: 36 mm. Panama. *vittabunda*.

E. namora Schs. (83 g). Body above light lichen-coloured grey, beneath yellowish. Forewing brown, strewn with black, inner and distal margins as far as 4 light lichen-coloured; the darker brown postmedian line is distally bordered by yellowish reddish, from the costal margin feebly curved as far as 4, then undulating and extending above the submedian line to the base; a series of darker brown subterminal spots is distally bordered with yellowish-red as far as 4, below 4 there is a larger brown spot and below it another smaller one farther towards the base; an undulating yellowish-red limbal line is distally shaded with dark grey. Hindwing light red-brown, at the costal margin darker brown with traces of yellowish-red lines. Expanse of wings: 31 mm. French Guiana. *namora*.

E. lankesteri Schs. (83 g). Forewing yellowish-red, densely strewn with dark brown, inner and distal margins as far as 4 like the thorax light grey, upwards in the basal half bordered with white, distally more dark brown, spotted; above 4 with a subterminal row of small brown spots which are outside bordered with yellowish-red. Hindwing light brown, with a slightly darker median shadow and behind it the beginnings of yellowish-red lines; fringes spotted grey. Costa Rica. *lankesteri*.

E. thyatira Drc. (= *albiplaga* Schs.) (83 g). Body creamy white, only the head and palpi brownish. Forewing brown with large creamy spots at the costal margin, apex and inner-margin, the latter spots being connected. Hindwing in the disc light brown, a large quadrangular apical spot, the inner and distal margins narrow yellowish-white. The type originates from the Chiriqui, Panama; Costa Rica. — **taminata** f. n. (83 h) is a form from Colombia (Villavicencio), which is not rare and very much darkened. Abdomen, excepting the anal hair, dark brown, on the forewing the apical spot is smaller, the two small costal-marginal spots are almost entirely absent, hindwing nearly quite blackish-brown. The grey larva with broad black lateral bands, according to FASSL, resembles a wood-louse, on touching the leaf it raises its anterior and posterior ends. Pupa in a yellow web which is intensely powdered with white. *thyatira*.

E. cariosa Schs. Body brown, collar and patagia outside white. Forewing at the inner margin below the submedian, at the distal margin, and postmedianly below 4, besides in a preapical spot at the costal margin light brown, the rest greyish-white, strewn with brown; the postmedian line is accompanied by white vein-dots from 5 to the inner margin; the subterminal line is composed of small brown spots which are bordered with white below 4. Hindwing brown, costal portion and postmedian area behind the cell white, scantily strewn with brown. Expanse of wings: 35 mm. Costa Rica. *cariosa*.

E. braganza Schs. (83 h) is whitish on the forewing, on the head, collar and shoulders, whilst on the inner margin and three quarters of the distal margin inclusive of an inner-marginal third of the postmedian area and of a subapical spot at the costal margin it is light brown. Hindwing brown, at the costal margin almost to the apex white. The ♀ is larger and lighter, the white colour particularly on the hindwing more extensive. Colombia, Brazil, Ecuador, apparently not rare. — f. **sordida** Dogn. is a somewhat smaller form from French Guiana in which the white colour turns dingy yellowish, the spots not being distinctly defined, smaller and darker brown. *braganza*.

E. branzoides Schs. is very similar to *braganza*, the collar only laterally white, the forewing more marked, above the cell strewn with brown, with double, partly interrupted, brown transverse lines, and 2 dark dots in the cell-angles, the subterminal brown crescents distinct. Fringes brown with white dots on the ends of the veins; also on the forewing the white costal-marginal area is strewn with brown and crossed by brown lines. Costa Rica. *branzoides*.

E. spurcata sp. n. (83 h) is very similar to the two preceding species, but with much narrower and more pointed wings. Forewing greyish-white, with fine black veins, scantily strewn with black, predominantly in the discal area, the brown marking as in *braganza*, but much lighter and narrower, but at the distal margin up to the apex; the postmedian line only visible from the inner margin to 4, with fine black vein-dots, the subterminal lunae inwardly shaded with grey, outside broadly bordered with white. Hindwing light reddish-brown, strewn with black, at the costal margin whitish with a double postmedian line and a subterminal line which

is outside bordered with white. Body, also head and collar brown. According to an unlabelled ♂ from the Coll. WEYMER in the Berlin Museum.

obliterata. **E. obliterata** Schs. (83 h) is the most closely allied to *braganzoides*, but the ground-colour is a soft slate-colour strewn with red-brown; the brown spots are similarly arranged as in the preceding species, of a more Pompeian red colour, with distinct, double transverse lines, the two cellular dots distinctly black, the distinct subterminal lunae blackish grey, receding far between 4 and 6, then again below 4. Costa Rica; French Guiana; Brazil (Pará).

ampira. **E. ampira** Drc. (♀ = *pira* Drc.) (83 h, i). Body dark red-brown, patagia mixed with white. Forewing white, strewn with black, basally, in the basal half of the inner margin, at the distal margin as far as beyond 6, subapically at the costal margin, and in an irregular subterminal spot between 2 and 4 deep red-brown, between the indistinctly double black transverse lines with 2 black discal dots, the subterminal line undulatingly dentate; fringes between the veins spotted black. Hindwing lighter brown, in the costal-marginal portion white strewn with black, and blackish transverse lines. The ♀ is much darker, the deep red-brown colour more extensive, and the black irroration much denser. Ecuador, Amazons, Peru.

vecina. **E. vecina** Schs. Head and thorax dark brown, at the patagia somewhat grey, abdomen light red-brown. Forewing greyish-brown, strewn with brown, inner and distal margins as far as beyond 5 lighter and purer brown; the undulating antemedian line is united in a round bow with the oblique postmedian line above the submedian; discal spots absent, near the apex a light brown costal spot. Hindwing light red-brown, costal portion greyish-brown as far as the dark subterminal line. Expanse of wings: 33 mm. Cayenne, French Guiana.

rundala. **E. rundala** Schs. (83 i). Body brown; forewing steel-grey, inner and distal margins as far as 7 brown, an oblong subapical spot at the costal margin also brown; a quadrangular dark brown spot near the base of the costal margin before the double grey antemedian line, which is filled with brown; at the cell-end 2 black dots; the double light grey postmedian line is acute-angular below the costal margin, between 3 and 4 a brown spot which interrupts it; subterminal line interrupted, distally shaded with steel-grey. Hindwing brown, at the costal margin broad light steel-grey as far as the subterminal line, traversed by darker lines. Costa Rica; French Guiana.

laronia. **E. laronia** Drc. (83 i) is somewhat similar, more slender, the distal margin of the forewing more oblique, without any brown at the inner margin, lactean, the brown subbasal spot at the costal margin not darker, cellular veins fine black, at the cell-end a brown spot inside finely bordered with black; the white postmedian line is still more acutely angled, the dent extends almost to the margin, the subterminal line in the lower half notched. Hindwing darker, the subterminal line as far as the anal angle inwardly shaded with dark grey. Costa Rica, Panama.

laudia. **E. laudia** Drc. (= *laudissima* Dyar) (83 i). Forewing very dark brown, in the basal third of the costal margin the darkest, at the costal margin yellowish-white, also the two transverse lines which are close together, almost contiguous below the cell, and below the costal margin connected by a similarly coloured streak; veins partly yellowish-white, also the fine subterminal line. Hindwing with several yellowish-white beginnings of lines in the apical third of the costal margin. Panama to Ecuador and British Guiana.

cercina. **E. cercina** Drc. (83 i) is very similar to *laudia*; it is smaller, with rounder wings, forewing somewhat lighter brown, the white lines somewhat more parallel, between them a black discal spot, the costal margin not white. Hindwing more red-brown. Honduras.

charax. **E. charax** Drc. (83 i) is still smaller. Forewing lighter greyish-brown with a thick black discal spot, anterior transverse line not white, fine black irregular, posterior line outside bordered with white, above the inner margin double, representing 2 white parallel streaks obliquely extending distad; subterminal line composed of small black spots outside broadly bordered with white. Hindwing in the larger anal-marginal portion red-brown, in the grey costal-marginal portion with 2 white parallel streaks obliquely extending inwards; subterminal line as on forewing. Panama.

flatura. **E. flatura** Dogn. is much lighter than *charax*; body and forewing light yellowish-grey with a black, light-centred discal dot and indistinct darker transverse lines; the regular subterminal line is parallel to the margin and outside accompanied by whitish lunulae. Abdomen and hindwing light reddish-brown, in the costal-marginal portion coloured like the forewing, with short beginnings of lines in it. Expanse of wings: 34 mm. Venezuela.

serapion. **E. serapion** Schs. (83 i). Anterior body and forewing brown mixed with olive-grey, as far as the postmedian line strewn with blackish-brown, both the transverse lines, the anterior line only partly indicated by white vein-streaks, at the cell-end a small black spot; subterminal line composed of small dark spots, veins in the marginal area brown strewn with white. Abdomen and hindwing brownish sand-coloured, hindwing in the costal-marginal portion with darker shadowy bands and single white vein-dots. Distal margin finely undulatingly dentate. Costa Rica.

tanta. **E. tanta** sp. n. (83 i). Forewing olive-brown, in the median area slightly darker, edged by black transverse lines, before the antemedian line with a curved white band which is crossed by a second black line, the postmedian line composed of small black spots, which are outside bordered with white; at the cell-end a feeble

blackish spot; subterminal line composed of black roundish spots which are distally white-pupilled particularly in the apical half. Hindwing in the anal-marginal portion olive-grey with the beginnings of blackish, distally white-edged lines, subterminal line as far as 5 intense and broad, then finer. Fringes olive-blackish speckled with white. According to 1 ♂ from South Brazil in the Berlin Museum.

E. murina *Möschl.* is unknown to me. Forewing ashy grey, in the basal area excepting the red-brown *murina*, costal margin yellowish-grey, distally bordered by a dark brown arcuate stripe which is interrupted towards the costal margin and inner margin; at the cell-end an oval dark brown spot; the curved postmedian line is undulating, brown; subterminally at the costal margin and between 4 and 6 one red-brown spot each, behind it an arcuate row of red-brown indistinct small spots. Hindwing with the beginning of an indistinct red-brown antemedian line and a similar subterminal line as far as the anal margin. Expanse of wings: 44 mm. Surinam.

E. bochica *Schs.* (81 i). Forewing light grey, at the base brown with 2 coherent undulating antemedian *bochica*, transverse lines, at the cell-end a black spot, behind the cell another double transverse line and a subterminal row of brown spots; subapically at the costal margin a brown spot, the distal margin excepting the apex and anal angle brown. On the hindwing the costal and distal margins grey, the anal margin and disc brown with 2 undulating brown transverse lines. Expanse of wings: 38 mm. Peru.

E. audifax *Schs.* (85 g) as well as the two preceding species belong to the very large *ogenes*-group. Body *audifax*, light sand-coloured grey with a chestnut brown spot on the metathorax; forewing whitish, at the base densely strewn with chestnut-brown, bordered by a fine line which is inwardly angled below the cell; at the cell-end a brownish-black spot, the postmedian area between 3 and the costal margin suffused with grey sand-colour; posterior transverse line double with brownish scales, behind it at the costal margin a small square red-brown spot, and a similar double spot between 4 and 6 as an intersecting portion of the smaller subterminal spots; distal margin excepting apex and anal angle powdered with cinnamon brownish. Hindwing cinnamon brownish, the apical half of the costal margin, apex, and distal margin white with an angular subterminal line. Expanse of wings: 32 mm. Callao (Peru).

E. cinifax *sp. n.* (84 a). Body brownish, anterior body more mixed with grey; forewing whitish, *cinifax*, basally greyish-brown, the cross-vein hardly darker, the median area particularly towards the margin powdered with a light brownish grey, bordered by the feebly darker postmedian line which recedes very far on 5 and is very far produced on 4 and 8 to 10; subterminal line receding between 4 and 6, inwardly shaded by grey sand-colour, fringes speckled black and white. Hindwing light brown, basally defined by a darker greyish brown antemedian line which extends almost to the anal angle, and white behind the very irregular subterminal line which recedes far between 4 and 6 and comes close to the margin between 3 and 4, as well as 6 and 7; fringes as on forewing. Type: 1 ♂ from the Rio Songo (Bolivia), in the Berlin Museum.

E. palota *Schs.* (84 a) is very similar to *cinifax*, larger, purer white, body and basal area on both *palota*, wings blackish-brown, on the forewing the postmedian line extends after the angle below the costal margin almost straight and vertical to the inner margin, with fine black vein-dots; subterminal line quite indistinct; the distal half of the median area and the marginal area feebly shaded with grey. Hindwing in the anal-marginal portion broadly covered with brown hairs, the subterminal line inside shaded with a brownish grey. Brazil (Castro, Sa. Catharina). — **songoensis** *f. n.* (84 a), from the Rio Songo (Bolivia), still more approximates *songoensis*, *cinifax*, especially by the shape of the postmedian line which forms 2 similar projections, the subterminal line is more distinct, the hindwing greyer, the anterior body whitish.

E. albofusca *Dogn.* is allied to *palota* from which it only differs in the more scantily black-scaled *albofusca*, basal area which is therefore coloured like the rest of the wing and hardly darker; postmedian and subterminal lines dentately marked by dark scales. Hindwing light brown, in the costal portion white strewn with black, enclosing the short postmedian line; subterminal line broad and parallel to the distal margin, the white fringe slightly strewn with black. Expanse of wings: 43 mm. South-Eastern Peru.

E. albata *Dogn.* (85 g) probably represents *albofusca* in the Amazon District. Body white with a *albata*, few black hairs, at the base of the abdomen light reddish yellowish-brown; forewing white, very scantily strewn with black at the base, a black discal dot and faint black transverse lines, antemedian line double, posterior line also double, subterminal line only at the costal margin, below it projecting farther towards the margin, angular on 5; marginal veins fine black. Hindwing in the abdominal half light yellowish-red, in the white costal portion with the beginnings of the lines. Expanse of wings: 34 mm. São Paulo de Olivença.

E. semifunebris *Schs.* (84 a) is very similar to *palota*, the blackish-brown basal area is much more *semifune-* extensive, at the cell-end there are 2 black dots or an angular streak; postmedian line almost as in *palota*, *bris*, subterminal line composed of small black sagittary spots which recede far between 4 and 6; fringes less speckled. Widely distributed in Brazil.

E. ogenes *H.-Schöff.* (84 a) is similar to the preceding species, the white surface is more irregularly *ogenes*, strewn with brown, the blackish-brown basal area strewn with white, at the cell-end with a thick black spot, close behind it the sometimes distinctly double postmedian line strewn with brown; the small subterminal sagittary spots are very long at the costal margin, at the inner margin and between 4 and 6 stronger,

the margin behind it broadly shaded with a brownish grey. Hindwing extensively light brown. in the costal portion greyish white, with a dark antemedian line and an irregular subterminal line. Brazil.

genesæ. **E. genesæ** Schs. (84 a) is very similar, with longer wings, duller, the basal portion, body, and hindwing brownish-grey, the white colour not so irregularly strewn, powdered more with a grey sand-colour, the discal spot dull, postmedian line very distinctly double, subterminal line less strong, nearer to the margin, its 2 costal spots very long. Hindwing in the apical half of the costal margin white, the subterminal line recedes very far inwards between 5 and 6. Brazil (Castro; São Paulo).

victoris. **E. victoris** Dogn. (84 a) is very similar to *genesæ*, it is of a darker ashy grey ground-colour, the basal area dull brownish grey, the discal spot entirely absent, the postmedian line outside only accompanied by an indistinct shadow, the distinct coherent subterminal line farther removed from the margin. According to a bred ♀ from Loja (Ecuador).

deusta. **E. deusta** H.-S. (84 b) belongs to the same group as the preceding species, the ground-colour is a soft ashy grey with a slight lilac tint, the basal area strewn with red brown, outside defined by a distinct, notched, blackish-brown line, with a thick round discal spot, the blackish-brown notched postmedian line outside accompanied by a fine red-brown shadow; subterminal line beginning with a red-brown costal-marginal spot and receding between 4 and 6 in the shape of 2 thicker spots. Hindwing in the anal-marginal portion only slightly darkened by brownish, with a distinct fine postmedian line as far as beyond the cell, without or with a subterminal line which recedes between 4 and 6 in a large bow and comes very close to the margin between 4 and 3. A most variable, common species from Costa Rica to Brazil.

certina. **E. certina** Drc. (84 b) is very similar to *deusta*, much smaller, darker violettish-grey, the basal area more extensive, so that it extends near to the discal spot, the postmedian line single, extending from 6 almost straight to the inner margin. On the hindwing characterised by the straight median line beginning from the centre of the costal margin and narrowing down into the anal angle; the subterminal line extends only to 3. From the Chiriqui (Panama).

contubernalis. **E. contubernalis** sp. n. (84 b) is very similar to *deusta* and may be a Colombian form of it. Ground-colour violettish grey, basal area dark brown, intensely mixed with black, the proximal half of the median area light silvery grey, between the discal spot and basal area almost white, behind the discal spot between 3 and 6 with a large dark grey spot, the postmedian line outside bordered with light rusty yellowish and strewn with red-brown; subterminal line composed of small black sagittary spots, almost parallel to the margin, between 4 and 6 transformed into a large blackish-grey spot which, however, hardly recedes; before the fringes being very brightly speckled black and light ochreous, there is on the light yellow ground a rusty brown marginal line. Hindwing in the basal and anal-marginal area light brown, in the apical portion of the costal margin and at the distal margin violettish-grey, the median line as in *certina*, the subterminal line composed of very thick blackish-grey spots, very irregular, before the fringe with a light yellow marginal line. Prothorax almost whitish. Type: 1 ♂ from Villavicencio (Colombia) in the Coll. BANG-HAAS.

efferata. **E. efferata** sp. n. (84 b) may be another form of *deusta*; the marking is the same as in *certina*. Forewing brownish-grey, densely strewn with dark brown, so that the basal area is but slightly darker; discal spot very small; postdiscal line single, shaped as in *deusta*, at the costal margin behind it a white brightening, the subterminal line rather indistinct, receding a little between 4 and 6 as a large spot, the veins in the subterminal and marginal areas distinctly black. Hindwing lighter violettish-grey, only towards the base darkened brown by the median line which is shaped as in *certina*; subterminal line slightly curved, more regular than in the similar species, inside shaded by a brownish grey, outside narrowly bordered with light, the dark fringes on the ends of the veins hardly lighter, slightly speckled with yellowish, at the tips whitish. Type: 1 ♂ from Rio Grande do Sul in the Coll. WERNICKE, Dresden.

praedicabilis. **E. praedicabilis** sp. n. (84 b). Forewing light bluish ashy grey, basal area rusty yellow, strewn with black and edged by a black dentate line, behind it with some silvery grey scales, discal spot black, angular close behind it, the outermost costal margin narrow light yellow, the postmedian line hardly indicated, only at the costal and inner margins better visible, subterminal line likewise only composed of very feeble, small wedge-shaped spots of a slightly darker brownish-grey colour, of the same shape as in *deusta*; the light yellowish-white fringes between the veins blackened. Hindwing very similar to some *deusta*, basal area light brown, anal margin broadly covered with blackish-brown hairs, the postmedian line in the costal portion very thick, the subterminal line feeble, receding in a flat bow between 4 and 6. Body ashy grey, the abdomen particularly at the base somewhat more brownish. Type: 1 ♂ from Campo Bello, Rio de Janeiro (Brazil) in the Coll. W. HOPP, Charlottenburg.

divulsa. **E. divulsa** sp. n. (84 b). Near to *varma* Schs. Forewing on the whitish ground densely strewn with a violettish pink and chestnut-brown, in the basal area blackish-grey intermixed with white scales like the thorax; discal streak small, between it and the basal area a small white spot; veins fine red-brown, strewn with black and white, postmedian line quite shadow-like, intensified by fine black vein-dots, particularly at the costal margin outside feebly powdered with whitish; subterminal line just as shadow-like, outside somewhat more distinctly bordered with whitish; fringes blackish-grey. Hindwing producing the same impression as

forewing, in the anal-marginal area with light brown hairs, in the basal half of the costal margin densely strewn with black, outside bordered by the thick black median line which extends from the cell more indistinctly brownish-grey to the anal angle; subterminal line and fringes as on forewing. The ♀ is on the whole greyer, more monotonous, the subterminal line on both wings more distinct. Types: 1 ♂, 1 ♀ from Sa. Catharina (Brazil) in the Coll. WERNICKE, Dresden.

E. combusta *sp. n.* (84 c) is similar to the ♀ of *disulsa*, larger, more distinctly red-brown with a slight pink tint, the basal area strewn with black, with some white scales particularly at the inner margin, the border-line black, double, the discal spot thicker, the postmedian line much more notched, outside with white vein-dots; subterminal line shaped as in *genesia*, beginning with long costal spots, pointedly notched, before the fringe a fine dark marginal line. Hindwing somewhat lighter, in the basal and anal-marginal portion brown, the median line only extending to the cell, the subterminal line very deeply and irregularly notched. According to 1 ♀, habitat unknown. Type in the Coll. STAUDINGER in the Berlin Museum.

E. taedia *sp. n.* (84 c) is similar to *combusta*, lighter, more greyish-brown, without the pink tint, the basal area not strewn with black and white, only slightly darker greyish-brown, lighter towards the antemedian line which does not form the border; discal spot very thick, quadrangular, jet-black; the finely notched postmedian line is greyish-brown, also the irregular subterminal line which projects far towards the margin between 3 and 4, as well as 6 and 8. On the hindwing the larger anal-marginal portion is greyish-brown, the distal margin remains behind the subterminal line of a lighter ground-colour like the costal-marginal portion. Median line very short. Type: 1 ♀ from an unknown habitat in the Coll. STAUDINGER in the Berlin Museum.

E. spectans *sp. n.* (84 c) is another member of this confused group, and is also allied to *distincta spectans*. *Btlr.* Forewing greyish-brown, basal area not darker, lines similarly arranged as in the preceding species, but the median area is much narrower, the brownish-grey, feebly dentate lines on the averted sides bordered with whitish, also the thick round black distal dot is in a lighter ring; the subterminal line is inwardly broadly shaded with dark. Hindwing in the apical costal portion very light, behind the short black median line almost whitish, subterminal line pointedly notched. Type: 1 ♀ from Joinville in the Berlin Museum.

E. cinerulenta *Dogn.* (84 c) is similar to *spectans*; the median area is broader, the transverse lines are more distinctly bordered with white, the posterior line with vein-dots, the discal spot smaller, not in a light ring, behind the subterminal line the marginal area is lighter. Hindwing more unicoloured, subterminal line differently shaped, not notched, only on 3 approaching the margin. From Chanchamayo (Peru).

E. chera *Schs.* (84 c). Forewing greyish-brown, in the basal area somewhat darker, two black border-lines being distinct in the ♂ at least at the costal margin, a thick black discal dot behind it, and a finely notched postmedian line behind which there is an indistinct double line; subterminal line shaped as in *combusta*, outside feebly lighter. Hindwing copper-brown, in the costal portion narrowly coloured as on forewing, median line short, subterminal line near the margin, distally bordered with a lighter colour. In the ♀ the lines are more indistinct, the basal portion is darker, on the hindwing the apical costal half lighter whitish-grey. Brazil, Colombia.

E. varma *Schs.* (= *yoha Schs.*) (85 g). Anterior body violettish-grey and brown, intermixed with black hairs, abdomen brown. Forewing violettish-grey, strewn with brown, in the basal third blackish-brown, outside bordered by the black antemedian line behind which the ground-colour is somewhat lighter grey; before the cell-end a white spot, outside with the black discal streak; the shadow-like feeble postmedian line is intensified by white vein-dots or streaks, the very feeble indistinct subterminal line blackish. Hindwing dull lilac-brown, at the costal margin as on the forewing with a thick black median shadow. Costa Rica, Guiana.

E. intuta *Dogn.* (84 d). Forewing pinkish-grey, feebly strewn with ochreous, particularly on the veins; basal portion black with yellowish hairs, outside bordered by a black line which projects deeply submedianly; the postmedian line is extremely feeble, composed of fine vein-dots; the feeble subterminal line is composed of small greyish-black wedges; before the cell-end there is a small whitish spot. Hindwing as forewing, in the basal half of the costal margin black with yellowish hair, defined by a median line which is shaped as in *certima*; subterminal line feeble, deeply incurved between 4 and 6. Guiana; Colombia.

E. directilinea *Schs.* (85 g). Body dull brown, the darker thorax intermixed with grey. Wings brownish-grey, forewing in the basal third brown, bordered by a velvety brown straight line, postmedian line absent, of the subterminal line only traces are present. Hindwing as forewing, the border-line of the dark basal portion is irregular and is expanded at the costal margin into a blackish-brown spot. Expanse of wings: 37 mm. French Guiana.

E. rectidivisa *Dogn.* (85 g) is very similar to *directilinea*, but much larger, the median area grey, towards the dark grey base whitish, the marginal area behind the postmedian line reddish-brown; the line bordering on the basal area is just as straight as in *directilinea*, the postmedian line is brownish ochreous, in the lower half only composed of vein-dots, the blackish subterminal line outside bordered with light. Hindwing brownish, the median line outside bordered with light. Expanse of wings: 47 mm. Yahuarmayo, Peru.

- maha*. **E. maha** Schs. (84 d). Body brown; forewing in the basal third brown, distally strewn with whitish and traversed and defined by two fine black parallel lines; the proximal half of the median area is white, distally turning sandy brown, at the cell-end a black dot; the darker shaded postmedian line exhibits white vein-dots, like the subterminal line. Hindwing in the basal costal portion darkened, behind the postmedian broad darkening lighter whitish; subterminal line feeble, irregularly shaded. Brazil.
- temblora*. **E. temblora** Schs. (84 d) is smaller, darker, the white colour in the median area narrower; on the hindwing the border-line of the dark basal portion is removed more into the centre, and not oblique, but vertical to the anal angle, the subterminal line is much more indistinct, in the dark ground of the hindwing more extinct. Size stated in the original description 29 mm. but from the Berlin Museum there is a specimen before me identified by SCHAUß, which is as large as *maha* and served us as our figure.
- renesca*. **E. renesca** Schs. is still much smaller. Expanse of wings: 26 mm. Head and thorax blackish, at the shoulders mixed with whitish, abdomen light brown. Forewing dark grey, basally slightly strewn with black, with a fine blackish antemedian line which is distally bordered with white; discal spot absent; the fine postmedian line is dark with white vein-dots; the dark subterminal shadow is almost straight, outside above 5 shaded with grey. Hindwing light brown, costal portion and apex grey with a dark median shadow which is distally bordered with white; subterminal line in the grey part white; below 4 dark. French Guiana.
- mendosa*. **E. mendosa** sp. n. (84 d) is very similar to *maha*, larger, more slender, forewing longer, more pointed with a more oblique distal margin; basal third dark brown, before the black antemedian line with 2 broad white, twice angular transverse lines; the proximal half of the median area is white with a thick black discal dot, outside turning blackish-brown, defined by the black postmedian line which is angular on 4 and 9 and distally bordered with white and followed by a second black parallel line; before the subterminal line, which is shaded with greyish-black, at the costal margin a dark spot; hindwing greyish-brown, in the costal portion white with a brownish median line therein; subterminal line very irregular, on 6 projecting to the margin. Described from 1 ♂ without the habitat being mentioned; type in the Berlin Museum.
- prodiga*. **E. prodiga** sp. n. (84 d) is another species from the *maha*-group; larger, with broader and rounder wings. Body grey intermixed with black hairs, above at the base of the abdomen with a brown tuft. Forewing in the basal third blackish-brown, distally strewn with white, towards the fine deep black antemedian line all black, in the centre traversed by another broad white line; median area white, towards the black postmedian line, the lower part of which is almost vertical, strewn with blackish-brown; discal dot black. Distal third brown, shaded with black, the subterminal line, the upper portion of which is spotted, outside, in the upper half also inside light brown; fringes slightly, on the hindwing more distinctly speckled, the latter light chocolate brown, in the apical costal portion broad white, bordered by a short deep black line; subterminal line more regular than in *maha*. According to 1 ♂ from Minas Geraes (Brazil); type in the Berlin Museum.
- obtusa*. **E. obtusa** H.-S. (= *morosa* Btlr.) (84 d) is likewise allied to the *maha*-group. Body and wings brownish sand-coloured, with a faint pinkish tint; basal third of forewing deep blackish-brown, outside bordered by a black double line, behind it the thick black discal dot; the fine dark postmedian line likewise double, subterminal line composed of small greyish-black wedges. Hindwing at the apex whitish, before the median line bordering on the apex darker brown; subterminal line feeble, shaded with grey. Brazil. In the Berlin Museum 1 ♂ with the manuscript name: *albomacula* Maassen.
- exotérica*. **E. exotérica** sp. n. (84 d) is somewhat like *obtusa*, smaller, darker, more red-brown, the dark basal area outside more roundly defined, the discal spot coincides with the antemedian line, the median area is much narrower, the veins in it partly black. On the hindwing the light apex is much smaller, the border-line much obliquely, extending towards the centre of the anal margin, in *obtusa* to the anal angle. Type: 1 ♂ in the Berlin Museum, habitat not mentioned, with the manuscript name: *exotérica* Maassen.
- discorica*. **E. discorica** Dyar is similar to *obtusa*, but the median area is narrower, whiter, the transverse lines stronger and distinctly double; basal area suffused with black, in the white median area with the large oval black discal spot. Expanse of wings: 25 mm. Panama (Taboga Island).
- lepta*. **E. lepta** Schs. (85 g). Body and wings brown, forewing basad particularly in and below the cell clouded with black, enclosing a fine white irregular line, at the cell-end a small light spot; behind it follows a yellowish-red band distally bordered by the double postmedian line with white vein-dots; subterminal line very feebly darker. Hindwing with a blackish-brown median stripe at the costal margin, behind it at the apex lighter with the dark subterminal line. Costa Rica.
- parepa*. **E. parepa** Schs. (84 d) is allied to the preceding *obtusa*-group. Forewing dark brown, at the base darkened by blackish, in the median area lighter yellowish-reddish white, towards the inner margin strewn with red-brown enclosing the oval black discal spot; both the transverse lines are double, filled with whitish, subterminal line composed of small blackish spots, receding as usual between 4 and 6. Hindwing very dark brown, at the costal margin behind the median line lighter whitish, subterminal line rather indistinct. Brazil (Castro: São Paulo).

E. chamicuros Schs. (84 e) is somewhat larger than *parepa*, the light median area divided into two *chamicuros*, large spots at the costal and inner margins; the transverse lines disappear more or less; subterminal line as in *parepa*, hindwing the same. Peruvian district of the Amazons.

E. resarta sp. n. (84 e) is still smaller than *parepa*, the whitish median area reduced to a roundish *resarta*, inner-marginal spot; the anterior transverse line is distinctly double, filled with grey, the posterior line single with white vein-dots; subterminal line inside shaded with grey, receding far between 4 and 6; before the fringe there is a fine black limbal line dotted white on the ends of the veins. Hindwing in the costal-marginal portion hardly lighter with the beginning of a subterminal line before the apex. According to 1 ♂ from Thomar, type in the Berlin Museum in Coll. STAUDINGER.

E. petrovna Schs. (85 g). Body light brown, thorax somewhat darker. Forewing light brown, basal *petrovna*, area dark brown, outside bordered by the double black antemedian line, at the cell-end a small brown spot; the dark brown posterior transverse line is likewise double; the subterminal line is reduced to some blackish apical dots. Hindwing blackish-brown, in the costal portion broad light brown with a dark median line and subterminal shadow, the latter distally bordered with greyish-brown. Expanse of wings: 31 mm. Brazil (Petropolis).

E. larunda Drc. (84 c) is the chief representative of a small group of similar species with a more *larunda*, or less white median area. Basal area deep red-brown, strewn with black, narrowly lighter towards the double antemedian line which borders on it; in the cell with a small discal spot, the narrow median area variably strewn with grey, the postmedian line single with short black vein-streaks which are distally dotted white; in the marginal area, which is densely strewn with greyish-brown, there is before the notched subterminal line another greyish-brown shadow-like band. Hindwing light brown with a white apex, inwards defined by a thick brownish-black median line. Thorax blackish-brown, abdomen light brown. Costa Rica to Peru and Brazil. On plate XXII of the Biologia the signatures of *larunda* and *laronica* have been exchanged, which gave rise to many errors.

E. consolabilis Dyar (84 e) is similar, the basal area much lighter, light ochreous, strewn with *consolabilis*, blackish-brown, the discal and marginal areas uniformly light grey, the former only somewhat lighter, the markings as in *larunda*, but finer. Hindwing much lighter, apex and a great part of the marginal area whitish-grey. The much larger ♀ is more uniform, in the basal area brownish, also in the postmedian area and at the margin. Mexico; Costa Rica. — f. **colombiensis** (84 e) is somewhat browner, particularly the hindwing more *colombiensis*, extensively red-brown, the antemedian line more excurved, more distinctly dentate, a white discal dot is distinct, the median area narrower and greyer, the marginal area browner. Villavicencio (Colombia); type in the Coll. BANG-HAAS.

E. larundina Schs. (84 f) differs from the preceding species in its browner wings; the whole median *larundina*, area is of the same colour as the marginal area, reddish greyish-brown, at the cell-end a small white spot, the posterior transverse line with white vein-dots, the brown subterminal shadow dentate. Hindwing light brown, in the basal half of the costal margin dark brown, at the apex and distal margin somewhat lighter grey. Costa Rica to Colombia (Villavicencio).

E. gundlea Schs. (85 g). Described from 1 ♀ from Rurrenabaque (Bolivia). Anterior body claret- *gundlea*, coloured yellowish-brown, mixed with grey and white, abdomen wood-coloured. Forewing greyish sand-coloured, in the basal area, which extends at the costal margin to the centre of the wing, at the inner-margin to the first third, claret-coloured brown, distally bordered by the double antemedian line; postmedian line likewise double, subterminal line dark grey, partly bordered with white. Hindwing brown, at the apex sand-coloured grey. Expanse of wings: 32 mm.

E. unda Dogn. (85 h) is in the basal area of the forewing yellowish-brown, the antemedian line *unda*, bordering on it form two bows and is sinuate before the brown discal streak; the rest of the wing is reddish-grey with a fine double postmedian line, angular below the costal margin and with small subterminal brown wedges. Hindwing light yellowish-brown, at the costal margin apically grey with a median border-line and a subterminal line, both of which are only distinct at the costal margin, then hazy and indistinct. Expanse of wings: 24 to 26 mm. French Guiana.

E. albidifascia Wkr. (84 f) has more stretched wings, the basal area is red-brown, the black notched *albidifascia*, antemedian line is double, the median area powdered with grey, without a distinct discal dot; the distal area is reddish-brown or reddish-grey, the postmedian line composed of vein-dots or streaks, often with an indistinct brown shadow behind it, the grey subterminal line being distally bordered with light is sharply notched. Hindwing light brown, in the basal half of the costal margin red-brown, at the apex whitish-grey, which colour extends behind the irregular subterminal line along the distal margin. Costa Rica, Panama.

E. rivulosa Möschl. (84 f) is intermediary between *consolabilis colombiensis* and *albidifascia*, darker *rivulosa*, than the former, the wings not so stretched as in the latter. Basal area of forewing more strewn with blackish-brown on the dark red-brown ground, with a distinct white discal spot behind the antemedian line, the median area proximad narrowly reddish-brown, then violettish-grey or lead-coloured; postmedian line double, the interior portion composed of black vein-streaks, the exterior portion of a red-brown shadow-like line. Marginal area lighter brownish than in *albidifascia*, subterminal line distally not bordered with white. Hindwing darker brown. Guiana to Colombia.

- poasia*. **E. poasia** Schs. (84 f) is a much larger species, the base of the forewing is light brown, costally darker, the rest of the surface greyish-white strewn with red-brown, discal dot absent; the almost straight interior postmedian portion dotted on the veins, behind it a red-brown shadow-like stripe, at the costal margin more remote than at the inner margin, discally incurved. Described from Costa Rica.
- egra*. **E. egra** Schs. (84 f). Here the basal area is light yellow, the double dark brown antemedian line filled with red-brown, the median and marginal area light bluish-grey, subterminal area light yellow; discal streak small, black; subterminal line strongly curved. Hindwing very light reddish-brown, at the apex extensively white, in the basal half of the costal margin blackish-brown. The ♀ is much larger and darker, the basal and subterminal area dark ochreous, the median and marginal areas like the hindwing almost blackish-brown. Costa Rica to the Amazons (São Paulo de Olivença), here darker, greyer.
- gera*. **E. gera** Schs. is very similar, basal area of forewing yellowish-reddish, strewn with brown, the double blackish antemedian line filled with light brown, the whole distal area mouse-coloured; postmedian shadow light brown, inside bordered with a darker grey, and crossed by a darker line; subterminal line whitish-grey. Hindwing light red-brown, basally at the costal margin brown, defined by the dark brown postmedian line against the light grey apex, subterminal line darker grey. Costa Rica; Guiana; Venezuela.
- limba*. **E. limba** Drc. is browner on the forewing, in the basal area lighter, the antemedian line is double, the median area darker brown, outside behind the single postmedian line bordered by a somewhat lighter colour. Subterminal line irregularly dentate, shadowy grey, distally not bordered by a lighter colour. Hindwing monotonously slate-coloured brown, at the apex hardly lighter. The ♀ is much larger, more monotonous, more reddish-brown, the antemedian line only single. Costa Rica.
- canities*. **E. canities** Schs. (85 h). Body olive-brown. Forewing from the base to the dark discal streak whitish, strewn with yellow and olive-brown as far as the fine double, almost straight antemedian line; distal half of the wing olive brown, behind the discal streak with an almost straight darker line and behind it an irregular dark shadow; subterminal shadow very broad, at the apex distally curved. Hindwing olive brown, in the costal-marginal half whitish, strewn with olive-brown, with a dark median shadow and broad darker subterminal shadow. Costa Rica.
- lanea*. **E. lanea** Schs. (85 h). Body dull brown, thorax grey; forewing at the base white strewn with black, the median area of a purer white, the distal half thickly strewn with brown; antemedian line black, almost straight from the costal margin to 2, then inwardly interrupted and obliquely to the centre of the inner margin, the dark brown fine postmedian line forms 3 small bows below the costal margin, between 3 and 5, and below 2; subterminal shadow brown, irregular. Hindwing dull brown, at the costal margin broad grey, at the distal margin narrow grey with dark median and subterminal lines. Expanse of wings: 33 mm. Costa Rica.
- mediana*. **E. mediana** Schs. (85 h) is somewhat smaller, head and thorax grey, abdomen brown. Forewing brown, at the base a small dark spot; the whitish median area on each side bordered by a grey shadow; the dark subterminal line is undulate. Hindwing brown, at the costal margin broad whitish with traces of dark median and subterminal shadows. Expanse of wings: 31 mm. Rio de Janeiro.
- amida*. **E. amida** Drc. (84 g). Forewing in the basal and marginal areas light grey, strewn with brownish, at the margin with fine dark veins; the median area is white, very scantily — particularly towards the costal margin — strewn with grey, with a very feeble dark discal dot; antemedian and postmedian lines finely dentate black, the former line deeply incurved submedianly, the posterior line inwards prolonged to small fine black dents, with a feeble brownish-grey shadowy line behind it; subterminal line composed of small feeble dark wedges. Hindwing brownish, at the costal margin only slightly whitish, behind the fine dark subterminal line the margin is narrowly lighter. Ecuador.
- pseudamida*. **E. pseudamida** Dogn. is very similar to *amida*, the antemedian line is double, without the deep submedian inward tooth; postmedian line likewise double, but only the anterior portion is distinct and black, in the median area with a large black discal dot; subterminal line more deeply dentate, parallel to the margin; the white fringe blackened between the veins. Hindwing in the costal-marginal portion much broader white. French Guiana, also from Costa Rica and Colombia.
- argyphaea*. **E. argyphaea** Berg (= *varona* Schs.) (85 h). Anterior body and base of abdomen light brownish-grey, abdomen rusty brown. Forewing in the basal half silvery white, scantily strewn with grey, in the distal half brownish-grey, in the postmedian area darkened; antemedian line hardly visible, the postmedian line forms a large bow between 4 and 7, the subterminal line is strongly dentate; fringes on the ends of the veins interrupted by white; hindwing rusty brown, in the costal-marginal half white with a median line and a subterminal line. Expanse of wings: 27 to 33 mm. Brazil (Rio de Janeiro).
- albigrisea*. **E. albigrisea** Schs. (85 h) is allied with *argyphaea*; thorax dark greyish-brown, abdomen reddish-brown, dorsally at the base blackish-grey. Forewing white, on the veins strewn with grey and brown, at the inner margin narrowly dark greyish-brown as far as the centre, then expanded along the distal margin as far as 7, a dark undulating postmedian line separates both the colours, above 7 passing over into an irregular white apical patch. Hindwing white, at the anal margin broad light brown. Expanse of wings: 27 mm. Costa

Rica; British Guiana. — In v. **fusca** Dogn. all the white areas are replaced by rusty reddish with white irroration, *fusca*, the postmedian line being distally bordered with white; faint traces of a double antemedian line. Hindwing the same. According to 1 ♂, expanse: 26 mm, from French Guiana.

E. mus Dogn. described according to a single ♀ from Pacho (Colombia) is monotonously mouse-*mus*, coloured with fine darker veins; only in a certain exposure to light there appear faint traces of transverse lines and of a subterminal line, as well as a discal streak. Expanse of wings: 40 mm.

E. nebula Schs. (85 h). Anterior body dark brown, abdomen more brownish ochreous. Forewing *nebula*, whitish-grey, scantily strewn with brown, behind the postmedian line with dark brown veins; the olive-brown antemedian line is double, irregularly curved, the postmedian line likewise double, the exterior portion below 6 expanded into a shadow; the subterminal line is confined to small dull grey spots between 2 and 5, and 6 and 8. Hindwing whitish, veins in the marginal area brown, at the anal margin broadly covered with ochreous hair, with a fine dark median band. The ♀ is much larger, dark olive brown, the 3 last abdominal rings ochreous. The wings are much darker, basad olive brown, in the exterior half smoky brown, the median area very narrow, dingy white with a dark spot at the cell-end. Expanse of wings: ♂ 33, ♀ 47 mm. Costa Rica.

E. nubiplena Dogn. (= *nebulosa* Dogn.) is very closely allied to the following *fibra* from which it *nubiplena*, differs in entirely grey forewings on which only the costal margin as far as the cell, and the subterminal line remain whitish, the latter beginning with a white apical streak; marginal area slightly lighter. Hindwing white, at the anal margin with yellowish-red hair, in the costal-marginal portion with the beginnings of several lines. Expanse of wings: 31 mm. Colombia.

E. directa Schs. (85 h) is likewise closely allied with *fibra* which, however, exhibits a narrower white *directa*, median area. In *directa* the grey basal area is defined by a dark antemedian line which is angular below the costal margin and inwardly dentate above the submedian, and uniting at the inner margin with an oblique line from the cell, both the lines being double: the dark grey postmedian line is likewise double, almost straight; the subterminal shadow is much fainter and narrower, distally bordered with white; veins fine dark grey. Hindwing white, at the anal margin broad ochreous, the dark median line curved before the anal margin, a grey subterminal shadow only visible at the apex. Expanse of wings: 36 mm. Costa Rica.

E. fibra Schs. (= *lacinia* Drc.) (84 g) is a very common, widely distributed species. Forewing of *fibra*, ♂ in the basal half white, with fine blackish-grey veins, basally somewhat blackened, both the transverse lines double, the anterior line curved, the posterior line after an angle below the costal margin almost straight to the inner margin: subterminal shadow dentate, outside feebly bordered with whitish. Hindwing white, basally and at the anal margin broadly covered with ochreous hair, with a median line and a subterminal line, fringe grey. Abdomen with lateral ochreous hair. The very much larger ♀ is much darker smoky grey, the median area narrow, abdomen extensively covered with ochreous hair. Mexico to Brazil. — **cayennensis** f. n. (84 g) *cayennensis*, is more olive brownish, also the median area, the two transverse lines very close together, filled with white, the veins in the median area below the cell thicker black, the subterminal line somewhat differently shaped, forming a large bow below the costal margin, then on 4 a pointed tooth as far as the margin. From Cayenne. Arouary (Guiana).

E. ciniala sp. n. (81 f) is allied to the preceding species. Forewing thinly scaled, white, basally *ciniala*, and in the inner-marginal half and in the distal-marginal area, excepting the apex, on the brownish-grey ground strewn with greyish-black; veins blackish-brown, on the transverse lines interrupted by white; the latter double, the anterior line complete, broadly filled with white, before it below the cell densely clad with snow-white hair, the posterior line indicated by double vein-streaks; subterminal line only distinct in the upper half, composed of white lunae being inwardly dusted with a somewhat darker grey. Hindwing white, in the inner-marginal portion with rusty yellow hair, before the greyish-brown fringe with a blackish limbal line, at the costal margin with feeble beginnings of lines. Thorax blackish-brown, abdomen browner, under surface covered with lustrous rusty brown hair. According to 1 ♂ from Humbo near Muzo (Colombia); type in the Coll. W. HOPP, Charlottenburg.

E. abolla sp. n. (81 f). The whitish ground is so densely powdered and strewn with a brownish greyish-*abolla*, black that but faint traces remain of the transverse lines which are bordered with whitish; the most distinct are the small lunular spots of the subterminal line and a conspicuous roundish spot behind the postmedian line between 5 and 6; small discal spots feebly darker; veins particularly in the disc finely dark brown. Hindwing at the costal margin somewhat darker, containing the beginnings of 2 lighter lines. According to 1 ♀ from Sa. Catharina in the Coll. WERNICKE, Dresden.

E. ochropyga Fldr., the type of which is no more to be found, I only know from the figure in the *ochropyga*, Biologia, according to which it can only be a ♀ of *fibra*, though the subterminal line is quite straight, parallel to the margin; any other essential differences are not to be seen from the evidently not very true figure. Amazons. Thus the name *ochropyga* would have to replace *fibra*.

E. salebrosa sp. n. (84 g) is not quite dissimilar to a *fibra*-♀. Forewing brownish-grey, strewn with *salebrosa*, a darker colour, at the extreme base and in the median area lighter brownish; transverse lines single, only the posterior line shows below the costal margin traces of a doubling, and it projects far distally on 4 and 8; the

dark subterminal line is notched, outside narrowly bordered with white. Hindwing brownish, at the costal margin narrowly strewn with white, with a notched subterminal line and a short postmedian line. Thorax ashy grey, abdomen absent. According to 1 ♀ from Rio de Janeiro, type in the Berlin Museum in the Coll. STAUDINGER.

viridiflava. **E. viridiflava** Schs. (84 g) is very light greenish sulphur-coloured, with shadow-like brownish antemedian and postmedian transverse bands, and a brownish discal shadow between them; the subterminal line is composed of a curved row of small greyish-brown spots, the margin behind it being likewise darkened by greyish-brown, the broadest in the centre. Hindwing in the larger anal-marginal portion, in the yellowish apical and costal-marginal portion with shadow-like lines. French Guiana.

chlorobasis. **E. chlorobasis** sp. n. (84 h) is coloured as *viridiflava* in the basal half of the forewing, as well as on the thorax and the dorsum of the 3 first rings, the rest of the body as well as the distal portion of the forewing and the hindwing dark greyish-brown; the anterior transverse line is punctiform, the posterior line with vein-dots behind it and a whitish filling between them, in the distal half of the median area strewn with black, with a fine black cell-end streak; subterminal line inwardly shaded by a darker colour, outside bordered with light. Hindwing at the costal margin and behind the subterminal line somewhat lighter, at the costal margin with shadow-like beginnings of lines. According to 1 ♂ from Villavicencio (Colombia) in the Berlin Museum.

fulvago. **E. fulvago** sp. n. (84 h) almost resembles a *Tolyte* from the *hella*-group; light ochreous white with darker ochreous, almost straight transverse bands, 3 each before and behind the centre, at the cross-vein a short ochreous transverse streak, the marginal area behind the subterminal line somewhat greyer; the veins around the transverse bands and particularly at the distal margin finely darkened. Hindwing lighter, in the costal-marginal portion with the beginnings of 3 shadow-like darker transverse bands. According to 1 ♀ from Macas, Ecuador, in the Coll. BANG-HAAS.

lyso. **E. lyso** Drc. (84 h). Wings light reddish-yellow, forewing with dark brown transverse lines, the antemedian line only visible in the costal half, double, the postmedian line very thick, at the costal margin double, at the cell-end with a black discal streak; the undulating subterminal line reddish-brown, behind it the marginal area is darkened by a greyish brown; fringes undulating. Hindwing as forewing. From the Chiriqui (Panama); type in the Coll. STAUDINGER in the Berlin Museum.

banghaasi. **E. banghaasi** sp. n. (84 h) shows a certain resemblance to *lyso*, but it is much more closely allied to the *ogenes-deusta* group. Forewing pale yellowish loam-coloured, scantily strewn with blackish-brown, at the costal margin and the transverse lines more whitish; basally more densely strewn with brown, chiefly in the cell before and behind the antemedian line which is notched, only in the upper half distinct, with hazy double shadows before it, the postmedian line the same, particularly below the costal margin filled with white; at the cell-end with a thick blackish-brown spot; the subterminal line is composed of small feeble brown spots, parallel to the distal margin, interrupted between 4 and 6, receding far at the costal margin with an intense dark brown triangular spot. Hindwing in the larger anal-marginal portion excepting the distal margin somewhat more reddish brown like the abdomen, at the costal margin with the beginnings of brown, outside white-edged lines, the subterminal line being shaped as on the forewing; fringes on both wings spotted black between the veins. According to 1 ♀ from Macas (Eastern Ecuador), type in the Coll. BANG-HAAS.

inflata. **E. inflata** Schs. (85 i) is yellowish-reddish on the body and wings, the abdominal tufts are violettish-brown, the very long anal hair reddish-brown; the two light transverse lines are united above the anal margin and enclose here a reddish-brown spot, the median area above it is powdered with grey; at the cross-vein there is a very thick dark red-brown oval spot; small subterminal spots very feeble and only better visible by the light exterior border, terminating apicad with 2 small red-brown spots; at the distal margin between the veins small white lunular spots outside bordered with brown. Hindwing somewhat darker. Costa Rica to Brazil.

amazonica. **E. amazonica** Btlr. (84 h) is somewhat smaller, more brownish, the median area above the inner margin darker brown, the posterior transverse line distinct, double, the subterminal line more distinct, especially in the lower half very much notched; the discal streak is feebler, the white marginal lunae particularly analwards very strong. Hindwing lighter than forewing; fringes analwards on both wings mixed with white. Panama to the Amazons.

torrida. **E. torrida** Schs. (84 h) is a small, more common species. Forewing dark brown, transverse lines very indistinct, only better visible by the lighter grey spots on the averted sides; from the discal streak a blackish shadow extends to the apex, below this shadow a subterminal brightening expands in the upper two thirds; the subterminal line itself is composed of a series of small grey spots almost parallel to the margin; before the fringe a light limbal line. Hindwing almost monotonously brown, at the margin behind the shadow-like, indistinct subterminal line somewhat lighter. Costa Rica to Brazil (Joinville).

pompilus. **E. pompilus** Dogn. (84 i) is very similar to *torrida*; forewing dark chestnut-brown, basal and in the large crescentiform subterminal spot light reddish-yellow; the two transverse lines more distinct than in *torrida*, feebly double, without small light spots; subterminal line dark, undulately dentate. Hindwing monotonously light red-brown. Loja (Ecuador).

moisa. **E. moisa** Dogn. (85 i) is on the forewing in the basal half blackish-brown, outside light brown, subapically turning whitish; the basal dark colour extends along the costal margin to shortly before the apex.

the two transverse lines are indicated by light vein-dots, and there is a subterminal row of small dark internerval dots. Hindwing brownish ochreous, at the costal margin somewhat darker. South-Eastern Peru.

E. albidula Dogn. In this species being closely allied with *torrida* and *pompilus*, the large subterminal crescentiform spot is of a pure white, not yellowish or brownish; the two transverse lines are marked by white vein-dots; the white spot passes towards the inner margin over into the chestnut ground-colour in which there are small light grey subterminal internerval spots. Hindwing lustrous red-brown. Expanse of wings: 29 to 30 mm. French Guiana.

E. amisena Drc. (85 i). Forewing dull brown with 3 undulating darker brown transverse lines and an oblong reddish-brown spot near the apex. Hindwing brown with 3 short white inner-marginal streaks; body yellowish-brown. The ♀ is much larger and darker, the forewing intensely strewn with grey, hindwing likewise blacker. Ecuador (Sarayaçu).

E. castalia Drc. (84 i) is brown, both the transverse lines composed of black and white vein-dots, both below the costal margin distally angular, subterminally with a large whitish crescentiform spot which gradually passes over inwards and below into the brown ground-colour; the subterminal line consists of small blackish-brown internerval spots being distally bordered with light. Hindwing and abdomen somewhat lighter. Panama (Chiriqui).

E. flumentana Dogn. is also very similar to the preceding species: forewing chestnut-brown, the two transverse lines shadow-like darker brown, faded, the posterior line with whitish vein-dots; subterminally there is a white band being broad at the costal margin, getting very narrow from 5 to the inner margin, outside of it small black, outside white internerval spots; at the cell-end there is a small black spot. Hindwing lighter brown. Expanse of wings: 32 to 33 mm. Colombia, Cañon del Tolima.

E. erebina Btlr. is unknown to me, but it seems to me to belong also to this group; forewing very dark brown, towards the inner margin somewhat lighter, with a crescentiform very light apical spot, crossed by a feebly undulating, centrally angular blackish subterminal line; the two transverse lines are marked by white vein-dots, the anterior line is indistinct. Hindwing lighter brown and somewhat glossy. Costal margin at the apex blackish, enclosing a whitish spot. Expanse of wings: 1 inch 1 line. Cupari, Rio Negro (January 19th 1874).

E. obsessa Dogn. is above greyish-brown, the base, costal margin, and veins blackened, between the transverse lines being composed of white vein-dots there is a black discal spot, with a dentate dark subterminal line which recedes as usual between 4 and 6; hindwing lighter and greyer in the costal-marginal portion, the rest of the wing red-brown with a subterminal line extending but little beyond the centre. Expanse of wings: 28 mm. French Guiana.

E. lacrimosa Schs. (84 i). Forewing brown, both the blackish transverse stripes double, filled with grey, behind the distal line the marginal area is lighter, subterminally almost white, enclosing the small internerval spots of the subterminal line. Hindwing lighter brown, in the costal-marginal portion blackened with the beginnings of lighter lines, the subterminal line extending almost to the anal angle. Brazil, a more common species.

E. sobrina Schs. (84 i) is very similarly marked, but without the subterminal and marginal brightenings, the transverse lines are double but not filled with grey, only the posterior line at the costal margin somewhat lighter yellowish-red. Hindwing lighter brown, at the costal margin but little darkened brown, with a feeble double postmedian shadow and a feeble light subterminal line. The ♀ is larger, darker, the transverse lines more faded, the posterior line with lighter vein-dots. Costa Rica.

E. phyllis Schs. (84 i). Body brown, at the thorax blackish; forewing light brown, in the costal portion blackened, the broadest in its centre; the two transverse lines indistinctly double with white vein-dots, with a subterminal row of small blackish internerval spots, apically with one more spot behind them. Hindwing duller brown, in the costal-marginal portion blackened with dark brown, partly grey-edged lines. Costa Rica.

E. capillata Schs. (84 i). Forewing uniformly brown, only in the basal costal-marginal half feebly darker, the two transverse lines consisting of somewhat extinct double rows of small blackish lunular spots, the distal line receding between 4 and 6; the subterminal spots in a single row as in *lacrimosa*, but nearer to the margin. Costa Rica.

E. binuba Dogn. Forewing red-brown, feebly strewn with whitish, the markings of the same colour, but not strewn and thereby distinctly prominent; between the two dentate double transverse lines with one black dot each in both the cell-angles, the single dentate subterminal line shaped as in the preceding species. Hindwing red-brown, in the costal-marginal portion strewn with white, enclosing the beginnings of two darker lines. Expanse of wings: 30 to 32 mm. São Paulo de Olivença: Rio Xingu, Amazons.

E. zurcheri Drc. (84 i) is similar to the preceding ones, but blacker with a slight purple tint, the double transverse lines deep black, basally and subterminally between 4 and 6 as well as before the apex at the costal margin somewhat blackened; hindwing brownish-black, with 3 short lines, the last, subterminal one extending almost to the anal angle. Costa Rica.

E. scripturata Dogn. is very similar to *zurcheri* which, however, is larger and blacker. Body and wings reddish-brown, with brownish-black markings: a basal shadow, a double antemedian line, before which

there are 2 black submedian dots, at the cell-end 2 dots, behind them double postmedian and subterminal lines composed of internerval lunae. On the hindwing at the costa the beginnings of 3 lines. Expanse of wings: 25 mm. Lino (Panama).

deceana. **E. deceana** Drc. (84 i, k). Forewing blackish-brown, basad and in the marginal area somewhat lighter yellowish, before the antemedian line especially at the costal margin intermixed with whitish-grey scales; the two transverse lines are double, black, undulating, between them a blackish discal spot; subterminal line feeble, undulatingly dentate. Hindwing monotonously blackish-brown. The ♀ is slightly larger, much more monotonous, the lines quite indistinct, before and behind the subterminal line at the apex greyish-white irroration. Mexico.

orgyia. **E. orgyia** sp. n. (84 k) almost recalls an *Orgyia*; it is much smaller than *deceana* and much more monotonous and deeper brownish-black, only near the interior angle of the forewing somewhat lighter reddish-brown, and apically at the costal margin behind the hardly noticeable subterminal line with some greyish-white scales. Hindwing apically at the costal margin with a small grey spot. According to 1 ♂ from Sa. Catharina (Brazil); type in the Coll. WERNICKE, Dresden.

lola. **E. lola** Schs. (= *dormia* Schs.) (85 i). Body reddish-brown, collar and patagia darker. Forewing light reddish-brown, below the cell basad with a blackish spot; anterior transverse line double, partly filled with whitish, posterior line composed of black, outside white vein-streaks, between both a black cell-end spot; a subterminal row of large black spots. Hindwing light brown with 3 dark grey lines at the costal margin. Expanse of wings: 25 mm. Aroa (Venezuela).

incivilis. **E. incivilis** Wkr. Forewing reddish-brown, short and broad, with white marginal dots, along the costal margin blackened with 3 brown transverse lines; antemedian and postmedian lines with white vein-dots, subterminal line composed of spots. Hindwing reddish-brown, at the costal margin marked like the forewing, with a subterminal line of spots behind which the distal margin is lighter. Expanse of wings: 30 mm. Rio de Janeiro.

similavis. **E. similavis** Kaye is brown with black irroration, forewing with a brown basal hair-tuft and a broad black costal margin as far as behind the median band which is distally sharply defined, proximally faded, containing a small black discal spot: the postmedian line is composed of white vein-dots, the subterminal line of black dots; fringes speckled. Hindwing brown, at the costal margin black with a light median area with 1 or 2 black dots, behind the subterminal line with black dots. Expanse of wings: 30 mm. Trinidad.

celebris. **E. celebris** Schs. (84 k). Forewing brown, in the costal half strewn with greenish greyish-black, with fine dark veins and shadow-like indistinct transverse lines beginning double at the costal margin, filled with whitish; subterminal line as in all the preceding species; fringes on the ends of the veins crossed by light. Hindwing like the forewing, the subterminal line broader, behind it the margin is somewhat lighter. The ♀ is strewn with a redder tint, with still more indistinct markings, hindwing greyish-brown with yellowish-reddish marginal spots. Costa Rica.

nystamma. **E. nystamma** Dyar (84 k) is extraordinarily similar to *celebris*, lighter, more uniformly strewn with dark, the two transverse stripes more distinctly double, between them a discal spot; subterminal area somewhat more whitish, containing larger internerval blackish spots; fringes reddish yellowish-brown; also on the hindwing the subterminal line is spot-shaped. Mexico.

nigropunctata. **E. nigropunctata** Schs. is another similar, smaller species. Body and wings light reddish-brown; forewing with a black spot at the cell-end, only the posterior transverse line is marked by double black vein-streaks with a blackish shadow between them from the costal margin to vein 3; apical veins black, subterminal spots as in *nystamma*, but blacker. Hindwing as in *nystamma*. Expanse of wings: 29 mm. Central Brazil.

nysaea. **E. nysaea** Dogn. (85 c) from the same group is larger, the forewing more flesh-coloured white, with basal and subcostal black clouds, submedianly strewn with yellowish-red, and in the distal area strewn with black, with ochreous veins and a black discal dot; basal and antemedian transverse lines double, the posterior line single, dentate, with white vein-dots, at the costal margin outside bordered with white, behind it with a feeble ochreous line; subterminal line dentate, on both sides powdered with white, the veins speckled black and white. Hindwing flesh-coloured white, in the costal-marginal portion with black, at the anal margin with yellowish-red hair, the margin behind the subterminal line white. Expanse of wings: 35 to 36 mm. Rio Songo (Bolivia).

boresa. **E. boresa** Schs. (85 i). Forewing yellowish-red, in the disc and broadly at the costal margin with smoky blackish clouds, the veins in the distal half reddish-brown; transverse lines absent, excepting the undulate smoky blackish subterminal shadow. Hindwing lighter, at the anal margin with brown hair, with a large blackish area at the apex, from which the subterminal shadow extends to the anal margin. Expanse of wings: 22 mm. Aroa (Venezuela).

venalia. **E. venalia** Schs. (84 k) is on the body and wings light yellowish-red, basally darkened, with double blackish undulating transverse lines filled with whitish, and a black discal dot between them; subterminal line composed of small blackish wedges. Hindwing white, at the costal-marginal portion yellowish-red with the beginnings of grey lines, partly bordered with whitish. Aroa, Venezuela.

E. guttivena Wkr. (85 i) is all white, with black dots on the veins arranged as in *venalia*, and a brown *guttivena*, spot at the anal angle of the hindwing. Thereby it resembles an *Artace*. Rio de Janeiro.

E. pygma Schs. (84 k). Forewing scantily scaled blackish-brown with fine darker veins and a black *pygma*, discal spot, in the disc at the costal margin and behind the subterminal line lighter whitish, the broadest apically and at the inner angle; transverse lines shadow-like darker, indistinctly double. Hindwing at the costal margin broad whitish with feeble darker lines therein. Brazil.

E. vandrilla Schs., described from a ♀ from Villarica, Paraguay, has an expanse of but 28 mm. Body *vandrilla*, and forewing sand-coloured brownish, excepting the transverse lines strewn with drab, the latter lines feebly double, the posterior line almost vertical; at the cell-end there is a dark dot; a subterminal row of small brownish spots. Hindwing only at the apex and margin strewn with drab.

E. casimir Schs. (85 i). Body and wings brown with dark brown irroration, at the inner margin as *casimir*, well as on the head and palpi cinnamon-coloured orange; at the cell-end 2 black dots; only a double white subterminal line is distinct, parallel to the margin. Hindwing brown, at the margin and apical fringe a few white hairs. Expanse of wings: 30 mm. French Guiana.

E. castrensis Schs. (84 k). Palpi yellowish; anterior body and forewing bluish ashy grey with double *castrensis*, dentate transverse lines, the anterior line very strong, deep blackish red-brown, the posterior line much feebler and finer, filled with light yellowish-red; discal spot thick, blackish-red; subterminal shadow feeble, grey. Hindwing white, at the costal margin in the basal half brown, distally grey with grey fringes. Castro; Sul de Minas. (Brazil).

E. spreta sp. n. (84 k). Anterior body and forewing whitish violettish-grey, strewn with red-brown, *spretu*, the most densely at the base and in the median area in the costal half, the double transverse lines filled with greyish-white, between them with a grey discal spot; small subterminal, feeble, red-brown internerval spots. Hindwing like the abdomen reddish-brown, hindwing in the apical portion of the costal margin whitish with feeble beginnings of lines. Described from 1 ♀ from Paraguay, in the Berlin Museum.

E. quercifolia sp. n. (85 a) is bright coppery brown, in the costal half as far as behind the postmedian *quercifolia*, line strewn with blackish-brown; transverse lines black, double, punctiform, with white vein-dots between them, the subterminal line composed of a curved row of black dots partly exhibiting outside a few white scales: before the fringe a fine black limbal line, on the ends of the veins white dots being especially distinct before the somewhat undulating fringes of the hindwing. Hindwing somewhat duller brown, in the costal-marginal portion darkened, the postmedian line powdered with whitish, and with a feeble dark subterminal line. Described from a ♂ from Huayaba, in the Berlin Museum.

E. temperata sp. n. (85 a) resembles *quercifolia*, but it is duller brown, the transverse lines are single, *temperata*, undulatingly dentate with white vein-dots on the averted sides: the subterminal line is fine, darker; the limbal line and white dots on the ends of the veins are absent. Hindwing monotonously red-brown without markings. According to 1 ♂ from Novo Friburgo in the Berlin Museum.

E. bipuncta Schs. (85 i) is a small species with a lilac brown body and blackish dorsal tufts at the *bipuncta*, base of the abdomen; the brown forewing at the base darkened with a grey shadow through the cell and at the costal margin, with 2 black dots at the cell-end; the antemedian line is fine, undulating, the posterior transverse line in the upper half composed of dark vein-dots, in the lower half of white ones; subterminal line dark grey, undulatingly dentate, partly bordered with white. Hindwing light brown, at the costal margin grey with a dark grey subterminal shadow at the apex. Expanse of wings: 25 mm. French Guiana.

E. lixa Dogn. (85 k). Above yellowish-grey with a blackish submedian shadow at the base and double, *lixa*, dentate transverse lines with a thick discal dot between them; behind the postmedian line with dark dusting subcostally and between 2 and 5; small subterminal internerval lunae bordered with white. Hindwing yellowish-grey, at the apex blackened with 2 subterminal dots between 6 and 7. Expanse of wings: 19 to 21 mm. French Guiana.

E. minuta Dogn. is monotonously light ashy grey, on the forewing only with a subterminal row of *minuta*, very feeble brownish internerval dots. Expanse of wings: 25 mm. According to 1 ♀ from Paranapanema (São Paulo, Brazil).

E. guttularis Wkr. (85 a) is again allied to the *zurcheri*-group. Above brown, in the costal portion *guttularis*, as far as the whitish subterminal band darker with fine black double lunular transverse lines and double black discal dots; subterminal line composed of ashy grey small internerval spots. Hindwing brown, costally somewhat darkened by grey with the beginnings of whitish lines. A common species widely distributed from Mexico to Brazil.

- subguttularis*. **E. subguttularis** Dogn. (85 a) is very similar, larger, somewhat more slender, the posterior transverse line treble, the area behind the discal dots lighter, the broad white subterminal band only very feeble. Venezuela, Colombia.
- laurena*. **E. laurena** Schs. (85 a). Forewing brown, at the costal margin beginning from the second quarter and at the apex grey or flesh-coloured white, the median vein and its branches black; in the light apical portion the veins are brownish; transverse lines in the dark portion of the wing indistinct, in the light portion more distinct, partly double with dark vein-dots, the most distinct is the notched subterminal line. Hindwing brown, at the costal margin and apex lighter greyish-white with nebulous beginnings of lines. From Guiana and the Amazons, before me from Pebas.
- brumosa*. **E. brumosa** Dogn. (85 k). Body and wings light ochreous, forewing at the costal margin brown, the cross-vein and postmedian spots between 3 and 5 likewise brown, behind them follows a white angular line; the white subterminal line disappears before the inner angle, before it between 6 and 7 a white spot. Hindwing at the costal margin likewise brownish. Expanse of wings: 24 mm. São Paulo de Olivença (Amazons). —
- tripunctata*. f. **tripunctata** Dogn. shows below the white subterminal spot 2 more white spots, the white postmedian line already terminates below the costal margin. Monte Christo (Amazons).
- fallacia*. **E. fallacia** Dogn. Anterior body and forewing brown, abdomen more yellowish-red; on the forewing a subterminal stripe, the veins and cross-vein excepting 5 are black, the subterminal stripe and vein 6 thicker and thereby parting the wing in its length; the anterior transverse line is black, a posterior line white; a postdiscal pale yellowish-red brightening between 4 and 6 as far as the margin; the real postmedian line is double only at the costal margin, then interrupted and only appearing again between 4 and 6 and at the inner angle; a white marginal line is thickened at both its ends. Hindwing light brown, at the costal margin blackened, with the beginning of a light marginal line. Expanse of wings: 27 mm. French Guiana.
- falsifica*. **E. falsifica** Dogn. (85 k). Forewing yellowish red-brown with a black longitudinal stripe on the submedian fold as far as the subterminal line; the cell and behind it between 5 and 6 strewn with black, these veins as well as 8 and 9 likewise black; the double subterminal line is filled with light yellowish and is bent to the centre of the inner margin; apex blackened; the anterior transverse lines only marked at the costal margin; Hindwing blackish-brown with the beginnings of a few lines. Expanse of wings: 30 mm. Venezuela.
- marginata*. **E. marginata** Schs. (85 a). Brown, forewing scantily scaled, with dark veins, between 5 and 6 behind the cell strewn with blackish, with a postmedian double, undulatingly dentate line interrupting the veins with light and extending in a large bow to the centre of the inner margin; subterminal line parallel to it, blackish, outside finely bordered with light yellowish, at the margin a light, then a black fine line. Hindwing brown, the light subterminal line almost extends to vein 4. Very common and widely distributed from Mexico to Panama, at the latter habitat somewhat lighter.
- libnites*. **E. libnites** Drc. is allied to *marginata*, the forewing is scantily scaled light reddish-brown with but one black stripe from the cell-end to the subterminal line, below the cell-end with a large yellowish-white spot, a smaller one nearer to the distal margin, the undulating lines as in *marginata*. Hindwing light yellowish-red, apex and distal margin darker brown. From Teapa (Mexico).
- jeba*. **E. jeba** Schs. is very closely allied to the preceding species, but much darker. Body reddish-brown. Forewing brown, at the base, between 2 and 3 near the cell, in the cell and between 5 and 9 as far as the subterminal line thickly strewn with black and brown, the brown anterior transverse lines only visible at the costal margin; postmedian line as in *marginata*, but between 5 and 6 interrupted by a light spot, behind it between 3 and 5 a lighter area; the lunular blackish subterminal shadow is bordered with lilac grey, the broadest at the apex. Hindwing brown, at the distal margin shaded with black, with a white subterminal line which is the most distinct at the apex. The ♀ is less black, more smoky. Expanse of wings: 23 mm. ♀ 30 mm. Costa Rica.
- sylpha*. **E. sylpha** Dogn. (85 k). Body and wings yellowish red-brown, mesothorax and abdomen above browner; the veins in some places, especially at the margin darker brown; of the anterior transverse line only a brown spot at the costal margin is visible, the postmedian line dentate with yellowish vein-dots behind it; subterminal line pointedly dentate, the dents receding far on 5 and 9, before it at the inner margin between 3 and 5 as well as between 6 and 9 one light spot each; fringes on the veins crossed by light. Hindwing reddish-yellow with the beginnings of lines at the costal margin, the subterminal line dentate as far as the anal angle, the strongest dents between 6 and 5, and 3 and 2. Rio Tapajoz (Amazons).
- indentata*. **E. indentata** Schs. (85 k) also belongs yet to the same group. Body and wings light yellowish reddish-brown; forewing with a whitish antemedian spot and a dark brown stripe from the base along vein 2 as far as the centre; the dark antemedian line is double and extends from the costal margin to 2; the exterior half of the cell and the space between 2 and 6 as far as the postmedian line lilac brown, the space between 5 and 6 behind the cell is still darker; the dark postmedian line is strongly incurved on 2 as far as the dark longitudinal stripe, and it is directly followed by an undulating line and behind it a dark shadow, both

of which are interrupted between 5 and 6; a subterminal grey shadow in a whitish area. Hindwing with a curved grey subterminal shadow. Expanse of wings: 26 mm. Costa Rica.

E. farina Schs. Forewing light brown, basally darker, the fine antemedian line at the costal margin *farina*, bordered by reddish-grey, the cross-vein and vein 6 as far as the postmedian line dark brown, the velvety brown posterior transverse line double, above 3 filled with reddish-grey; near the apex an oblique velvety brown costal-marginal streak; subterminal line shaded with dark, near the apex fine and dentate, at the anal angle a white spot. Expanse of wings: 29 mm. French Guiana.

E. farinula Dogn. (85 k) is somewhat smaller, above more brownish-ochreous, the bases of the costal *farinula*, margin and of the submedian broad black, at the cross-vein 2 black dots, the upper one thicker; transverse lines fine black, the anterior line irregular, rather indistinct, the posterior line double, the subterminal line dentate. Hindwing more brownish, only at the costal margin ochreous with the beginnings of 2 lines. Expanse of wings: 27 mm. French Guiana.

E. cacopasa Dyar (85 b). Forewing brown, before the double antemedian line, behind the cross-vein *cacopasa*, between 4 and 6, and at the distal margin lighter, the submedian somewhat strewn with white; at the cross-vein a black angular streak; postmedian line indistinct, somewhat darker brown, double with vein-dots, the interior dot between the costal margin and 7 being a very oblique black streak; subterminal line black, the thickest below the costal margin. Hindwing very long and narrow with a somewhat extended anal angle, before the light brown margin with a jet-black, inwardly faded marginal shadow, the dark subterminal line extends to 5. Mexico.

E. suramis Schs. (85 b) has still narrower forewings with a pointed apex and very oblique margin; *suramis*, brown, basally darker, with black veins strewn with white, the anterior transverse lines curved, composed of small brown spots, a chestnut-brown dentate median line despatches in the cell a streak to the cross-vein, the area behind it as far as the postmedian line liver-brown, between 5 and 6 and at the inner margin apricot-coloured reddish; postmedian line indistinct, between 5 and 2 bordered with a lighter reddish tint; apical third of the costal margin dark brown; behind the dark subterminal shadow the margin is yellowish-red. Hindwing as in *cacopasa*. Expanse of wings: 30 mm. Guatemala, also 1 ♀ from Sa. Catharina (Brazil).

E. aldegondes Schs. (85 k). Forewing cinnamon reddish-brown, at the cell-end and before the subterminal *aldegondes*, line lighter claret-coloured, transverse lines indistinct, more rusty brown, the median line with black vein-dots; the postmedian line consists of short black and white vein-streaks, between 6 and 4 as a straight black line, below 4 undulating to the inner margin, outside accompanied by a rusty brown line; subterminal line very thick, black, behind it a rusty brown marginal line. Hindwing at the costal margin, apex and distal margin as far as 3 mixed with greyish-white, with a thick black undulating subterminal line. Expanse of wings: 30 mm. Rurrenabaque (Bolivia).

E. daltha Schs. Forewing dark brown, finely strewn with white, with a blackish-brown streak at *daltha*, the base of the cell and a similar spot in the upper cell-angle; the double transverse lines finely dentate, double; the undulatingly dentate subterminal line is bordered with white at the apex, at the anal angle there is a small white spot. Hindwing dark brown with a blackish-brown subterminal line at the apex and traces of a postmedian line. Expanse of wings: 27 mm. Dutch Guiana.

E. sura Schs. (85 b) is rather scantily scaled, unicoloured dark smoky grey with a darker cell-end *sura*, streak and traces of very faint whitish transverse lines, the posterior line with diminutive white vein-dots; small, faint, lighter, diffuse subterminal spots. Hindwing with traces of a darker median shadow. Castro, Parana (Brazil).

E. retritita sp. n. (85 b). ♂: body brown, thorax and anal hair blackish. Forewing scantily scaled, *retritita*, grey with a dark cell-end streak and feeble darker oblique transverse lines. Hindwing with a whitish spot at the apex. The ♀ is still lighter, with shadow-like markings, also on the body light grey. According to a couple from Sul de Minas (♂) and Casa Branca (♀), Brazil. Types: ♂ in the Coll. HOPP, Charlottenburg, ♀ in the Berlin Museum, in the Coll. STAUDINGER.

E. centuncula sp. n. (85 b) is very closely allied to *sura*, but smaller, of a much stronger structure, *centuncula*, with a very stout abdomen, on the body and wings smoky grey with somewhat more brownish veins, darker cell-end streaks and a broad, feebly darker postmedian shadow which is only more distinct at the costal margin. Hindwing not marked. According to a ♂ the habitat of which is not stated, in the Coll. STAUDINGER in the Berlin Museum.

E. captiosa (85 b) is larger than *sura*, body blackish-grey, wings somewhat lighter, rather scantily *captiosa*, scaled, with slightly darker veins and a black cross-vein streak; the two median transverse lines are only noticeable as very faint darker shadows; subterminal line more distinct as a dark, undulatingly dentate nebulous line, interrupted between 5 and 6, this space beginning from the cell-end darker. Hindwing with traces of the beginnings of 2 shadow-like lines at the costal margin. According to 1 ♂ from South Brazil in the Berlin Museum.

E. pastica Schs. Forewing dark grey, the veins feebly strewn with light brown, at the cell-end a small *pastica*, red-brown spot with a black dot therein; white postmedian vein-dots, at the margin between the veins small

white lunae. Hindwing dark greyish-brown, at the costal margin strewn with white, with an irregular whitish subterminal line. Expanse of wings: 23 mm. French Guiana.

falsaria. **E. falsaria** Dogn. (85 k). Body and wings light brown, the blackish transverse lines on the averted sides strewn with white, the posterior line dentate, between them at the cell-end 2 black dots; at the margin there are black small internerval spots outside bordered with white. Expanse of wings: 22 mm. Sao Paulo de Olivença (Amazons).

terranea. **E. terranea** Btlr. is unknown to me. Wings light reddish-brown, powdered with a dull grey. Forewing with a postmedian row of black vein-dots forming two bows, at the base of the fringe with a light line. Hindwing basally lighter brownish-white. Expanse of wings: 1 inch. Serpa.

subterranea. **E. subterranea** Dogn. Forewing light yellowish-brown with 2 black discal dots and a subterminal row of black vein-dots, between 5 and 6 removed inwards, besides with traces of a postmedian line. Expanse of wings: 24 to 25 mm. French Guiana.

debilis. **E. debilis** sp. n. (85 c) is larger, very pale yellowish-brown, with fine darker veins and an oblique dark cross-vein streak; antemedian line almost vertical to the inner margin, postmedian line feebly curved, outside lighter, the subterminal line feebly traceable at the apex. Hindwing somewhat lighter, body somewhat more yellowish. According to 1 ♂ from Colombia in the Coll. STAUDINGER in the Berlin Museum.

detrita. **E. detrita** sp. n. (85 c) is much larger than *debilis*, the apex of the forewing more pointed, the colouring the same, the antemedian line slightly curved, the postmedian line less curved, but more distinctly angular on 8, outside not lighter; the subterminal line is somewhat more distinct. Hindwing somewhat darker, the body also darker, more brownish. According to 1 ♂ from São Paulo (Brazil) in the Berlin Museum.

falsa. **E. falsa** Schs. Body and wings light brown, forewing basally feebly darker and with a broad shadow through the cell; at the cell-end a black dot, behind it the double angular postmedian line, between the cell-end and apex some black striae, at the margin a row of black internerval dots. Expanse of wings: 22 mm. Castro, Parana (Brazil).

exigua. **E. exigua** Btlr. Wings sooty brown, towards the margin lighter, forewing with 2 parallel transverse lines between which the median area is darkened by blackish-brown above the median, with 2 parallel, undulatingly dentate, brown postmedian lines; a subterminal row of black spots, behind them at the margin brown dots. Hindwing at the apex blackened with the beginning of a whitish line. The ♀ is lighter, excepting the dark spot of the median area more indistinctly marked. Expanse of wings: ♂ 21, ♀ 22 mm. Rio Jutahi, Rio Purus (Amazons).

zemira. **E. zemira** Dre. (85 c) is a small brown species, easily discernible by the very strong, round, velvety black discal spot of the forewing, the costal-marginal portion of the forewing being lighter brown, at the apex almost whitish; the veins especially in the median area striped black, the anterior transverse line rather indistinct, the posterior line double, broken up into dots; below the cell there is a black basal ray; undulate line composed of small, feeble, darker internerval spots. Hindwing lighter, at the apex with blackish spots. Colombia.

mizera. **E. mizera** sp. n. (85 c) is very similar to *zemira*, darker, the costal margin only in the median area little lighter, the apex not lighter at all; the double antemedian line pointedly projects on the median very far towards the margin, the interior portion of the postmedian line is thick black, coherently undulatingly dentate, the exterior portion much feebler and brown; discal spot punctiform; the feeble subterminal line likewise represents a coherent brown line. Hindwing as in *zemira*, before the small black apical spot with the beginning of a double postmedian line filled with a lighter colour. Described from 1 ♂ from Thomar in the Coll. STAUDINGER in the Berlin Museum.

kotzschii. **E. kotzschii** sp. n. (85 c) is somewhat larger than the two preceding species, with the same thick velvety black discal spot as in *zemira*, but by the scheme of markings more similar to *marginata*. Forewing brown, costally somewhat lighter, with a black submedian stripe and an undulatingly dentate double antemedian line, the veins in the disc partly black, the double postmedian line feeble, only below the costal margin more distinct and deeper blackish-brown; the undulating line consists of small black internerval spots situate between 6 and 10 in a white halo, the uppermost black spot forming a large subapical spot; before the fringe a fine red-brown limbal line. Hindwing in the anal-marginal portion with somewhat more reddish hair, apically at the margin blackened, before it at the costal margin with the beginning of a feeble light postmedian line. According to 1 ♂ from Sa. Catharina (Brazil), type in the Coll. WERNICKE, Dresden.

lanceolata. **E. lanceolata** Dogn. is on the forewing reddish yellowish-brown, with double transverse lines which are parallel and very pointedly dentate, particularly the postmedian line in the shape of very long „points of lances“; they are darker brown, in the upper half more distinct by whitish irroration, all with their points turned outward between the veins; the fifth subterminal line is less pointedly dentate; at the cross-vein there is a very thick black dot. Hindwing with 3 apical darker lines situate in white-strewn surroundings. Expanse of wings: 25 mm. French Guiana.

E. palma Schs. (85 k). Forewing light brown, a large triangular area at the base of the costal margin *palma*. strewn with metallic scales, at the cell-end with a large velvety black spot, behind which a dark brown shadow extends to the double partly dotted undulating postmedian line; the dark brown subterminal line is undulate dentate, surrounded by whitish from 5 to the costal margin. Hindwing light brown with traces of a dark subterminal shadow. Expanse of wings: 21 mm. French Guiana.

E. attenuata Schs. (85 k) has dark brown forewings with a small dark brown spot below the base of *attenuata*. the cell and a round velvety black cell-end spot, anterior transverse line double; shaded with grey, posterior line single, very fine with a yellow-reddish shadow behind it, the postmedian area is lighter with a broad grey subterminal shadow in which there is a row of blackish-brown spots, before the uppermost of which a dark brown shadow is to be noticed. Hindwing dark brown with a whitish subterminal stripe at the costal margin. Expanse of wings: 21 mm. Variable in the more or less light ground-colour, also in the distinctness of the marking and the size of the discal spot which may be reduced to a streak.

E. tenuata Dogn. is allied to *attenuata*; forewing brown, basally blackened and strewn with white, with *tenuata*. fine irregular transverse lines and 2 black discal dots; posterior transverse line angular, inside shaded with black, outside bordered with white, behind it with a fine black, undulately dentate line; subterminally the veins 7—10 and the cellular spaces between them are blackened; the subterminal line is composed of small black spots bordered with white and, between 5 and 2, on both sides dusted with black. Hindwing lighter brown, at the apex blackened. Expanse of wings: 22 mm. Sao Paulo de Olivença (Amazons).

E. fasciolata Btlr. has remained unknown to me; forewing red-brown, in the discal area and a subapical *fasciolata*. stripe brown strewn with white, and at the cell-end with a brown streak bordered with black; postmedian line double, dentate and filled with whitish, the subterminal line is also composed of a row of black, white-edged small spots, as in the preceding species. Hindwing somewhat greyer with a dark-shaded subterminal line. Amazons.

E. bibiana Stoll is a not identified species from Surinam; dark brown, with 3 black antemedian transverse *bibiana*. lines, at the cell-end with a black discal streak, the slightly curved postmedian line is outside bordered with a somewhat lighter colour, before the subterminal line composed of small black internerval lunae at the costal margin with a short black subapical spot. The larva is figured by STOLL as brown with yellow longitudinal stripes with numerous bristles set with small black hairy knobs at the ends. It is reported to live on Guayava like the processionary caterpillars, jointly pupating in roll-shaped webs.

E. dentilinea sp. n. (85 c) resembles the figure of *bibiana*; browns trewn with purple grey, basally below the *dentilinea*. cell with a short black longitudinal streak, behind it with a double notched antemedian line, the postmedian line being fine, undulately dentate, slightly projecting between 3 and 4 and between 7 and 9, at the cell-end with a black thick discal streak; subterminal line composed of small black outside light-edged internerval spots receding far between 4 and 6 and being separated below the costal margin by white irroration from a black subapical spot before it. Hindwing at the costal margin lighter purple grey with a short black median line, subterminal line irregular, extending to the anal angle. Described from 1 ♀ from Sao Paulo in the Berlin Museum. Connected by *combusta* with the *ogenes*-group.

E. onoba Drc. (85 c) is a peculiar species not being allied with any other species. Rust-brown, strewn *onoba*. with a somewhat darker colour, especially in the basal two thirds of the forewing; no transverse markings except the postmedian border towards the somewhat lighter marginal area; at the cell-end 2 thick white dots finely surrounded by a darker colour, separated by an orange patch crossing the cell-end. Hindwing in the costal portion whitish dusted with a bluish-grey, with the beginnings of 2 lines of the ground-colour therein. fringes yolk-colour, basally mixed with orange; Peru; Colombia, from Mocoa in the Coll. HOPP.

E. inconspicua Schs. has a dark brown body, on the thorax feebly mixed with dark grey; forewing dark *inconspicua*. brown, at the cell-end with 2 black dots above each other, with a postmedian row of small dark greyish-brown, very indistinct spots; of a similarly coloured subterminal line only traces are visible. Hindwing blackish-brown, at the costal margin dark brown. The inner margin of the forewing projects rounded, the costal margin of the hindwing is straight as far as vein 9, then angular and oblique, at the distal margin rounded. Expanse of wings: 35 mm. Panama, Chiriqui.

E. definita Schs. Head and thorax dark grey, tegulae outside reddish-brown, abdomen dark brownish- *definita*. grey. Forewing very dark violetish-brown, basad with a reddish-brown spot, median area below the cell and the inner margin light yellowish red-brown; the irregular interrupted antemedian line is reddish-yellow, the similarly coloured postmedian line very fine, finely undulate, hardly visible in the costal half, in the light portion of the wing before it with a darker line; subterminally between 3 and 6 there are 3 small white spots with fine white lunulae behind them; at the ends of the veins with light reddish-yellow dots. Hindwing dark slate-colour, in the costal marginale portion dark violetish-brown with a feeble light median line to the inner margin above the anal angle; the costal margin of the hindwing is deeply concave, then it extends obliquely to 7. Expanse of wings: 33 mm. Costa Rica (Juan Vinas; Sixola).

- sigurda*. **E. sigurda** Schs. is a much smaller species with an almost straight costal margin of the hindwing, then obliquely as far as below 7, below it the distal margin is rounded. Body lilac brown, only the thorax reddish-brown. Forewing dull reddish-brown with yellowish-red lines, the anterior line straight, the thick discal streak blackish, the postmedian transverse line is outside accompanied by a fine, more oblique line extending from above 5 to the apex; the fine moon-spotted subterminal line runs from 6 to the inner margin near the anal angle. Hindwing lilac brown, at the costal margin dull reddish-brown with a faint light subterminal line. Expanse of wings: 28 mm. Costa Rica.
- modesta*. **E. modesta** Drc. (85 c). Forewing reddish-brown, strewn with violettish-grey, especially basad and at the inner margin, with a postmedian line composed of very fine blackish dots, and with thicker subterminal spots, both receding between 4 and 6. Hindwing somewhat lighter, at the costal and distal margins dark violettish-grey with a fine darker spotted subterminal line. Costal margin of hindwing at the apex pointedly extended, at the costal margin before and behind the middle with 2 pointed dents. Panama; Colombia.
- sonia*. **E. sonia** Schs. Body brown, on the head and thorax strewn with reddish-yellow, abdomen with a darker dorsal tuft. Forewing brown, strewn with reddish-yellow, in the median area and at the distal margin darkest, with small whitish basal spots and dark small spots at the costal and inner margins behind it; the dark brown transverse lines are undulate, on the averted sides bordered with whitish, the posterior line finely dentate, with a yellowish-reddish lunular line behind it, at the cell-end an irregular black spot; between veins 4 and 5 a reddish-yellow stripe, with subterminal dark brown spots outside bordered with reddish-yellow, before them between 5 and 7 lilac-white spots, above 7 a dark streak. Hindwing brown, in the costal portion strewn with grey and with dark brown spots, a short whitish subterminal line at the apex. Costal margin of hindwing short, concave, then oblique as far as 6, below it rounded. Expanse of wings: 28 mm. Costa-Rica.
- talma*. **E. talma** Schs. is a tiny species, with dull smoky grey body and wings, on the forewing with a darker spot at the cell-end and an indistinct darker postmedian line and subterminal line. Fringes with small reddish-yellow dots at the ends of the veins. Expanse of wings: ♂ 27 mm, ♀ 43 mm. French Guiana.
- carola*. **E. carola** Schs. is brown on the body and wings, with darker brown, white-spotted transverse lines, behind the postmedian line with a feeble lilac grey shadow near the costal margin, at the cell-end with a hardly visible darker streak; the dark subterminal line is distantly remote from the margin and does not reach to the inner margin. Hindwing with darker fringe. Expanse of wings: 33 mm. Costa-Rica.
- umbrosa*. **E. umbrosa** Dogn. is somewhat like *carola*. Forewing chestnut-brown, at the base of the costal margin dusted with blackish, also in the cell and on the first half of the submedian fold, from here in a straight oblique shadow to the costal margin before the apex and a parallel subterminal one behind it. Hindwing lighter and less reddish, at the costal margin with long hairs. Expanse of wings: 37 mm. Cali (Colombia).
- brunnea*. **E. brunnea** Schs. is a very small species described as *Ocha*. Above dark brown, on the forewing with 2 indistinct, feebly white-dotted transverse lines and an irregular submarginal row of small black spots, very feebly bordered with grey. Expanse of wings: 20 mm. Castro, Parana.
- casia*. **E. casia** Dogn. described from but 1 ♀ from the Songo (Bolivia) with an expanse of 54 mm. Above light lilac-grey, on the forewing strewn with reddish cinnamon-colour, especially in the basal area, at the inner margin and postmedianly, with darker lilac-grey transverse lines, behind the antemedian line with a fine, hardly visible cinnamon-brown parallel line; the subterminal line recedes as usually between 4 and 6. Hindwing lilac-grey, in the costal portion as far as the postmedian line strewn with reddish cinnamon-colour; veins feebly yellowish.
- rubrica*. **E. rubrica** sp. n. (85 d). Cinnamon reddish-brown, basad and at the costal margin feebly dusted with lilac grey, with 3 fine blackish transverse lines, the first extending through the black discal dot, the postmedian line receding towards the cell-end, the subterminal line composed of small black spots which are outside partly white-pupilled. Hindwing with a feeble blackish postmedian shadow behind which it is somewhat lighter. From 1 ♂ from Thomar in the Coll. STAUDINGER (Berlin Museum).
- quassa*. **E. quassa** sp. n. (85 d) is not dissimilar, but darker brown, the transverse lines very fine double, at the cell-end 2 black dots above each other, the subterminal line forming more an undulately notched line. Hindwing blackish-brown. From 1 ♂ from Sul de Minas (Southern Brazil). Type in the Berlin Museum.
- artata*. **E. artata** sp. n. (85 d) is still smaller than the preceding ones, more greyish-brown, the transverse lines double, as in *quassa*, but the portions, especially the postmedian ones, distantly separated, between both another indistinct median line; subterminal line more in the shape of small spots, outside edged with whitish. Hindwing in the anal-marginal portion lighter. 1 ♂ from Thomar in the Coll. STAUDINGER (Berlin Museum).
- canifascia*. **E. canifascia** Wkr. I had unfortunately no access to the description of this species which is neither present in Washington.
- confusa*. **E. confusa** Wkr. I only know from the insufficient description by WALKER, and can therefore not give my opinion upon its position. Forewing light reddish-brown, strewn with brownish red, with several incomplete.

undulating brown bands; fringes between the veins white-spotted. Hindwing along the veins reddish and with white fringe. Expanse of wings: 17 lines. Brazil.

20. Genus: **Nesara** Wkr.

This genus which is generally better known by the name of *Ocha* Wkr. is anatomically in no way separable from *Euglyphis* and therefore really not justified; nevertheless we keep it up as a habitual group; the species are at best to be separated by their small size, their relatively slender body and broad round wings. The species are mostly very similar, difficult to distinguish, and some of them may have to be cancelled as synonyms.

Genotype: *N. apicalis* Wkr.

N. casada Schs. (85 e). Forewing yellowish, above the median as far as the posterior transverse line *casada*, and at the distal margin shaded with violet, with a dark brown basal half of the cell; the 3 transverse lines are brown, the anterior line introangular above the inner margin, a median one turns lighter at the costal and inner margins, the postmedian line close behind it is double; at the cell-end 2 black dots; between 5 and 6 a dark brown shadow extends to the subterminal line, above it there is a purely yellow area; the subterminal line itself is dark brown only between 6 and 8, the rest of it irregular, at the costal margin inside shaded with brown, in the lower half only marked by violet shading. Hindwing light yellow with 3 brown costal-marginal lines. Expanse of wings: 24 mm. Costa-Rica.

N. fumicosta sp. n. (58 d) is similar to *casada*; forewing light ochreous, but at the costal margin only *fumicosta*, hardly as far as below the upper edge of the cell and from there along 9 to the distal margin dusted with violetish-grey, and narrowly the distal margin in the upper half; in the yellowish portion there are 5 feeble oblique brownish ochreous transverse lines visible, at the cell-end 2 black dots; fringe in the upper half speckled with brown; the dark spot between 5 and 6 is entirely absent. Hindwing yellowish-white, without markings. Peru. Type: 1 ♂ in the Berlin Museum.

N. pallida Btlr. (= *patara* Drc.) (85 d) is probably the same species as *casada*, but of a more gravel-yellow ground-colour without the lilac irroration, the postmedian transverse line reddish-white, the spot between 5 and 6 rusty red; inside shaded with black. Hindwing lighter; from the Rio Negro (Colombia); DRUCES *patara* probably refers only to a very pale whitish specimen; the latter originates from South East Peru: Santo Domingo.

N. caramina Schs. (85 e) is ochreous brown on the body and more yellowish on the abdomen. Forewing *caramina*, above the median and vein 4 smoky grey, below it ochreous brown, the whole wing strewn with white, more intensely so in the grey portion, with brown median and postmedian transverse lines; the whitish subterminal line incurved between 4 and 7 with a curved ochreous red spot behind it; a similarly curved white submarginal line, with a brown filling at the margin in the concavity; apical veins white, at the cell-end 2 black dots. Hindwing yellowish with a brownish-grey double apical shadow. The ♀ is more unicoloured yellowish red-brown, hindwing distally more intensely shaded with brown, with a lighter subterminal line. Costa-Rica.

N. lemoulti Schs. Anterior body and forewing light grey, scantily strewn with black, with a brownish *lemoulti*, longitudinal patch from the base through the cell and between 3 and 6 to the white subterminal line which forms 3 black-filled lunulae above 6; between the undulating transverse lines, the anterior one of which is double, with 2 black cell-end dots. Hindwing and abdomen reddish-yellow; hindwing with a grey costal-marginal portion with the beginnings of 2 brown lines and a dark apical streak. Expanse of wings: 23 mm. French Guiana.

N. dacasa Dogn. (85 e). Above reddish ochreous, between the two blackish transverse lines with the *dacasa*, usual two cell-end dots and a black basal shadow below the cell; right behind the postmedian line begins, between 5 and 6, a crescentiform black shadow ending pointed on 3 at the margin; subterminal line incomplete. Hindwing with an irregular blackish marginal shadow. British Guiana.

N. laurina Dogn. (85 e) is smaller than the preceding species, and lighter yellowish, the markings *laurina*, brownish with much more numerous transverse lines and bands covering the whole wing; a broad median band is divided below the costal margin into 2 large crescents enclosing the 2 black cell-end dots; the very broad subterminal band is interrupted between 6 and 8, from 3 to the anal angle much narrower; basal and in the cell 2 more black dots each; fringe between the veins blackened. Hindwing only with a short apical line. Expanse of wings: 21 mm. French Guiana.

N. gorgas Schs. (85 f). Body light lilac brown; forewing above the median and vein 4 grey; below it *gorgas*, light brown; of the 3 fine darker transverse lines only the posterior line is more distinct, followed by a light line which is curved behind the cell, the cellular spaces between 4 and 8 behind it darker grey; before the white subterminal lunulae between 5 and 6 there is an orange brown spot; fringe speckled with dark brown. The yellowish hindwing is shaded at the costal margin, with short apical lines. Expanse of wings: 25 mm. Joinville.

N. ocruma Schs. (85 f). Forewing reddish-yellow, strewn with light reddish-brown; with 2 black dots *ocruma*, at the cell-end; between the rather indistinct postmedian line and the subterminal line, between 4 and 6, a large

dark violettish-brown spot, the margin behind it is dark grey, between 6 and 7 a black subterminal spot; the subterminal line itself is composed of light grey lunulae. Hindwing lilac brown, basad and at the costal margin dusted with reddish-yellow. Expanse of wings: 27 mm. French Guiana.

lauda. **N. lauda** Drc. (85 d) is apparently very variable; in the typical form the forewing is yellowish-white, finely strewn with reddish-brown, especially in the discal area, the transverse lines only indicated by contrasting colours between strewn and not strewn areas; at the cell-end 2 black dots with a more or less distinct white discal streak between them; between 5 and 6 a subterminal red-brown oblong spot, here the unstrewn whitish subterminal line recedes a little and it is inwardly more intensely shaded with red-brown; veins 6 and 7 more distinctly set off white, the margin especially between 4 and 7 broader and shaded with darker red-brown; behind a white limbal line the fringe between the ends of the veins is brownish. Hindwing light yellow, at the costal margin strewn with brown, with the faint beginnings of lines, the subterminal line apicad shaded darkest. In many specimens the costal portion is above the median and 4 dusted with violettish-grey in variable intensity; the most conspicuous specimens may be named: **duala** f. n. (85 d), they resemble *gorgas* and *caramina*. Mexico, Guatemala.

robustior. **N. robustior** sp. n. (85 d). Farther to the south *lauda* is replaced by a very similar, though invariably darker and more unicoloured species which is somewhat larger and stronger. Besides it is extremely variable. The principal form is ochreous with dense red-brown irroration. Markings almost the same as in *lauda* though fainter, the subterminal spots between 5 and 6 and the subapical spot light orange, the latter outside bordered with light. Hindwing much darker, almost like the forewing, the subapical spot being very prominent in *lauda* *fuliginosa*. is here very feeble. Espiritu Santo; type in the Museum Senckenberg. — f. **fuliginosa** n. (85 d) is light loam-coloured on the body, the wings are all over suffused with a greyish brown. Type: 1 ♂ from Pacho (Eastern *quindiensis*. Colombia) in the Museum Senckenberg. — f. **quindiensis** n. (85 d), from the Quindiu Pass, is still much darker, on the forewing suffused with steel-black, the median area at the inner margin deep bronze brown, in the centre dusted with purple grey. Hindwing almost quite black. Body fox-coloured. Type: 1 ♂ in the Mus. Senckenberg.

pocila. **N. pocila** sp. n. (85 e). Scheme of markings also exactly as in *lauda*, but it is much larger and inversely coloured with respect to its form *duala*: in the costal half light ochreous, in the proximal half below the cell and as far as 6 purple blackish, in the median area deep chestnut-red, of the same colour a spot between 5 and 6 which passes over subterminally into an orange stripe; the bordering of the median area on the averted sides whitish. Subterminal line whitish, in the ochreous portion inside shaded with blackish. Hindwing light yellow, subapically with 2 black spots. Body light ochreous, on the metathorax chestnut brown. Moeoa, Colombia. Type: 1 ♂ in the Coll. W. Hopp, Charlottenburg.

famata. **N. famata** Schs. (85 f). Forewing above light reddish-brown, with a dark basal streak, white apical veins and fine dark double undulating transverse lines, the postmedian line outside bordered with whitish; between 4 and 7 from the cell to the margin a dark shadow in which 3 small red-brown spots border inside on the white marginal line; a small dark subapical spot. Hindwing dark brown, at the costal margin lighter, enclosing the beginnings of whitish lines; fringe speckled with dark brown. Expanse of wings: 25 mm. Castro, Paraná.

majorina. **N. majorina** Schs. is larger than *famata*, the wings are more whitish, the markings yellowish ochreous, the large subterminal spot and the subapical spot of a bright ochreous, inwards dusted with lilac. Hindwing of a yellowish-white sulphur-colour, at the costal margin feebly lilac. Expanse of wings: 30 mm. Esteban Valley (Venezuela).

francesca. **N. francesca** Schs. seems to me to be extraordinarily allied to the form *duala* of *lauda*, but the ground-colour is a light reddish-brown, above the median and 4 light grey, basad below the cell with a white spot; transverse lines double, between the posterior line and the subterminal line with another white undulating line between 5 and the inner margin. Hindwing behind a brownish median shadow with darker veins, the apical part of the costal margin reddish-brown with the beginning of a light subterminal line therein. Expanse of wings: 28 mm. Costa-Rica.

niveipunctata. **N. niveipunctata** Dogn. (85 f). Forewing yellowish-white, with a small dark brown discal dot and a postmedian line formed of brown irroration and receding far between 4 and 5; between 7 and 10 subterminal brown irroration, below it between 7 and 6 a quadrangular pure white spot, and 3 white dots between 6 and 3 below it; before the speckled black-brown fringe a white line. Hindwing lighter. Expanse of wings: 24 mm. Sao Paulo de Olivença (Amazons).

laxta. **N. laxta** Drc. (85 f), described as *Dalcera*, unknown to me. The insufficient description runs as follows: forewing brownish-grey, from the costal margin to the inner margin traversed by undulating fine brown lines. Hindwing dark grey, basally lighter. Beneath grey without markings; body light grey, antennae and legs light brown. Expanse of wings: $1\frac{1}{4}$ in. Sarayacu (Ecuador).

apicalis. **N. apicalis** Wkr. (85 c). Forewing light yellowish-white with slightly darker transverse lines and 1 or 2 black cell-end dots; a blackish apical spot is divided by the white subterminal line which is broadly bordered with ruddle-red between 4 and 7 on both sides; below it the fringe is speckled with blackish; the median vein

and its branches partly finely blackened. Hindwing light ruddle-red, at the costal margin broadly yellowish-white; before the subterminal line feebly strewn with a darker colour. Brazil. The species is apparently rare and has no more been found. The figured ♀ was before me from the Berlin Museum. Mr. SCHAUSS has substantiated the determination.

N. lasthenia Drc. (85 e) is marked very much like *lauda*, but of a pure white ground-colour, the markings *lasthenia*. are indicated by extremely feeble blackish and yellowish-ochreous irroration, the median area is very feebly set off darker in the disc; the spot between 5 and 6 is greyish-black; the darkest is the subapical spot on the hindwing. Mexico.

N. macerra Schs. Forewing all white, only basad with a small brown spot, apicad with a large one. *macerra*. Hindwing yellowish, basad white, at the apex with a small brown spot. Abdomen golden yellow. Expanse of wings: 20 mm. Paso de San Juan (Mexico).

N. filamentosa Dogn. (85 f) is allied to *macerra*, also white with a double undulating median line of *filamentosa*. rusty brown atoms and a similar apical spot. Hindwing likewise apicad strewn with rusty brown, very narrowly also at the distal margin. Sao Paulo de Olivença (Amazons).

N. mita Schs. (85 f). Body and wings white, forewing with light yellowish reddish-grey markings, *mita*. 5 transverse lines, and a marginal shadow; median area at the inner margin similarly darkened; at the cell-end 2 black dots and subterminally between 5 and 6 black irroration; fringe above 4 dotted black. Hindwing with a black apical spot. Expanse of wings: 21 mm. French Guiana.

N. dalceroïdes Schs. (85 f). White as *mita*, but with a very characteristic median line which is divided *dalceroïdes*. below the costal margin in order to enclose the 2 discal dots, uniting again below 3 and being again divided at the inner margin; the fine postmedian line is very indistinct; a dark grey apical shadow and dark dots in the fringe. Hindwing at the distal margin greyish-brown, at the anal margin with 2 small spots of grey irroration. Expanse of wings: 26 mm. French Guiana.

N. oroyana Dogn. (85 f). Body pinkish-yellow; forewing white; through the cell as far as the margin *oroyana*. between 6 and 10 a chestnut-brown longitudinal spot enclosing a black dot in the lower cell-angle, outside as far as the postmedian line spotted orange; the brownish transverse lines are partly interrupted, dentate, the posterior line beginning from 6 double; at the margin a pure white area ending inside between 6 and 4, outside at the margin between 7 and 4; between 4 and the anal angle the marginal area is orange-yellow; the fine white subterminal line is interrupted in some places. Hindwing light yellowish with a brownish costal-marginal area. Expanse of wings: 25—29 mm. Peru, Amazons.

N. drucei Schs. (85 e). Body yellowish-white; forewing light reddish-brown, along the inner margin *drucei*. whitish, the brown transverse lines double; at the apex and between 4 and 6 small spots strewn with brownish; fringe speckled brown. Hindwing yellowish-white, at the costal margin brownish irroration. Expanse of wings: 23 mm. Sao Paulo.

N. tremula Schs. (85 f) is reddish-ochreous on the body, lilac brown on the thorax; forewing lilac brown, *tremula*. basally and subterminally with a reddish-brown tint, with yellowish-white transverse lines, the two median ones being double; at the base of the cell a black spot and at the cell-end the usual 2 dots; before the subterminal line there are small dark brown subapical spots; fringe speckled darker. Hindwing reddish ochreous, at the costal margin strewn with grey and brown. Expanse of wings: 18 mm. Dutch Guiana.

N. parva Dogn. is one of the smallest species of but 17 mm expanse. Wings white with grey markings: *parva*. on the forewing 5 parallel transverse bands, in the costal half regular, in the lower half irregular; at the cell-end an indistinct black dot; between 5 and 6 a darker spot; veins 2—5 partly grey. Hindwing with 3 parallel bands. French Guiana.

N. plicistriga sp. n. (85 e). Forewing very pale brownish white, at the costal and inner margins broadly *plicistriga*. smoked yellowish, traversed by numerous very fine grey lines; the antemedian line is double, at the inner margin very oblique towards the base, the postmedian line between 4 and 5 forming a large inward bow, the median area at the inner margin darkened grey; on the discal fold from the postmedian line to the margin a black streak; apical veins feebly darkened, fringe speckled blackish. Hindwing white, at the costal and anal margins feebly yellowish. Body light ochreous. According to 1 ♂ from Villavicencio (Colombia); type in the Berlin Museum.

N. plagiata Wkr. is unknown to me; dull reddish brown, forewing with several oblique very fine blackish- *plagiata*. brown notched bands, a blackish-brown discal spot, and very fine whitish spots. Hindwing of a much brighter colouring, with a short darker subapical band. Expanse of wings: 12 lines. Brazil.

N. albida Wkr. is likewise unknown to me. Founded upon a damaged ♂: whitish, forewing with a few *albida*. narrow brownish angular bands which are partly spotted black. Hindwing feebly hued with light brown. Expanse of wings: 10 lines. St. Domingo.

N. turpis Btlr. Sooty brown, forewing with a narrow angular catenary median band bordered with *turpis*. white; apically scantily strewn with white; the light subterminal line is zigzag-shaped; the dark fringe with white vein-dots. Hindwing lighter with a shortened subterminal band at the apex. Expanse of wings: 1 inch. Rio Jurua (Amazons).

21. Genus: **Hypopacha** N. & D.

This North-American genus contains but one small species forming the transition between the *Euglyphis* and the following *Malacosoma*. Shape of wings broad, costal margin straight, distal margin of hindwing rounded; antennae of half the length of the costal margin, not very long combed, in the ♀ serrate.

Type: *H. grisea* Neum.

grisea.

H. grisea Neum. (86 a). Grey, strewn with a darker colour, with thick blackish-grey transverse stripes which are irregularly dentate, the anterior one double, the posterior one double only below the costal margin, both filled with light; the subterminal line recedes distally in an angle and is inwards bordered with a somewhat lighter colour. Hindwing and abdomen lighter. Apparently very rare, from Arizona.

22. Genus: **Malacosoma** Hbn.

The American representatives of this genus having been dealt with at large already in Vol. II, p. 150, by Dr. K. GRÜNBERG, offer such uncommon difficulties that we feel infinitely obliged to Dr. H. G. DYAR for having complied with our request to overtake the elaboration of these species. They are likewise chiefly middle-sized forms with variably brown and yellow tints, with mostly 2 light or dark transverse stripes on the forewings. Like the North-American *Tolyte*, these insects also exhibit so great an individual variability whilst being evidently very closely allied that their delimitation is almost impossible for those not being well versed in the matter. Therefore the trial has been made to facilitate the determination by an analytical table, though for the reasons mentioned above it can only be regarded as a general and summary sketch. The anatomical and biological conditions of the species are entirely the same as those described in the Palaearctic Volume, so that we need not enlarge upon this matter here.

Type: *M. franconica* Esp. (palaearctic).

ANALYTICAL TABLE OF SPECIES.

I. Forewing crossed by light lines, at least in the male.

- A. Reddish brown, sexes similar, white lines of forewing straight, rather broad or shaded *americana* Harr.
- B. Dark brown, sexes similar, white lines of forewing narrow, more or less erenulate *fragilis* f. *azteca* Neum.
- C. Variable; pale lines yellowish in male, often with dark edges, more or less crenulate; female paler, more or less suffused with luteous
 - a. Grey-brown; female of the same shade but paler *fragilis* Stretch.
 - b. Male bright red-brown, female yellow or brown suffused *pluvialis* Dyar
californica Pack.
ambisimilis Dyar

II. Forewing crossed by dark lines in both sexes.

- A. Male pale yellow, female dark brown *constricta* Stretch.
- B. Male and female both pale yellow; lines more or less brown shaded between *luteimargo* Dyar
- C. Sexes similar, not pale yellow
 - a. Brown lines of forewing distinct and rather broad
 - α Apex of forewing round; lines non-crenulate *disstria* Hbn.
 - β Apex of forewing acute; lines somewhat erenulate *onissa* Dyar
 - b. Brown lines narrow or obsolete, more or less crenulate
 - α " Male dark brown, female yellow *pluvialis* f. *recenseo* Dyar
 - β " Male yellow, female darker *tigris* Dyar
 - γ " Male clay-color with the dark lines distinct but narrow *texana* Beutenm.

americana.

M. americana Harr. (= *decepiens* Wkr., *frutetorum* Bsdv.) (86 a). Sexes similar, soft red-brown, the lines of forewing white, broad, often shaded whitish between in the male. Larva with narrow whitish dorsal stripe edged with orange streaks, and blue spots on the sides, on wild cherry and apple. The larvae spin a large communal nest in the forks of twigs in the spring. This is the „American text caterpillar“. Northern Atlantic States.

disstria.

M. disstria Hbn. (= *drupacearum* Bsdv., *sylvatica* Harr., *thoracicoides* N. & D., *erosa* Stretch, *sylvaticoides* N. & D., *thoracica* Stretch, *perversa* N. & D., *astriata* Reiff, *anita* Reiff) (86 a). Brown and yellow, with dark lines on forewing, very variable; the various varietal names proposed are superfluous, referring to individual

variation only. Male yellow to brown, variously shaded; female generally yellow, the veins often brown-lined. Larva with round, often double, white segmental dorsal spots. The larvae spin no nest, but will congregate in masses on the tree-trunks. Found on oak and various forest trees. Northern United States from Atlantic to Pacific.

M. texana *Beut.* (86 a). Described as a form of *disstria*, but lacks the habitus of that species. Forewing *texana*. pale clay-colour, irrorate; lines brown, clear cut, without pale edges. Only males before me. I think it may be a good species allied to *tigris*. Female and larva unknown. Texas.

M. tigris *Dyar* (86 b). Both sexes yellow, irrorate, female more heavily so; lines brown, slender. faint *tigris*. or obsolete in the male; hindwing brown-shaded with central band. Larva on dwarf oak, without web, brilliantly marked with orange, the double lateral line slightly obliquely dislocated on the segments. Colorado. — *inducta* *inducta*. *Dyar* is a form more heavily dusted with red-brown, also in the male more heavily than in the normal female of *tigris*; hindwing darker than forewing.

M. fragilis *Stretch* (86 a). Red-brown, seldom chocolate brown, very variable; female usually largely *fragilis*. luteous, the white lines fading into the ground and leaving their dark borders as dark lines across the wing. Arizona, Colorado, Montana, Utah, Nevada, Wyoming, California. — **azteca** *Neum.* (86 b) is more chocolate *azteca*. brown, the sexes similar; lines pale, narrow, more or less crenulate. Mexico, widely distributed. — **mus** *Neum.* *mus*. is similar to *azteca*, wings greyer, often markedly irrorate with white. Utah. — **incurva** *H. Edw.* (= *discolorata incurva*. *Neum.*) is chocolate brown as *azteca*, but the wing invaded at the base and outer margin more or less with luteous whitish. Arizona, Utah. — **constrictina** *N. & D.* (= *lutescens N. & D.*) is an aberration of the male *constrictina*. with the lines of the normal female of *fragilis*. Arizona. — **perlutea** *N. & D.* has a very light yellow male, but *perlutea*. the specimens may be faded. Utah. Larvae with blue markings predominating, the orange reduced. In webs on aspen and various trees and shrubs.

M. luteimargo *Dyar* (86 b). Both sexes with wings luteous, the lines brown, crenulate, more or less *luteimargo*. shaded across. Hindwing brown shaded at base. Mexico. Occurs with *azteca*, but very different in colour and apparently without transitions.

M. onissa *Dyar* (86 b). Known only in the male. Large, brown, irrorate, the lines dark with traces of *onissa*. pale edges, the forewing pointed at tip, fringe checkered with white. Hindwing dark, uniform. Mexico (Zacualpan).

M. pluvialis *Dyar* (86 c). Male red-brown with distinct pale lines; female pale with narrow dark lines. *pluvialis*. Oregon, Washington, British Columbia. Larva with much orange, little blue, in webs on alder and other trees or bushes. — **recenseo** *f. n. Dyar* (86 c). Male dark brown, forewing irrorate and with narrow dark lines; female *recenseo*. yellow with dark lines on forewing. This new race occurs on the mountains of California (Truckee and Siskyou). Larva intermediate between *fragilis* and *pluvialis*, both blue and orange nearly evenly developed.

M. californica *Pack.* (= *pseudoneustria Bsdv.*) (86 c). Markings of *pluvialis*. Female more or less brown *californica*. shaded, when heavily so the lines are pale instead of dark. Larva black with red hairs. On live oak. California.

M. ambisimilis *Dyar* (86 c). Markings of *californica*. Larva with red hair dorsally, white subventrally, *ambisimilis* the body marked with wavy red lines and blue-white spots laterally. On various shrubs, not oak. California.

M. constricta *Stretch* (= *strigosa Stretch*) (86 d). Male light clay-yellow with slender dark lines; female *constricta*. brown, more or less whitish dusted and with brown lines with pale edges. Larva with orange dorsal stripe and tufts, lateral blue area and subventral white tufts. On deciduous oak, the egg-masses white, not brown as in all the other species. California.

23. Genus: **Heteropacha** *Harv.*

Only one small species with relatively narrow wings, distinguished by hairy eyes, shorter pectinate antennae, and scantily scaled entire-margined wings. On the forewing 6 and 7 on a short stalk; cells in both wings open; on the hindwing 6, 7 and 8 rise close together in the basal third.

Type: *H. rileyana* *Harv.*

H. rileyana *Harv.* (86 d). Dark brownish-grey, with darker veins, 2 irregular transverse lines edged *rileyana*. with a lighter grey, and a row of small dark subterminal spots; fringe checkered. Hindwing of same colour with a grey band in the centre of the costal margin. Missouri.

24. Genus: **Epicnaptera** Rbr.

This genus having been described at large already in Vol. II, p. 166, has also in North America a most variable representative. It is particularly distinguished by the ercunate margin on both wings. Apex of forewing acute, the round hindwing shows a strong basal cell from the upper edge of which 3 or 4 accessory veins run into the very convex costal margin.

americana. **E. americana** Harr. (= occidentis Wkr., earpinifolia Bsdv.) (86 d). A variable, small species, somewhat like the palaearctic *ilicifolia*. The nomenclatural form is red-brown with more or less extensive grey irroration and 2 blackish dentate transverse lines and small discal spots. — f. **ferruginea** Pack. is a somewhat smaller form without any grey irroration, so that the black transverse lines are more distinctly set off on the rust-brown ground. — **californica** Pack., on the contrary, is a lighter ash-grey, more southern form, with hardly any traces of brown; fringe more distinctly checkered with silvery grey. South California. — f. **mildei** Stretch (= roseata Stretch) shows a slight pink hue. — **dyari** Rivers shows light yellowish colour, only the inner-marginal portion being of a somewhat more pinkish-brown shade. The ♀ is still much lighter, almost creamy, with very faint markings. Hindwing with a distinct lighter band. Texas. The type is widely distributed in the other United States.

Corrections.

8. Family: Eupterotidae.

The American Continent harbours but one representative of these forms which are widely distributed in the African and Indo-Australian Faunae; according to its exterior and structure it undoubtedly belongs to this place. Up to the last years a number of other quite heterogeneous elements had been added to this family, but on their having been thoroughly examined they were cancelled again. So for instance some unquestionable Bombycids of the genus *Carthara* and its nearest allies belonged to this group, moreover those insects resembling *Apatelodes*, which now prove to be a separate family closely allied to the *Notodontidae* and which we shall introduce here for the first time as „*Zanolidae*“.

As to the only representative we may briefly refer to the detailed introductions in Vol. X, p. 417, and Vol. XIV, p. 293, where all the essential characters of these peculiar insects have been dealt with. We merely repeat here that they are mostly large insects with broad wings, with a short discal cell on both wings, part of vein 8 of hindwing being fused with the upper cell-wall, whilst vein 5 rises from the centre of the cross-vein; frenulum present, whereby the family is separated from the *Lasiocampidae* which lack it altogether. We know as much as nothing of the habits of the only American representative which has remained a great rarity — only very few specimens being known up to the present day.

1. Genus: **Preptos** Schs.

A lepidopteron of medium size with broad wings, straight costal and distal margins on the forewing, with a rounded inner angle; cell on both wings very short; antennae with very short pectinations and with hair-tufts at the base. The very short palpi droop somewhat and are covered with woolly hair. Abdomen shorter than hindwing. Only one Central-American, extremely rare species:

P. oropus Schr. (= *corax* Drc.) (86 e). Pale brownish, body with a dark greyish-black collar; wings *oropus*. with 4 or 5 grey median and postmedian undulate lines, forewing with the beginning of a grey antemedian line at the costal margin; behind the dark brown, very slightly curved subterminal line the marginal areas of both wings are darkened brown. Mexico (Jalapa) and Guatemala. The specimen figured from the Berlin Museum originates from Guatemala.

Original description of the form of the American *Eupterotidae*:

oropus Pr. Schs. Pr. Zool. Soc. Lond. 1892, p. 310.

9. Family: Drepanidae.

It is rather difficult to make general remarks about the propinquity and range of the *Drepanidae*, since their delimitation from the other families is very uncertain. Those reckoning the American *Cicinnus* in with the *Drepanidae* (KIRBY) will discover a good transition to the *Saturnidae*, at least if we remain in the American Fauna; but if the *Mimallonidae* with their larvae living in cases that are open on both sides are exempted and treated as a separate family, this connection is torn asunder, at least for the American Fauna, and in this case the family would be removed more to the *Thyrididae* exhibiting several resemblances in the neurulation (cf. STRAND, Vol. 2, p. 195, and WARREN, Vol. 10, p. 444).

The thorough elaboration of the *Mimallonidae*, in contrast with our former poor knowledge, easily shows how very appropriate and natural their separation from the *Drepanidae* is. In the American Fauna we then only need yet to consider the relations of the *Drepanidae* to the *Oxyteninae* which are only represented in the New World. In fact, the habitual resemblance between the American *Therinia* and many palaearctic genuine *Drepanidae* is by no means limited only to the light colour of the wings or to their shape. By the proportion of the uncommonly broad and large wings to the tiny abdomen which is by far exceeded by the anal angle of the hindwing, the prominently marked and coloured apex on the hindwing of many *Drepanidae* (*Macrocilix*, *Sewa*), the frequent exterior resemblance to *Urapteryx* (in *Ditrigona*), and other accords with distantly remote *Geometridae*, which can by no means be due to mimicry or exterior conditions (as for instance *Auzata semipavonaria* with *Ripula mahometaria*; *Canucha* with *Oxydia*; *Auzata superba* with *Problepsis* etc.), the South-American *Oxyteninae* are, to a certain degree, paralleled with the *Drepanidae*.

In addition there is the curious zoogeographical fact that the *Drepanidae* are entirely absent in the whole of South America, but represented there, to some extent, by the habitually similar *Mimallonidae*. There prevails an unmistakable exterior resemblance between many of these *Mimallonidae* and the *Oreta*-species from the groups of *O. variëgata*, *dissimilis*, *cervina*, *castaneata*, *jaspidea* etc., and also here we find the general law that certain formations being opportune for some reason or other develop from frequently heterogenous branches of their pedigree, at various places of our globe where certain conditions of life coincide, as for instance the Geometrid *Carthaea saturnioides* in Western Australia, where no *Saturnia* occur.

We may, however, readily assume the probability of close relations of the *Drepanidae* to the family of the *Notodontidae*. There is no doubt that several branches of the *Notodontidae* have developed in various directions: one branch, as we already mentioned in Vol. XIV, p. 402, to the *Sphingidae*, another branch to the *Ceratocampidae* resp. *Brahmaeidae*, a third to the *Dioptidae*, and a fourth to the *Drepanidae*. The latter branch has probably separated a very long time ago, for in the *Drepanidae* we meet with the majority of those qualities we are used to find especially developed in notoriously old families: i. e. a frequently most excellent adaptation to dead objects, whereas mimicry or frightening colours do not occur in a single case.

The larvae still exhibit the exact Notodontid shape and polymorphism: either humps, or horns or caudal spikes, sometimes 14 or 16 feet. The imagines are mostly copies of dry leaves, but sometimes also excellent imitations of little clods of earth or of birds' droppings. They are certainly not protected by sharp saps, and the few diurnal species flying in the sunshine therefore exhibit the swaying, rocking, doubling flight which makes the capture very difficult, as we see it for instance with the males of *Agria*, *Eudia*, *Orgyia*, *Pantana* etc., but which is generally not met with internally protected lepidoptera, such as the species of *Zygaena*. — The few American *Drepanidae* which, as we mentioned, are confined to the nearctic district, are all allied to palaearctic species. The statement that the palaearctic *Cilix glaucata* occurs in America, as for instance mentioned in HAMPSON'S Fauna of India *), is a mistake.

1. Genus: **Drepana** Schrank

As to the details about this genus we refer to Vol. II, p. 199, and Vol. X, p. 463. In America there is but one representative of these tiny insects which are chiefly developed in the palaearctic and Indian regions. They are distinguished from the other Drepanid genera by the presence of a broad and short accessory cell on the forewing which is somewhat falcately extended at the apex. The exterior and the biological conditions do not differ essentially from those of the European species.

- arcuata*. **D. arcuata** Wkr. (= *fabula* Grt.) (86 c). The wings are whitish straw-colour, darker shaded centrally, crossed by three or four wavy lines centrally and submarginally, and a strong even brown line that runs to the falcate apex. This is the common form from Nova Scotia and New York, but it also occurs in Canada, New Hampshire, Massachusetts, and Indiana; instead of the cell-end there is here a dot which is separated from the median line. — *genicula* Grt. is a darker yellow, less distinctly marked form in which particularly the median lines are faint, often somewhat smaller. — *grotei* B. & Benj. is the form belonging to it from Alaska with a dark brown ground-colour shaded with grey, broader and more faded lines and a much larger reniform macula. — *siculifer* Pack. is larger than *arcuata*, of a yellowish ground-colour, not dark shaded centrally, with a larger reniform macula, in this respect very similar to the European *falcataria*. California, British Columbia. — *alaskaensis* B. & Benj. is the Alaska-race of *siculifer* with more intense markings; besides the shading is more intense, so that the central area is considerably darker than the basal and marginal areas, whereby the total impression is quite different. Ketchikan (Alaska). Larvae on alder; green, subdorsal tubercles of joints 3, 4 and 6 prominent, a subdorsal brown line, more or less shaded across behind joint 6; head transversely banded.

2. Genus: **Falcaria** Haw.

Separated from the preceding genus only by the undulate outer margin of the forewing. The only species is the American representative of the European *lacertinaria* which is not separated from *Drepana* in Vol. II.

- bilineata*. **F. bilineata** Pack. (86 d). Whitish straw-colour to brownish yellow; two parallel brown lines across forewing, a minute discal dot, and more or less distinct brown strigae. Northern United States from Atlantic to Pacific; western specimens are often larger than eastern ones, but the difference is not so decided as in *D. arcuata*. — The form *levis* Huds. has the forewing smooth brownish yellow with the strigae faint or absent; besides it is generally smaller than the typical form. It may be partly a season-form. — *rampartensis* B. & Benj. is intermediary between the eastern *bilineata* and the European *lacertinaria*, but darker than the latter, blackish brown, with intense dark brown strigae, the lines as in the preceding form, the anterior line inwards lighter, with a whitish indistinct subterminal line, and red-brown and white dusting at the apex. The wings are somewhat less dentate. Ramparts (Alaska). — *hudsoni* B. & Benj. corresponds to *levis*, it is somewhat smaller and without the strigae. From the same habitat at the same time. Larva dark brown, somewhat obliquely whitish shaded on the sides, with prominent tubercles, giving a rough appearance. It lives on birch.

3. Genus: **Oreta** Wkr.

Somewhat larger and stronger species exhibiting particularly in the Indian Region a profuse development of forms (cf. Vol. X, p. 479). They chiefly differ from the preceding genus in the longer and narrower accessory cell.

- rosea*. **O. rosea** Wkr. (86 e). Forewing pinkish-brown with 2 shaded darker lines, the outer angled subcostally, with small dark irrorations; forewing with a broad submarginal band, often containing two round dark dots above tornus; hindwing with the outer half yellow, except apically. — In *marginata* Wkr. the basal rosy of forewing is more or less replaced by yellow. — *irrorata* Pack. shows no yellow at all, but it is rosy throughout. Northeastern North America. Larva on Viburnum; brown, the dorsal region paler; in the middle two dark lateral angles nearly meeting dorsally. Head notched, anal segment produced into a long spinous tail.

O. adona Streck. The author mentions it from Florida: according to the description it entirely resembles the palaearctic *O. extensa* Wkr., which it may prove to be, with a wrong locality label or accidental occurrence; the *Drepanidae* are entirely boreal in America, without any tropical forms. A large, yellow form largely overlaid with brown; inner line of forewing wavy, light, outer line straight from outer third of inner margin to falcate apex; hindwing largely dark, the anal angle broadly pale.

*) HAMPSON, Fauna of British India, Moths vol. 1, p. 347.

4. Genus: **Eudeilinea** Pack.

Distinguished from the preceding genera by the absence of the accessory cell on the forewing, veins 7—10 being stalked. Two species have been described.

E. hermineata Guen. (86 d). All white, wings immaculate; in the form: — **biseriata** Pack. with two series of pale grey spots on each wing. Northeastern North America. Larva on Cornus, between two loosely fastened leaves. It is pale whitish, translucent, the head has a lateral black stripe, faintly crossing the lobes above; anal segment shortly pointed. *hermineata*. *biseriata*.

E. luteifera Dyar differs from the form *biseriata* in the pale luteous colour of the two series of spots on the white wings. Texas. The larva is unknown, but doubtless has the same habits as *hermineata*, of which this may be a racial form. *luteifera*.

10. Family: Mimallonidae.

In arranging this most peculiar family being better known as *Perophoridae*, there is placed before the systematizers a task which is still hardly solvable. If we arrange them at this place in the present work, we do not mean to say that they belong to this proximity phylogenetically, but we merely want to conform to those authors who formerly arranged these insects with the *Drepanidae*, the exterior of the imagines of which is undoubtedly somewhat similar. As to the phylogeny we can only state to-day that the family probably represents a very old type. HAMPSON considered it to be an offspring of the *Limacodidae*, having been developed parallel to the *Megalopygidae* and *Chrysopolomidae*, whilst the *Limacodidae* are said to be descendent from the great Cossid branch. In any case they are a highly specialized group, the ontogenesis and habits of which are entirely homogenous. The resemblance to some Drepanid genera is a purely external feature of convergency merely referring to the shape of the wings and the scheme of markings in the imagines. The latter are well characterized by their medium size, the almost invariable falcate shape of the forewing which in many genera exhibits a most pronounced denticulation of the distal margin. As to the colours and markings, we find almost exclusively dry leaves copied, and yellowish-grey or light brownish colouring frequently with a dark oblique stripe representing a midrib, besides small mildewy spots, often also small hyaline spots.

The developed insect apparently leads a strict nocturnal life and is almost exclusively captured on the lantern. The absence of the proboscis which prevents it from feeding during the imago-stage, also intimates the very old age of the family. The most peculiar feature of the family, however, is the case in which the larva spends its life and which is apparently made of different kinds of material. The young larvae of some *Mimalloninae* as well as *Lacosominae* are known to draw together two small leaves by means of strong silk threads which may be enlarged according to requirement by adding pieces of leaves, if the larva grows larger; these cases are open on both sides and can be quitted by the larva ad lib. When at rest they are freely suspended on a strong thread which, in case the larva wishes to wander, is bitten through. A similar habit we find, for instance, in the species of North-American *Cicinnus* and *Lacosoma*. On the other hand, SEITZ has described cases of tropical species, that are made of quite a different material. I have been able to examine cases of an undefined species, which are made of excrements. The clods of dirt are pressed into a rectangular flat shape like bricks and very regularly placed one next to the other, spun together by means of dense threads and afterwards polished on the outside. Most interesting is the addition of new cases, if the old one is no more sufficient for the grown insect. The case which has almost the shape of a date exhibits ventrally on each open end a shovel-shaped appendage. On the latter the new case is affixed, though on a much larger scale, and in doing so the building material of the original case is also used. Then the larva simply moves into the new house. The larva seems to be very lively and, in case of being alarmed to bite through the thread by which it is suspended, in order to drop on the ground where it is of course difficult to discover among the tangled mass of tropical plants. The larva itself is posteriorly thickened and tapers, towards the end of the head. The pupation takes place in the same case.

HAMPSON's table of the family is incorrect with respect to the absence of the frenulum stated by him as a characteristic of the family; in the *Lacosominae* it is present, though it is often reduced. They are separated from the *Arbelidae* by the distantly separated course of the veins 8 and 9 of the forewing though the *Arbelidae* seem to be very similar in their anatomical structure, and their larvae are wood-borers. Besides, as mentioned above, the proboscis is absent, and on the hindwing vein 8 runs freely or is at most connected by a bar with the anterior edge of the cell, though it only anastomoses with it close to base (M. DRAUDT).

This is a family of Heterocera confined to the New World and Neotropical with the exception of three species which occur in the United States. It can be divided into two subfamilies, the *Mimalloninae*, in which the frenulum is absent, and the *Lacosominae* in which the frenulum is present, often greatly reduced. On fore wing veins 9 and 11 are from the cell, 10 a short spur from 9. On hind wing vein 8 anastomoses with vein 7 at base. The pupal case is of a leathery texture with an opening at each end, and is usually enclosed in leaves and well concealed. (Dr. W. SCHAU).

I. Subfamily: **Mimalloninae** (without frenulum).

I. Antenna pectinated to tips.

A. veins 7 and 8 of fore wing on short stalk

Mimallo.

B. veins 7 and 8 of fore wing well stalked

Cicinnus.

C. vein 6—8 stalked.

1. veins 3 and 4 on fore wing apart.

a. outer margin of fore wing excurved or sinuous

Psychocampa.

b. outer margin of fore wing not excurved or sinuous

Euphaneta.

2. veins 3 and 4 on fore wing stalked

Aleyda.

II. Antenna pectinated, the tips serrate

Roelofa.

1. Genus: **Mimallo** Hbn.

Antenna bipectinate to tip. Palpi obliquely ascending, thickly scaled, the third joint small. Hind tibiae with terminal spurs. Forewing more or less acute and falcate; outer margin usually somewhat excised below apex, crenulate and inbent below vein 3, variability existing in specimens of the same species. Vein 2 from about middle of cell; 3 before angle; 4 from lower angle; 5 from middle of discocellular; 6 from close to upper angle; 7 and 8 on short stalk; 9 and 11 from cell; 10 as a spur from 9. Hindwing: costa convex; termen prolonged at veins 7, 3 and anal angle, crenulate on interspaces; vein 2 slightly beyond middle of cell; 3 before angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 from before end of cell; 8 well upcurved from base of cell.

Type: *M. amilia* Stoll.

amilia.

M. amilia Stoll. (87 a). *Male*: Body and wings light drab grey, frequently suffused with drab, thinly irrorated with black scales. Forewing: a wavy antemedial cinnamon drab line; a large vinaceous brown spot over discocellular and adjoining space, containing two hyaline spots and a light drab grey line within its edge; the fine grey somewhat lunular outer line defined by vinaceous brown narrowly on basal side, but expanding somewhat at costa, the outer edge narrow between veins 4 and 7, dark vinaceous brown, expanding to costa and below vein 4 to inner margin, its outer edge lunular between veins 2 and 4; cilia mostly fuscous. Hindwing: a broad vinaceous patch near base; outer line as on forewing, the dark vinaceous brown space following it very irregular and projecting towards termen between veins 3 and 4. Wings below with outer line lunular between veins, subterminal on hindwing; apex of forewing, spots above tornus, and small terminal spots towards apex of hindwing dark vinaceous brown. *Female*: The termen of wings more even. Expanse, male, 33—52 mm; female, 44—72 mm. From Mexico to Rio de Janeiro.

hector.

M. hector Dogn. (87 a). *Male*: General aspect of *amilia*. Body and wings almost white. Forewing: a fine wavy orange cinnamon antemedial line from a small costal spot and partly interrupted; a double oblique small hyaline spot on outer edge of discocellular; outer line outangled at vein 6, fine, defined on inner side by a fine mikado brown line, followed from vein 6 to costa by a vinaceous cinnamon patch, crenulate on outer edge, and from below vein 5 to inner margin by an army brown space expanding to vein 2, its edge inset below vein 2. Hindwing: a small orange cinnamon spot near base; the line as on fore wing, but from before middle of costa followed by a broad fawn color space, with an irregular outer edge. Wings below with some black irrorations. Forewing: hyaline discal spot partly edged by a double fine cinnamon line; outer line crenulate, present at costa and from vein 3 to inner margin followed by dark vinaceous drab spots. Hindwing: a fine subterminal crenulate line. Expanse 44 mm. Sta. Catharina, Brazil.

brostica.

M. brostica sp. n. *Male*: Body tiller buff, the thorax and dorsum of abdomen on basal half suffused with vinaceous buff. Forewing tiller buff; a few scattered black scales on basal third and termen; termen somewhat suffused with vinaceous buff; a wavy pinkish cinnamon antemedial line, outcurved on costa, vertical from within cell to inner margin; a small hyaline lunule on discocellular; postmedial line fine, outbent on costa, lunular, fuscous, below vein 7 inbent, straight, cinnamon, below vein 4 thicker and lunular, outwardly

edged with cinnamon buff and fuscous lunules between veins 2 and 4 and on inner margin. Hindwing similar, the postmedial line straight from costal to inner margin well above anal angle. Wings below with the postmedial line sayal brown interrupted by veins. Expanse: 43 mm. French Guiana. Type in the National Museum.

2. Genus: **Euphaneta** *nom. nov.* (= *Phaneta* Wkr. *preocc.*)

Antenna bipectinate. Palpi upturned, smoothly scaled, reaching frons. Legs mostly hairy; hind tibiae with short terminal spurs. Body stout reaching well beyond hindwing. Forewing: costa straight, slightly curved terminally; apex somewhat acute; termen oblique, inner margin straight; vein 2 from middle of cell; 3 and 4 from lower angle or slightly apart; 5 from middle of discocellular; 6 shortly stalked with 7 and 8 or from upper angle; 9 and 11 from cell. Hindwing: costa somewhat rounded, the apex and outer margin more so; anal angle faintly acute; vein 2 before lower angle; 5 from middle of discocellular, which is very slightly oblique; 6 and 7 from upper angle; 8 upcurved from near base of cell.

Type: *P. divisa* Wkr.

E. divisa Wkr. (87 a). *Male*: Head buffy brown. Collar pale pinkish buff. Thorax and abdomen light cinnamon *divisa*. drab; tegulae hair brown. Forewing: base to antemedial line with costal edge and cell light buff, space below dresden brown thickly irrorated with black striae, less numerous in cell; antemedial line thick, fuscous, slightly inbent from subcostal to inner margin with a dark line from it, on costa, outcurved near apex; medial and outer space light cinnamon drab becoming darker near termen; a vertical white line on discocellular outwardly dark edged; outer margin narrowly cream white; a terminal prout's brown line, and a similar finer line dividing the pale cilia. Hindwing: base cinnamon brown with some black scales, limited by a fuscous subbasal line; space beyond as on forewing but with a prout's brown large oval patch below cell to near termen; the pale marginal color upbent along inner margin and outer edge of subbasal line; the discal line fuscous, inwardly edged with white and a very fine brown line. Wings below paler without the lines near base; fewer striae at base, more numerous about end of cell, where discal line is preceded by a dark mouse grey shade, also dark shading at apex of forewing. Expanse, male, 40—51 mm; female, 67 mm. French Guiana.

3. Genus: **Psychocampa** *Grt. & Rob.*

Antenna bipectinate, short on terminal third. Palpi short, porrect. Legs mostly hairy; hind tibiae with terminal spurs. Body stout, anal hairs long. Forewing curved near apex which is acute, falcate, outer margin oblique, in some species sinuous; vein 2 from before middle of cell; 6—8 stalked; 9 and 11 from cell. Hindwing triangular, usually with outer margin rounded in those species which have termen of forewing sinuous; vein 2 from beyond middle of cell; 3 before angle; 4 from lower angle; 5 from middle of discocellular; 6 and 7 from upper angle or 7 from before end of cell.

Type: *P. concolor* G. & R.

P. concolor G. & R. (= *cunona* Schs., *stenia* Dyar). (87 a). *Male*: Body and wings sepia. Forewing: trace of *concolor*. a darker antemedial line, inbent from costa, vertical below cell; a fine fuscous annulus at discocellular; outer line fuscous, outbent from costa at 4 mm. from apex, bluntly angled at vein 7 and well inbent to inner margin; a diffuse darker subterminal shade. Hindwing: a fine fuscous medial line and diffuse subterminal shade. Wings below slightly paler; the line on hindwing wavy, postmedial. Female light wood brown, the cilia darker, tipped with light buff. A male from French Guiana is dresden brown. Expanse, male 46—52 mm, female, 45 (type of *cunona*) —62 mm. Para, Brazil; British and French Guiana.

P. ventana Dogn. (87 a). *Male*: Head and collar pinkish cinnamon. Body and wings to line, and on forewing *ventana*. to apex from above vein 7 light vinaceous cinnamon irrorated with a few black scales. Wings: hyaline spots at discocellulars, rather large and almost round; line, fine, black. Forewing: the line very faint at costa, curved or slightly angled at vein 7; costal edge at apex, and termen from below vein 7 kaiser brown. Hindwing: the line fine, medial, touching the hyaline spot. Wings below vinaceous cinnamon, the black irrorations partly forming striae; the line faint, subterminal, slightly wavy; termen narrowly and cilia orange cinnamon, the cilia tipped with white. Expanse: 52—63 mm. Venezuela, Bolivia. The Bolivian specimen larger than those from Venezuela.

P. manicora *sp. nov.* *Male*: Body chestnut brown. Wings to line drab with scattered black scales; *manicora*. termen chestnut brown. Forewing: end of cell to beyond discocellular, scaling below median between veins 2 and 3 and a streak below vein 2 from cell mars orange; a B-shaped hyaline spot at discocellular; line fine chestnut brown, obliquely downbent, bluntly angled below vein 8 and inbent to inner margin followed by a

narrow drab shade expanding to apex and somewhat reddish at inner margin. Hindwing: base light drab; line fine just beyond middle outwardly edged with mars orange suffusions; anal angle acute. Forewing below with inner margin broadly light buff; the mars orange markings as above; the black scales forming disconnected striae; the line faint, subterminal. Hindwing below drab with faint reddish suffusions on disc; the line faint, diffuse, subterminal. Expanse: 54 mm. Manicoré, Amazons. Type in U.S.N. Mus.

belaria. **P. belaria** *sp. n.* (87 a). Head, front of collar, and patches on fore femora burnt sienna; collar behind and thorax deep mouse grey irrorated with black. Abdomen chaetura drab. Wings brownish drab suffused with purplish grey, and irrorated with black; cilia tipped with white. Forewing: an inbent fuscous shade from middle of costa to inner margin, preceded towards inner margin by a faint burnt sienna shade; a quadrate hyaline spot on outer edge of discocellular, cut by vein 5; outer line fuscous, outbent from costa somewhat broken, angled below vein 8, black and inbent, more heavily marked, followed by chestnut shading and a diffuse narrow dark incurved shade limiting the greyer termen. Hindwing: the line postmedial, black, straight, followed by brazil red expanding to anal angle. Wings below brownish mouse grey irrorated with black. Forewing: cell and beyond to line from vein 3 to vein 9 brazil red; line from costa downbent and excurved, less deeply angled. Hindwing below with more numerous black scales; line almost subterminal, irregular. Expanse: 40 mm. Passa Quatro, Minas, Brazil. Type in Berlin Mus.

pluridiscata. **P. pluridiscata** *Dogn.* (87 a). *Male*: Wingshape as in *doralica* and *vitreata*. Head cinnamon buff. Collar cinnamon drab. Body drab irrorated with black. Wings light drab with black scales chiefly at base and along inner margin; the discal spots as in *vitreata*. Forewing: medial line, broad, black; postmedial from a large black costal spot, very faint and outcurved, inbent, well defined, and sinuous to inner margin, followed by a small dark spot above vein 3 and another above vein 1; antemedial space in and below cell congo pink; a small vinaceous pink spot on termen across vein 7. Hindwing largely suffused with vinaceous tawny except at apex; postmedial line black, prominent, sinuous. Wings below largely whitish buff well irrorated with black; the outer line subterminal. Forewing: cell and beyond to line suffused with clay color; a broad black streak below costa from middle of wing to apex; a light coral red terminal space from below vein 7 to vein 4; outer line vertical from costa to vein 4, obsolescent to below vein 3, then inset and straight to inner margin; the line outcurved and sinuous. Expanse: 44 mm. Yahuar Mayo, Peru; Ponte nova, Amazons.

vitreata. **P. vitreata** *Schs.* *Male*: Head pinkish buff. Collar and abdomen pale pinkish buff. Thorax anteriorly white. Wings ecru-drab. Forewing: an antemedial light pinkish cinnamon shade in cell; medial and postmedial lines dark as in *doralica*, the postmedial well outangled from below costal spot; a small pinkish cinnamon shade on termen below apex; no spot between veins 3 and 4, but a small darker shade below vein 2; the hyaline spot B-shaped, with darker scaling on either side. Hindwing: hyaline spot B-shaped on each side of a dark line on discocellular; postmedial line hair brown, wavy from vein 4 to inner margin; termen broadly suffused with light cinnamon drab. Both wings with some black scales and white tips to cilia. Wings below as in *doralica*. Expanse: 40 mm. St. Jean Maroni, French Guiana.

doralica. **P. doralica** *sp. n.* (87 b). *Male*: Head light pinkish cinnamon. Body pinkish buff with a few black scales. Forewing vinaceous buff, from cell to apex tiller buff; termen suffused with vinaceous fawn not reaching apex; some fawn color at base and in cell; a medial fine dark line deeply outangled on costal margin and inbent to inner margin at one-third from base; a B-shaped hyaline spot at discocellular with hair brown shading outwardly; postmedial line from a black spot on costa, very faint beyond cell, forming a lunule between veins 4 and 3 followed by a small hair brown spot, slightly incurved at vein 3 and then vertical. Hindwing vinaceous fawn, the termen broadly fawn color; a broad B-shaped hyaline spot edged on either side with fuscous; a fine, wavy, postmedial line. Both wings with some black scales and white tips to cilia. Wings below partly tiller buff irrorated with more numerous black scales. Forewing: end of median and base of veins from cell carrot red; line more remote outbent and curved, downbent to vein 4, distinct, followed by flesh-ocher from vein 7 to vein 4, below 4 sinuous. Hindwing: the costa and veins pinkish buff. Expanse: 36 mm. Muzo, Colombia. Apex of forewing acute, falcate, the termen sinuous; inner margin of hindwing excurved. Type in U.S.N. Mus.

eminens. **P. eminens** *Dogn.* (87 b). *Male*: Head and abdomen tiller buff. Thorax pale drab grey. Wings pale drab grey irrorated with black; hyaline spots large, B-shaped, irregular and variable on hindwing; the outer line black. Forewing: a medial black shade, inbent, expanding to end of cell and above vein 2, sometimes preceded by light coral red suffusions; outer line irregularly excurved, curved at vein 8 and slightly wavy, followed by cinnamon drab shading and a light coral red spot from veins 6 to 8, sometimes obsolescent. Hindwing: the line medial followed by cinnamon brown or reddish shading, and some similar shading in cell; some diffuse dark subterminal shading. Forewing below without medial shade, the cell except at base, also a streak beyond along veins 6 and 7, and the terminal patch dragon's blood red, sometimes greatly reduced and duller. The line on both wings subterminally fuscous, crenulate, broken by veins. Expanse: 55 mm. Bogota, Guasca, Colombia.

P. beta Schs. (87 b). *Male*: Head, collar and abdomen dorsally pinkish cinnamon; thorax and abdomen *beta*. below drab-white; some scattered black scales on body and wings. Wings to line pale pinkish buff with some black scales; hyaline B-shaped spots edged with fuscous at discocellulars, cilia tipped with white. Forewing: a sinuous inbent antemedial pinkish cinnamon shade; line fine, faint, excurved on costa, angled below vein 8, inbent, fuscous becoming wider to inner margin, followed by some pinkish cinnamon at angle and below the wood brown branch to apex; a triangular white patch, thickly irrorated with black beyond line from vein 3 to inner margin and tornus, this patch outwardly edged by a wood brown shade. Hindwing: line thick, medial, with some orange cinnamon before it below hyaline spot, and beyond it from vein 6, expanding between veins 4 and 2 and with a branch to anal angle; whitish patches irrorated with black at apex and on inner margin above angle. Forewing below: end of cell and beyond suffused with coral red and a similar terminal band from vein 8 to vein 4; inner margin mostly white; line almost obsolescent and outcurved between veins 4 and 3, from vein 3 prominent, sinuous and inbent, followed by the white patch as above. Hindwing below mostly whitish; cinnamon shading around discocellular spot; line subterminal, fine, excurved from vein 3 to anal angle; a brownish shade at apex and at anal angle. Expanse: 39 mm. Type from Costa-Rica and Panama. Specimens from Amazons and French Guiana with the line finer. Specimens from S. E. Brazil ecru drab, the line excurved on costa, more deeply outangled towards apex.

P. sylvia Schs. (87 b). *Male*: Body and wings pinkish buff; anal hairs inwardly fuscous; the line cinna- *sylvia*. mon brown. Forewing: a fine outbent ochraceous buff antemedial line; a narrow oblique, hyaline, B-shaped spot at discocellular outwardly edged by a large van dyke brown spot; line outcurved from costa, inbent below vein 7, followed by a narrow dark shade from vein 7 expanding to termen at vein 8 and costa, and with a fine dark line from it at vein 4 to tornus. Hindwing: the line medial followed by drab suffusions and a fine line from vein 6 to anal angle. A faint hyaline streak at discocellular. Forewing below very similar to upper surface. Hindwing below with discal spot more denuded, outwardly broadly edged with van dyke brown. Expanse: 40 mm. Cayuga, Guatemala.

P. prominens Schs. (87 b). *Male*: Head and collar in front ochraceous salmon; collar behind whitish. *prominens*. Thorax light pinkish cinnamon. Abdomen above orange cinnamon. Forewing drab grey; a hair brown antemedial line, outangled on costa, preceded below cell by a rufous patch, and followed by a similar shade in cell; a whitish grey streak at discocellular; postmedial line fine, hair brown, excurved from a small costal spot, outangled at vein 8 and slightly incurved to inner margin, followed by some rufous and cinnamon brown from vein 5 to vein 8, also between veins 4 and 3 and at tornus; a hair brown subterminal streak from vein 3 to tornus. Hindwing: base narrowly and inner margin whitish; some rufous antemedially and along median to beyond line which is hair brown, medial, followed from costa and vein 4 to termen by drab grey, below vein 4 to termen and anal angle by chestnut brown; a white line on discocellular; cilia of both wings tipped with white. Wings below irrorated with black scales and striae, the white lines on discocellulars prominent; forewing and costal margin of hindwing suffused with hazel and rufous; the line subterminal, hair brown, partly crenulate, termen of forewing from vein 3 to above vein 7 english red; hindwing below costal margin light drab grey. Expanse: 55 mm. Sitio, Tuis, Costa-Rica.

P. lemoulti Schs. (87 b). *Male*: Head and collar ochraceous salmon. Thorax, abdomen and wings light *lemoulti*. pinkish cinnamon, the latter with a few black scales, chiefly on terminal area. Wings: a faint antemedial tawny olive shade; cilia faintly tipped with white. Forewing: a hyaline spot at discocellular cut by vein 5; outer line oblique and excurved from costa, outangled below vein 8 and inbent, straight to inner margin, fine, olive brown, outwardly shaded with mikado brown which extends from angle to apex. Hindwing: the line medial inwardly shaded with pale pinkish buff, outwardly with orange cinnamon, especially along inner margin to termen and on veins. Forewing below pinkish buff, the cell and beyond to line, also on termen from vein 10 to vein 2 zinc orange; line fine hair brown, oblique from costa, angled below vein 8, incurved and approaching termen at vein 3, then faint, inbent, sinuous. Hindwing below pinkish buff irrorated with black; termen narrowly orange cinnamon, expanding broadly at anal angle; a faint postmedial line upcurved from vein 3 to inner margin. Expanse: male, 40—46 mm. A female submitted by Dr. DRAUDT, from Chuchuras, Peru has an expanse of 53 mm. French Guiana; Bolivia; Sta. Catharina, Brazil.

P. mawaja Dogn. (87 b). *Male*: Body and wings light drab, somewhat paler before the line, with a very *mawaja*. few black scales; cilia tipped with white. Forewing: a fine black line on discocellular; outer line obliquely downbent and excurved on costa, black outwardly edged with white to angle below vein 8 where it is followed by a pinkish streak, and from angle the line is inbent, black, becoming wider to inner margin. Hindwing: line postmedial at costa, straight to middle of inner margin, followed by an incurved black shade, narrow at costa expanding to termen at anal angle. Wings below to line whitish grey with a few black irrorations; line on forewing followed by fuscous between veins 4 and 7 to termen, the line otherwise followed by light cinnamon drab not

reaching termen; line on hindwing as above. The venation agrees with *Psychocampa* but the fore wing is simply acute, the outer margin straight, slightly inbent. Expanse: male, 28 mm. Mawajo, Amazons.

bibula. **P. bibula** Dogn. (87 c). *Female*: Body and wings drab, more of a light drab before the line; a faint darker antemedial shade; line fine chestnut brown; cilia pale drab grey tipped with white. Forewing: an obliquely curved hyaline spot at discocellular; line obliquely downbent, slightly rounded below vein 8 and then parallel with termen; apex above vein 8 chestnut brown; termen thickly mottled with white scales. Hindwing: line postmedial, straight; termen as on forewing. Wings below drab grey, with darker terminal suffusions below apices, tornus, and anal angle. Forewing: hyaline spot with a dark streak outwardly. Hindwing: a round fuscous spot at discocellular. Apex of fore wing not acute, the outer margin slightly rounded. The species is allied to *mawaja* Dogn. but can hardly be the female of that species. Expanse: 36 mm. Obidos, Amazons.

4. Genus: **Roelofa** gen. nov.

Male: Antennae bipectinate on basal half, terminal half serrate. Palpi short, porrect. Tibiae hairy, hind tibiae with short terminal spurs. Forewing broad, the apex rounded, termen slightly sinuous; vein 2 from beyond middle of cell; 3 and 4 slightly apart from lower angle; 5 from middle of discocellular; 6—8 stalked; 9 and 11 from cell. Hindwing: costa and termen rounded; vein 2 from near angle; 3 and 4 from lower angle; 5 from middle of discocellular; 6 and 7 from upper angle; 8 upcurved from base of cell.

Type: *R. olivia* Schaus.

olivia. **R. olivia** Schs. (87 c). *Male*: Head hair brown. Collar, thorax and abdomen vinaceous fawn. Wings to line, and on forewing to apex fawn color; terminal space light vinaceous fawn irrorated with small drab scales. Forewing: a round vinaceous buff spot at end of cell; outer line double, the first line chestnut brown, outcurved on costa, almost vertical from vein 8, the second line fuscous outbent along vein 8 to termen, the space between deep vinaceous grey. Hindwing: line as on forewing, postmedial, almost straight from costa to inner margin close to angle. Wings below slightly paler, the discal spot on forewing outwardly edged with chestnut brown. Expanse, male, 48 mm; female, 56 mm. Paramo de Guasca, Colombia. A specimen from the Berlin Museum is labelled *apicistriga* Weym. for which I have no reference.

maricia. **R. maricia** sp. n. (87 c). *Male*: Body pinkish cinnamon; anal tufts fuscous. Wings to line purplish cinnamon buff; line fuscous, outwardly broadly pale vinaceous fawn; termen narrowly purplish cinnamon buff; cilia shortly tipped with pale vinaceous pink. Forewing: a fine darker outcurved antemedial line; an almost round hyaline spot, crossed by discocellular, dark edged, with a projection towards costa containing a few white scales; a slight dark line from costa to outer line which is upcurved to termen above vein 8, below 8 almost vertical to inner margin. Hindwing: the line postmedial, straight to anal angle. Wings below very similar to *olivia* but the line single, and with the hyaline spot in addition. Expanse: 42 mm. Petropolis, Brazil. Type in the Berlin Museum, sent by Dr. HERING for examination.

hegewishi. **R. hegewishi** Drc. (87 c). *Male*: Body vinaceous pink, the anal hairs black. Wings to line pale vinaceous pink, the termen pale cinnamon pink, irrorated with fuscous chiefly on hindwing; the line fine, mikado brown; cilia pinkish cinnamon tipped with black towards apex of forewing. Forewing: a sinuous white line on discocellular edged with avellaneous; line outbent, very faint on costa, angled on vein 8, the space between veins 8 and 10 hair brown to apex, below vein 8 the line is slightly inbent, from below vein 6 outwardly edged by a white line and then by a line of denser fuscous scaling. Hindwing: line as on forewing postmedial to anal angle. Wings below pale ochraceous buff with small dark irrorations. Forewing: light pinkish cinnamon outwardly edged with fine black scales. Hindwing: the line only visible in transparency and preceded by a faint pinkish buff line. Expanse, male, 36 mm; female, 45 mm. Jalapa, Mexico. The type, a female, is in the Berlin Museum. The characters agree with *olivia*, but the apex of forewing is bluntly produced.

narga. **R. narga** Schs. (= *maera* Schs.) (87 c). *Male*: Head and thorax brownish drab. Abdomen light vinaceous drab dorsally suffused with flesh-ocher; anal hairs black. Forewing to line brownish drab with a few black scales; a round whitish spot irrorated with rufous at end of cell, darker edged, a small similar spot at cell between veins 2 and 3, and a still smaller white spot between veins 4 and 5 at cell; line dark vinaceous brown continuing from angle to termen above vein 8, the line fainter on costa where outbent and excurved to angle with a small pale shade above it; space beyond line white, terminally suffused with apricot buff with a series of small triangular black spots on veins just beyond line. Hindwing slightly paler, the costa light buff; a fine dark point on discocellular, line postmedial; termen as on forewing. Wings below paler with the same general pattern. Expanse, male, 39 mm. French Guiana; Joinville, Brazil; Ponte Nova, Amazons.

5. Genus: **Aleyda** *gen. nov.*

Male: Antenna bipectinate to tip. Palpi ascending, reaching frons, smoothly scaled. Legs hairy; hind tibiae with terminal spurs. Forewing: costal margin nearly twice as long as inner margin, convex towards apex which is rounded, the outer margin inbent; cell short; vein 2 from beyond middle of cell; 3 and 4 stalked; 5 from middle of discocellular; 6, 7, 8 stalked; 9 and 11 from cell; 10 stalked on 9. Hindwing: costa convex; outer margin slightly rounded; veins 2, 3, 4 stalked; 5 from middle of discocellular; 6 and 7 from upper angle; 8 upcurved from base of cell.

Type: *A. accipiter* Dogn.

A. accipiter Dogn. *Male*: Forewing with apex less acute and less inbent. Hindwing with termen slightly rounded with anal angle hardly produced and not acute; cell of forewing short and incurved, of hindwing shorter at vein 7 than at median. Head and thorax light greyish vinaceous. Abdomen vinaceous brown. Wings mostly dark vinaceous brown with scattered black scales; hyaline lines on discocellulars. Forewing: apical third of wing vinaceous fawn; an antemedial outcurved black line; outer line remote, fine and indistinct, dark vinaceous brown, excurved from costa, angled below vein 8 with a projecting shade to apex, below vein 3 black, incurved below vein 2; base of cilia and termen narrowly, from middle of inner margin, english red. Hindwing: a round zinc orange spot on inner margin near base, edged with black; cilia and termen narrowly as on forewing. Wings below paler; the line on forewing heavily marked below vein 2; a medial black irregular line on hindwing. Expanse: 30 mm. Lino, Panama.

6. Genus: **Cicinnus** *Blanch.*

(= *Perophora* Harr., preocc., *Saccophora* Harr., preocc.)

Male: Antenna bipectinate to tip. Palpi ascending, thickly scaled, smooth, third joint small. Forewing: apex produced, more or less acute; outer margin sinuous or almost straight, inbent; inner margin straight, vein 2 from middle of cell; 3 near lower angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 stalked; 9 and 11 from cell. Hindwing: costa somewhat convex; outer margin rounded; vein 2 from beyond middle of cell; 3 close to angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 from before angle.

Type: *C. orthane* Blanch.

Group 1.

Species with hyaline B-shaped spot on forewing, and a hyaline spot on hindwing except *packardi*.

The first three species: *packardi*, *fogia* and *motagus* show variability, veins 6—8, or veins 7 and 8 being stalked.

C. packardi Grt. (87 c). *Male*: Body and wings to line tilleul buff, sometimes almost white, irrorated with black scales; avellaneous suffusions on front of collar and on abdomen; cilia tipped with white. Forewing: an almost medial curved and inbent avellaneous shade; a hyaline B-shaped spot at discocellular; outer line remote, excurved from costa and acutely angled between veins 7 and 8 near apex, fine, fuscous and inbent to inner margin at two-thirds from base, followed by a sayal brown shade, the terminal space otherwise pale drab grey. Hindwing: the fuscous line medial followed by broader sayal brown shading, the termen as on forewing. Wings below more thickly irrorated with black; forewing suffused with pale tawny olive, the line faint, outcurved and sinuous; hindwing with a faint dark streak on discocellular, the line subterminal, outcurved between veins 4 and 2. Expanse: male, 38—43 mm; female, 49 mm. Cuba.

C. fogia Schs. (87 c). *Male*: Head fawn color. Collar drab. Thorax whitish. Abdomen above cinnamon, underneath pale drab grey. Wings to outer line whitish or pale ecru drab with only a few scattered black scales; curved hyaline spots on discocellulars cut by vein 5, edged with brown and a few red scales. Forewing: a faint darker antemedial line and a small dark medial spot on costa; outer line from a fuscous point on costa, curved and outbent across vein 8, angled subterminally then consisting of a double fuscous line filled in with pale drab grey and closely followed by a narrow dresden brown shade with a similar diverging shade from vein 4 to tornus; the outer part of double line extends to apex and a fuscous costal shade which reaches apex; subterminal flesh-ocher shade from above vein 5 to above vein 7. Hindwing: a brownish antemedial shade; the postmedial line double, fuscous, close to end of cell; outer area olivaceous drab, the termen narrowly pale drab grey, the cilia tipped with white. Forewing below largely suffused with drab, irrorated with dark scales and striae; a whitish oblique patch below middle of outer margin; a coral red shade at end of cell and base of veins 3 and 4; the subterminal mark above vein 5 coral red; the line faint, outcurved and sinuous. Hindwing below greyish white irrorated with black scales; the line more remote, irregular and broken; a buffy brown patch at anal angle; some reddish scaling at hyaline spot. Expanse: male, 46 mm; female, 63 mm. French Guiana; Ponte Nova, Amazons. Forewing acute and subfalcate.

- motagus.* **C. motagus** Schs. (87 d). *Male*: Body pale drab grey, the head, collar and abdomen dorsally suffused with pinkish buff. Wings pale drab grey with some black irrorations; hyaline B-shaped spots on discocellulars; on forewing larger edged with cinnamon brown and red; cilia tipped with white. Forewing: a faint outcurved pinkish buff antemedial shade; outer line benzo brown, wavily oblique, outbent along vein 8 to near termen with a fuscous shade from it to apex, below vein 8 well inbent to inner margin, followed by a diffuse buffy brown shade and a similar vertical line from vein 3 to inner margin; some red scaling at end of median vein. Hindwing: the line medial followed by buffy brown shading gradually expanding to inner margin, containing some red scaling at lower angle of cell. Wings below pale drab grey irrorated with black, the lines faint; forewing with cell and beyond to line suffused with cinnamon drab; some reddish scaling below cell and terminally from vein 8 to below vein 5; hindwing with line postmedial, upcurved from vein 3 to inner margin; some red on veins at cell. Expanse: 40 mm. Quirigua, Cayuga on the Montagua River, Guatemala.
- corallina.* **C. corallina** Dogn. (87 d). *Male*: Almost the same as *xingua*. The apex of forewing more acute. The hindwing with the line more remote from base; a hyaline streak at discocellular; the line on underside evenly curved, partly lunular. Expanse: 36 mm. Pacho, Colombia; São Paulo de Olivença, Amazons, French Guiana; Panama.
- corcovada.* **C. corcovada** Schs. (87 d). *Female*: Head, collar, thorax and wings light vinaceous fawn with very few scattered black scales; abdomen dorsally fawn color. Forewing: a buffy brown medial shade slightly inbent; a narrow hyaline spot at discocellular; outer line remote, faint on costa, outbent and bluntly angled, then fine, fuscous, followed by an ochraceous tawny diffuse line, and a similar vertical shade from vein 4 to tornus; on costa the line is preceded by a short oblique brownish shade. Hindwing: an antemedial ochraceous shade and a broad similar shade beyond the fuscous medial line, which touches the lower end of a hyaline line on discocellular. Wings below light buffish drab with numerous dark striae and scales. Forewing: some light coral red suffusions below and beyond cell; termen coral red from below vein 8 to near vein 3; the line buffy brown, lunular from below vein 4. Hindwing: the line almost subterminal, outcurved and lunular. Expanse: 43 mm. Rio de Janeiro, Brazil.
- thermesia.* **C. thermesia** Jones. *Male*: Head and collar mostly reddish brown. Thorax light brown suffused with lilacine. Forewing lilacine irrorated with white scales tipped with black; costa light brown, darker towards apex; a very wavy antemedial line followed by light brown suffusions; outer line dark brown, excurved on costa, abruptly angled below vein 8, then inbent followed by narrow lilacine and a brown suffusion confluent with a dark subterminal shade from discal fold to tornus; a red suffusion beyond line below apex; two square brown spots on costa at one and two-thirds; termen dark brown; cilia tipped with lilacine; a minute hyaline spot at discocellular. Hindwing deeply suffused with reddish brown, veins on outer half suffused with red; the dark medial line outcurved from costa to vein 2 then straight to inner margin; a minute hyaline spot at end of cell; a diffuse dark subterminal shade. Wings below very much as in *C. corcovada* Schs. of which it may be the male. Expanse: 41 mm. Alto da Serra, Santos. Not in the National Museum. The apex rounded in figure published.
- fenestrata.* **C. fenestrata** Jones. The species is only known to me from description and a figure received from Mr. Jones. *Male*: Body and wings light brown with black irrorations and suffused with light vinaceous cinnamon. Forewing: a diffuse, indistinct, double, dark medial shade from costa across end of cell to inner margin; trace of postmedial dark shade with diffuse spot above vein 8; a dark discocellular bar followed by minute hyaline spots above and below vein 5; a small pink subterminal suffusion between veins 6 and 8; cilia dark brown. Hindwing like forewing, but shade is postmedial, forming a single line from vein 2 to inner margin; discocellular bar and hyaline spots larger. Forewing below light brown suffused with pink and irrorated with black; veins, cell, and subapical patch heavily suffused with red; a narrow, dark, diffuse postmedial shade; a dark discocellular bar. Hindwing below with red suffusions on veins only; dark postmedial shade and discocellular bar. Expanse: 46 mm. Castro, Parana.
- malca.* **C. malca** Schs. (87 d). *Male*: Body above pale vinaceous buff thickly irrorated with black, the abdomen dorsally suffused with prout's brown. Forewing drab grey irrorated with black scales partly forming striae; a faint hair brown antemedial line; some light coral red scaling below median at end of cell and on base of veins 3, 4 and 6; an oblique hyaline streak on discocellular; outer line at costa broad, diffuse, smoky fuscous, from vein 8 to inner margin fine, fuscous; a vertical prout's brown thick line from vein 7 to tornus, the termen pale drab grey partly suffused with light ochraceous buff. Hindwing largely suffused with cinnamon brown, and irrorated with black; hyaline streak at discocellular; the line fine, fuscous, medial; a subterminal prout's brown line from apex to anal angle; termen narrowly pale drab grey; cilia mostly white. Wings below partly pale drab grey, chiefly on termen with scattered black scales; base to line largely suffused with cinnamon drab. Forewing: the coral red scaling at veins more intense, and similar coloring sub-

terminally from vein 8 to near vein 3, the termen narrowly and base of cilia prout's brown; the line faint and mostly crenulate. Hindwing: the line postmedial, crenulate toward inner margin; termen as on forewing. Expanse: 41 mm. French Guiana.

C. submarcata Schs. (87 d). *Male*: Frons drab. Body light drab, anal hairs partly fuscous. Wings *submarcata*. to outer line light drab, beyond line drab; discocellular spots hyaline, B-shaped edged with cinnamon brown; a few scattered black scales; outer line fine, cinnamon brown; cilia tipped with white. Forewing: an antemedial cinnamon drab line deeply outangled on costa, slightly outbent from subcostal to inner margin; outer line excurved on costa, double, heavier on basal side, filled in with white, bluntly angled below vein 8 and inbent to inner margin, the outer of the two lines finer, pale fawn color, and a similar fine subterminal shade from vein 4 to tornus; an upcurved dark line from angle to termen at vein 8. Hindwing: the line medial touching hyaline spot; a postmedial and a terminal pale fawn colour shade. Forewing below: costal edge dark olive buff; cell and a shade towards apex drab grey; space below cell to outer line and tornus cinnamon drab; termen from vein 8 below curved line cream white narrowing to a point at vein 2; outer line fine, crenulate from vein 4 to inner margin. Hindwing below light drab, the veins light cinnamon drab; a faint postmedial line crenulate towards inner margin; some black irrorations on both wings. Expanse: 38 mm. French Guiana.

Group 2.

Species with a hyaline spot on forewing only.

C. externa Moore (87 d). *Male*: Head, collar and abdomen light pinkish cinnamon. Thorax fawn colour, *externa*, all with a faint olivaceous tinge. Wings to line light pinkish cinnamon with a few scattered black scales; cilia citrine drab tipped with white. Forewing: an outcurved darker medial shade followed by a small snuff brown spot on costa; a hyaline spot on outer edge of discocellular cut by vein 5; outer line remote, fine, black, outwardly shaded with buckthorn brown, outangled close to apex; terminal space partly light pinkish cinnamon with a vertical buckthorn shade from vein 5 to tornus. Hindwing: the line fuscous black, medial; outer half cinnamon brown, becoming paler towards costa. Wings below light ochraceous buff irrorated with black scales and striae; cilia cinnamon brown tipped with white. Forewing: median vein, base of veins 3 and 4, also base of veins 6 and 7 light coral red; termen from vein 7 to vein 2 coral red; the line not angled but curved, from vein 4 to inner margin crenulate. Hindwing with the line subterminal, faint, curved and crenulate. Expanse: 48 mm. Rio de Janeiro; Castro, Parana.

C. musa Schs. (87 d). *Male*: Body drab grey, the front of collar and abdomen dorsally except at base *musa*, suffused with orange cinnamon. Forewing: base to beyond cell on costa and to middle of inner margin light cinnamon drab, then pale drab grey to outer line and apex; a small B-shaped hyaline spot at discocellular; outer line fine, benzo brown, outangled between veins 7 and 8 with a fine reddish line beyond it from vein 5 to termen below apex; terminal space light drab; costal edge coral red. Hindwing: base pale drab grey to medial dark line; terminal space light drab with mikado brown shading along the line; cilia of both wings darker tipped with white; black irrorations scattered over the thorax and wings. Underside of wings partly suffused with ochraceous tawny, irrorated with black; line of forewing outcurved below costa, on hindwing postmedial and faintly crenulate; a dark discal spot on hindwing. Expanse: male, 40 mm; female, 50 mm. Castro, Parana.

C. cordubensis Berg (= *schulzi* Weyenb., *nigrescens* Schaus) (87 e). *Male*: Head and collar light cinnamon drab. Thorax drab. Abdomen whitish suffused with light drab with some scattered black scales. Wings bone white irrorated with black, less so on terminal space; cilia vinaceous buff tipped with white. Forewing: base suffused with avellaneous extending along inner margin; a thick fuscous antemedial line inbent from costa to inner margin; space between lines sometimes fuscous; a hyaline B-shaped spot on discocellular; postmedial line fuscous angled at vein 6 with a vinaceous buff line from angle to apex. Hindwing: the line medial, outcurved; brownish suffusions along inner margin. Forewing below with postmedial line outcurved. Hindwing below with line postmedial and curved. Expanse: 40—44 mm. Argentina; Castro, Parana.

C. felderia sp. nov. (87 e). *Male*: Very similar to *despecta*. Larger and can always be recognized by *felderia*, the outer line of the forewing which is more deeply outangled, starting from costa at a greater distance from apex, and is followed beyond angle between veins 7 and 8 by a light coral red line; the apex is rather more prolonged and more acute. The genitalia also differ. Expanse: male, 45—50 mm; female, 57 mm. Several localities in Western Mexico; San Salvador.

C. despecta Wkr. (= *curtisea* Weyenb., *sanguinolenta* Fldr.) (87 e). *Male*: Body light drab; head *despecta*, partly or entirely light coral red; collar in front and abdomen dorsally suffused with pinkish cinnamon. Wings whitish or pale drab grey irrorated with black chiefly on basal half. Forewing: a faint light cinnamon drab medial shade; a hyaline B-shaped spot at discocellular partly edged with black; outer line remote, from a cinnamon spot on costa fuscous black, outbent and angled close below vein 8, then inbent, followed by a sayal

brown line, at angle a black line extends to apex; a faint light cinnamon drab suffusion on terminal space from vein 3 to tornus; costal edge sayal brown. Hindwing: line medial, fuscous black followed by a russet shade except at costa. Wings below varying from light drab to light buff more thickly irrorated with black scales and striae, the forewing with the line faint, hardly angled, followed by a russet shade to termen between veins 4 and 7, the hindwing with a faint sinuous postmedial line, and usually a small dark spot on discocellular. Expanse: male, 34—46 mm; female, 50 mm. Argentina; Southern Brazil. The figure of *curtisea* Weyenb. in Tijdschrift is very poor.

xingua. **C. xingua** Dogn. (87 e). *Male*: Body and wings vinaceous buff irrorated with black. Forewing: an antemedial, almost medial clay color shade from a dark point on costa; an oblique hyaline spot at discocellular finely edged with black; the outer line fine, hair brown, oblique from costa, angled below vein 7 and inbent; followed by a sayal brown shade, oblique, from vein 5 to tornus. Hindwing: a small dark spot on discocellular; line fine, medial; termen largely suffused with sayal brown darkest subterminally. Forewing below suffused with ochraceous salmon becoming ochraceous orange at termen below apex to vein 4; the line broader towards costa, outcurved and sinuous. Hindwing below: a black line on discocellular, the postmedial line almost vertical to vein 4, then inbent to inner margin. Expanse: 32 mm. Ponte Nova, Rio Xingú, Amazons; Callao, Peru; Argentina. A small species with apex of forewing less acute.

pulverula. **C. pulverula** Schs. *Female*: Body and wings pale ecru drab well irrorated with black scales, abdomen below with a black ventral line. Forewing faintly suffused with light cinnamon buff to postmedial line; lines sayal brown, the antemedial inbent on costa, then lunular, almost vertical, the postmedial outcurved beyond cell, crenulate. A B-shaped hyaline spot at discocellular edged with snuff brown. Hindwing: a subbasal curved line; outer line outcurved beyond cell, crenulate and dentate. Cilia of both wings pale sayal brown tipped with white. Wings below very similar to upper surface with only the outer line, which is vertical on costa of forewing to vein 8, then outcurved, and on hindwing is nearer termen. Expanse: 54 mm. São Paulo, Brazil.

forbesi. **C. forbesi** sp. nov. (87 e). *Male*: Body ochraceous buff, the abdomen with sayal brown segmental lines, the anal tufts chestnut brown. Wings ochraceous buff irrorated with apricot buff to outer line; the lines apricot buff, outwardly pinkish; termen narrowly apricot buff, the cilia tipped with pinkish buff. Forewing: a fine, sinuous, outbent, antemedial line; an oblique hyaline spot at discocellular, divided by vein 5, outwardly with some fuscous scaling; outer line outbent and angled close below vein 7, followed by black scaling continued from angle to apex, and with a branch line from vein 4 to tornus; an apricot buff line below median and vein 2 to termen; the veins beyond line apricot buff; smoky drab suffusions irrorated with brownish scales on interspaces beyond cell to line. Hindwing: the line from costa near apex to middle of inner margin; a fine line from vein 6 near postmedial to termen at vein 2. Wings below warm buff with numerous fuscous scales. Forewing: no antemedial line; a black patch from outer line above vein 3 to tornus. Hindwing: the line finer, slightly curved; a white and fuscous spot at discocellular. Expanse: male, 37 mm; female, 50 mm. French Guiana. Type in Cornell University Collection. The apex of forewing somewhat falcate, the termen sinuous. Named in honor of Dr. W. T. M. FORBES.

eugenia. **C. eugenia** Schs. *Male*: Body and wings light greyish olive; cilia darker tipped with white; line clay colour outwardly edged with light ochraceous buff. Forewing: an oblique hyaline B-shaped spot, edged with clay colour, at discocellular; outer line light ochraceous buff on costa, almost imperceptible, outbent, angled at vein 7, inbent, straight followed by a darker greyish olive shade above inner margin to tornus. Hindwing: the line medial, straight. Wings below darker, duller, the shade above inner margin at tornus of forewing benzo brown, the hindwing darker on terminal half and a dark point on discocellular. Expanse: 37 mm. French Guiana; São Paulo de Olivença, Amazons.

volucris. **P. volucris** Schs. (87 e). *Male*: Forewing acute, falcate, termen oblique. Hindwing with anal angle produced to a point. Body and forewing cinnamon drab, the line verona brown. Forewing: a very oblique hyaline spot medially constricted; the line outangled at vein 7 followed below 7 by a finer fuscous parallel line, and a fine fuscous shade from vein 3 to tornus; from angle of line a verona brown line and shade to apex; terminal space light cinnamon drab irrorated with minute verona brown scales. Hindwing light cinnamon drab; line postmedial downbent close to inner margin, closely followed by a finer dark line; termen with fine irrorations as on forewing. Wings below similar, the hindwing with a fine denuded lunule and verona brown spot at discocellular. Expanse: 37 mm. Sixola River, Costa Rica.

gentilis. **C. gentilis** Schs. (87 e). *Male*: Forewing: apex produced, outer margin sinuous. Body and wings light buffish drab irrorated with drab scales. Forewing: a fine antemedial line; an oblique hyaline spot at discocellular edged with fuscous, more broadly on outer edge; outer line narrow, cinnamon drab, oblique from costa, angled below vein 7 near termen and inbent to inner margin; a fine fuscous line from vein 4 to tornus; a

dark terminal line from vein 8 to vein 3; cilia tipped with silky wood brown. Hindwing: line postmedial on costa to middle of inner margin; a fine line from costa near postmedial to anal angle; cilia as on forewing. Hindwing below with the line postmedial, angled at vein 4, not followed by the fine line. Female greyer, with the markings very fine. Expanse: male, 24 mm; female, 32 mm. Sixola River, Costa Rica; French Guiana; Amatura, Amazons.

C. dulcis Schs. (87 e). *Male*: Body ochraceous buff, the anal hairs in type sayal brown. Forewing brownish vinaceous cinnamon to line, beyond line olivaceous cinnamon; a faint dark line outangled at middle of costa, inbent along subcostal, then as an antemedial line slightly outangled below vein 2 which rises before middle of cell; a pale vinaceous pink space between the lines from vein 2 to inner margin, and a large similar space at apex; a B-shaped oblique hyaline spot at discocellular outwardly edged with fuscous; the outer line obliquely excurved from costa, hair brown, acutely angled at vein 7, then inbent, sayal brown inwardly edged with pale orange to vein 2 and below it with whitish; some pale vinaceous pink beyond line on inner margin and traces of a dark shade from line at vein 4 to tornus. Hindwing: base to line pale vinaceous pink; line as on forewing, medial to well below middle of inner margin; outer space olivaceous cinnamon; some pale vinaceous pink on inner margin below line, and at apex. Wings below paler, the outer line on forewing outcurved, on hindwing postmedial, sinuous. Some black scaling above and below on both wings. Expanse: 47 mm. Juan Viñas, Costa Rica. The forewing is broad, the apex acute but not produced.

C. olasis sp. nov. *Male*: Body and wings light pinkish cinnamon with a few fuscous scales. Wings above: outer line fine, olive brown inwardly edged with yellow white; cilia orange cinnamon at base followed by a dark shade and white tips. Forewing: faint traces of an antemedial line; hyaline spot oblique B-shaped edged with black; line as in *dulcis*. Hindwing: the line medial to middle of inner margin. Wings below paler, pinker, the termen suffused with brownish cinnamon, the line very faint. Expanse: 39 mm. Central America. Wing shape as in *dulcis*.

C. roscida Dogn. *Female*: Body and wings to line pinkish buff with a few black scales. Wings: an antemedial outcurved broad pinkish cinnamon shade; terminal space cinnamon, slightly paler along outer margin; cilia light greyish olive, paler on tips. Forewing: outer line broad on costa, oblique, brownish cinnamon, close below 8 as a fine line outbent, angled and inbent chestnut brown, with a brownish cinnamon line along vein 8 to termen; an oblique hyaline spot at discocellular. Hindwing: the line as on forewing, medial. Wings below pinkish buff with dark striae and black scales. Forewing: cell and beyond to near line and above vein 2, also termen from vein 8 to vein 3 rufous; line wood brown, postmedial, outcurved, below vein 4 faint, inbent, crenulate. Hindwing: line faint, subterminal, outcurved and crenulate. Expanse: 46 mm. São Paulo, Brazil.

Group 3.

The following species have a black line or spot on discocellular of forewing.

C. chabaudi Dyar (87 f). *Male*: Head and collar light ochraceous salmon or tawny, the collar tipped with white. Thorax and abdomen greyish changing to sayal brown according to light, irrorated with large black scales. Wings light buffish grey irrorated with large black scales and some black striae except on termen; cilia brownish olive tipped with white. Forewing: a fuscous shade from middle of costa inbent to inner margin, very faint in type; outer line usually fuscous, outangled above vein 7, fainter and paler in type; a silvery white spot at discocellular inwardly edged by a fine dark line; outer line followed by irrorations on brownish suffusions, not reaching termen except at apex. Hindwing: costa paler; postmedial line slightly outcurved; inner margin half suffused with mikado brown to beyond postmedial. Wings below paler with fuscous striae; fuscous lines on discocellulars, the forewing with outer line well outcurved to vein 3, then incurved, the hindwing with line subterminal, upcurved from vein 3 to inner margin, almost obsolete in type. Expanse: 53 mm. Zacualpan, Mexico.

C. mexicana Drc. (87 f). *Male*: Body and wings pale vinaceous fawn, the head, collar, base of forewing and inner margin of hindwing suffused with light pinkish cinnamon, all with scattered black scales. Forewings: a black line on discocellular followed by a whitish spot; a faint darker antemedial fine wavy shade; postmedial line fine, black, outangled above vein 6; a faint reddish streak from angle of line. Hindwing: a fine black line on discocellular; a fine black medial line. Forewing below with black discal line and silvery white spot; reddish suffusions except on costa and inner margin. Expanse: male, 45 mm; female, 60 mm. Orizaba, Jalapa, Mexico.

C. tuisana Schs. (87 f). *Male*: Head vinaceous cinnamon; collar and abdomen above pinkish buff, the thorax whitish grey, all with scattered black scales; abdomen below whitish grey irrorated with black. Wings lilacine grey thinly irrorated with black. Forewing: a small round deep mouse grey spot at end of cell; a faint antemedial darker shade; postmedial line fine, faint, outbent on costa, angled between veins 7 and 8 and inbent to inner margin, followed by a cinnamon shade especially at veins 3—4, and at vein 1 to fold; a peach red streak across vein 6 beyond line; apex slightly darker. Hindwing: a small black spot at end

of cell; a fine, eurved, black medial line followed by a broad cinnamon shade with more numerous black scales; termen darker grey. Wings below more thickly irrorated with black scales and striae; black discal points. Forewing: disk and cell suffused with cinnamon; lines below usually faint; a peach red patch on termen from vein 3 to above vein 7; line on hindwing below subterminal, wavy. Expanse: male, 48 mm; female, 57 mm. Costa Rica. Guatemala; Amazons.

acuta. **C. acuta** Schs. (87 f). *Male*: Body above and wings drab grey with a faint brownish tinge, irrorated with black. Wings: the line buffy brown followed by a slight white shade; small black spots on discocellulars; cilia darker shortly tipped with white. Forewing: the line postmedial, oblique from costa, angled close below vein 8 and inbent. Hindwing: the line postmedial passing close to discal spot. Wings below tiller buff, the forewing largely suffused with wood brown, except at apex and on inner margin; the line faint, outeurved, sinuous; hindwing with the line almost subterminal, faint, outeurved and sinuous. Expanse: male, 32—42 mm; female, 52 mm. Petropolis, Brazil; Amazons; Costa Rica; Guatemala. Forewing with apex produced, outer margin sinuous.

pudens. **C. pudens** Schs. (87 f). *Male*: Body and wings drab thinly irrorated with black. Forewing: lines fine, darker; antemedial line outangled on costa, vertical from subeostal to inner margin; a small fuscous black spot on discocellular; outer line broad and fuscous on costa, outangled above vein 6, fine, double, parallel with termen to inner margin; a fuscous shade on costa from line to apex, and a similar subterminal shade from vein 4 to tornus. Hindwing: a fine outer line, wavy from below vein 4; termen suffused with fuscous. Forewing below with costa at apex greyish, also subterminal shadings below vein 4, and at discal spot. Hindwing with greyish suffusions especially on termen; a blackish shade on termen before anal angle; the outer line nearer termen and more distinct. Expanse: male, 45 mm; female, 50 mm. Sixola, Juan Vinas, Costa Rica; Paeho, Columbia. Some specimens have a reddish patch on underside of forewing from veins 5—7 on termen.

solvens. **C. solvens** Dyar. *Male*: Similar to *pudens* but without the fuscous shade on costa at apex or on termen. Hindwing with a very slight darker shade on termen before anal angle. Underside of fore wing with a capueine yellow patch on termen between veins 5 and 7, the postmedial line inbent at vein 3. The female is light ochraceous buff irrorated with black. Forewing: antemedial line faintly darker, sinuous; postmedial line mouse gray, macular from below angle above vein 6, followed by a brownish parallel shade from vein 5 to inner margin. Hindwing: a fine dark streak on discocellular; a medial curved line the continuation of postmedial line on forewing. Wings below paler. Forewing: postmedial line inbent above vein 3. Hindwing below with the line subterminal, excurved below vein 3 to inner margin. Expanse: male, 44 mm; female, 50 mm. Cabima and La Chorrera, Panama.

incerta. **C. incerta** Mschlr. (87 f). *Female*: Body drab. Wings drab grey mottled with drab, the terminal space drab. Forewing: base suffused with drab, limited by a wavy hair brown thick line, outeurved on costa inbent from subeostal to median, then vertical; a small dark spot on discocellular; outer line finer, hair brown exeurved and outbent on costa, slightly inbent from below vein 8, followed by benzo brown shading, expanding at apex and between veins 3 and 5. Hindwing: a dark line on discocellular; postmedial line bluntly eurved, hair brown, followed by benzo brown shadings as on forewing. Wings below light drab irrorated with black. Forewing: an outer hair brown line outeurved to vein 3, then incurved to inner margin; a light vinaceous cinnamon patch beyond line from vein 4 to vein 7. Hindwing: a subterminal dark line parallel with termen from costa to vein 3, then exeurved. Expanse: 41 mm. Surinam. Described from the type specimen kindly sent to me for examination by Dr. HERING of the Berlin Museum.

orthane. **C. orthane** Blanch. *Female*: Body light ochraceous buff somewhat suffused with drab grey. Wings light ochraceous buff with transverse black striae. Forewing: an irregular black antemedial line, outangled on costa and inbent; a dark line on discocellular and a short parallel line beyond; outer line exeurved and outbent, at vein 7 inbent, lunular, black, outwardly paler edged defined by dark suffusions on termen. Hindwing: a black point on discocellular, with faint line from it to inner margin; a curved postmedial line; traces of a subterminal line formed by the black striae. Expanse: 62 mm. Chile. The description is made from the figure in Gay's *Historia de Chile*. The figure shows vein 5 on forewing from lower angle of cell, evidently an error in drawing.

latris. **C. latris** Schs. (87 g). *Male*: Head and palpi zine orange. Collar pinkish cinnamon. Body and wings pinkish buff with scattered black scales. Forewing: basal third suffused with pinkish cinnamon; antemedial line dark, very faint, outeurved; a small black spot on discocellular; outer line fine, blackish from a small blackspot on costa, outeurved and inbent to inner margin at two thirds from base, closely followed by a cinnamon line; costa from line to apex suffused with mouse grey; faint brown shade on termen from line at vein 4 to tornus. Hindwing: a curved black medial line; a fine dark line on discocellular; outer half of wing suffused with mikado brown. Forewing below suffused with light coral red except on costa and inner margin, a terminal patch of coral red from vein 3 to vein 8; black striae over greater part of wing. Hindwing below

with black striae and scales forming a vague medial shade and irregular outer line. Expanse, male type 54 mm. The female has the outer half of hindwing much paler and with only a faint reddish terminal patch on forewing. Expanse: female, 63 mm. Tuis, Juan Viñas, Costa Rica. Other specimens from Guatemala which I can hardly separate measure 36 mm and have the apex less acute. From Venadio, Mexico we have small specimens, but much paler.

C. narseres *sp. nov.* *Male*: Body and wings cinnamon buff; a few black scales on base of abdomen. Wings shorter and broader than in *marona*; the lines fine, tawny olive. Forewing: antemedial line barely traceable; discal spot small, black; outer line more remote from apex, slightly excurved on costa; a few black scattered scales. Hindwing: the line medial; a few black scales at base and beyond line. Expanse: 45—50 mm. Rio Songo, Bolivia. Type in the U. S. National Museum.

C. melsheimeri *Harris* (= *egenaria* *Wkr.*) (87 g). *Male*: Body and wings pale cinnamon pink varying to drab grey, irrorated with hair brown scales, the wings sometimes suffused partly with roseate. Wings: the lines very fine or more heavily marked, fuscous, especially in Mexican specimens. Forewing with an antemedial inbent line, frequently obsolete; postmedial line outangled between veins 7 and 8; a fuscous streak on discocellular; cilia tawny olive tipped with white. Hindwing with the line just beyond middle. Forewing below with basal half partly orange rufous or light vinaceous cinnamon; the postmedial line outcurved to vein 3, then incurved. Hindwing below with the line remote, vertical from costa, angled and inbent from vein 3. Expanse: male, 33—45 mm; female, 43—46 mm. United States to Hidalgo, Mexico.

C. bilinea *Schs.* *Male*: Head and collar avellaneous; body pale ochraceous buff, with a few scattered dark scales, the anal hairs natal brown and fuscous. Wings pale ochraceous buff with wood brown irrorations; cilia fuscous partly tipped with white. Forewing: a fine buffy brown antemedial line slightly inbent; a similar postmedial line slightly outcurved; a faint darker line on discocellular; termen narrowly ochraceous salmon. Hindwing with a fine medial line. Forewing below with no antemedial line. Hindwing below with the line postmedial and slightly outcurved. Expanse: male, 31 mm; female, 40 mm. Castro, Parana.

C. primolus *sp. nov.* (87 g). *Female*: Body and wings pale pinkish buff irrorated with fuscous; collar light pinkish cinnamon. Wings: veins on outer margin, and termen narrowly carrot red; cilia light brownish olive tipped with white; postmedial line fuscous. Forewing: costal edge cinnamon; a faint smoky antemedial shade, outangled on costa; a faint dark line on discocellular; postmedial line fine obliquely downbent, angled at vein 7 and inbent. Hindwing: the line medial. Wings below more thickly irrorated with fuscous. Forewing: a small whitish spot at discocellular; line thicker, slightly outbent to vein 4, then incurved; veins from cell, and a patch on termen from vein 7, below 4 forming a narrow line to tornus carrot red. Hindwing: the line postmedial, vertical and excurved to vein 5 somewhat outcurved across veins 4 and 3, and inbent to inner margin. Expanse: 37 mm. No locality on specimen. Type in Berlin Museum, ex Collection Staudinger. Wing shape as in *bilinea*, the lines very different.

C. putidula *Dogn.* (87 g). *Male*: Body greyish olive with some black scales. Forewing: basal third whitish expanding to beyond cell and on costa to outer line, irrorated with dark greyish olive and black; a faint medial pinkish cinnamon shade on which is a sayal brown discocellular point; costal edge sayal brown; outer line white outbent from costa with a small dark spot on it, sharply angled at vein 8 near termen, slightly inbent to inner margin, almost subterminal, the outer edge diffusely white, inwardly with a broad deep greyish olive shade, and a similar shade along termen. Hindwing to line and on termen deep greyish olive; line white, outwardly diffuse from costa before apex, straight to anal angle; a whitish shade medially. Forewing below as above but the cell and costa to outer line suffused with pinkish cinnamon. Hindwing below light drab; line fine, dark greyish olive, subterminal and slightly irregular. Expanse: 40 mm. San Antonio, Cali, Colombia. Forewing with apex acute, the outer margin straight, the hindwing with anal angle acute.

Group 4.

The following species have the wings usually more produced and acute: they are also somewhat larger and more robust.

C. joanna *Schs.* ♀ (= *lacuna* *Schs.* ♂) (87 g). *Male*: Head and thorax light vinaceous cinnamon. Abdomen pinkish buff, the anal hairs snuff brown tipped with fuscous black. Forewing light pinkish cinnamon to line, also costa to apex; the medial area from cell to inner margin light pinkish cinnamon; a black point on discocellular; a postmedial thick fuscous line, inbent from costa to inner margin followed by a finer line, not reaching costa, and then by a dark shade upcurved to apex; the space between the lines cinnamon drab; termen pale brownish drab. Hindwing light pinkish cinnamon from base to line and along inner margin to angle; the lines as on forewing, the first almost medial, not reaching inner margin. Wings below paler

with a few scattered black scales; postmedial line single, more remote from cell, faintly sinuous on forewing, more so on hindwing; diffuse dark shading on terminal space. *Female* (joanna Schs): Wings cinnamon from base to the line which is double from just beyond middle of wing on costa of forewing to middle of inner margin on hindwing; terminal space purplish brown, the veins finely fuscous. Wings below clay colour, the line single, fine and faint, more remote from cell, outcurved on forewing, angled on hindwing below vein 3. Expanse: male, 47 mm; female, 65 mm. Costa Rica; Venezuela; French Guiana.

undiscata.

C. undiscata Dogn. (87 g). *Male*: A close ally of *joanna*, differing in the genitalia. Body and wings cinnamon, including the termen; the line followed by a dark shade expanding at costa to apex; a few black scales at tornus of forewing; the double line of hindwing followed by black scales above vein 3, increasing near costa. Wings below pinkish cinnamon. Forewing: a faint black line on discocellular; the line fine, slightly curved; some dark suffusion at apex and from vein 3 to tornus, with a few black scales. Hindwing with the line fine and faint. Expanse: 50 mm. São Paulo, Brazil; also from Sta. Catharina in the Berlin Museum.

viemanda.

C. viemanda sp. nov. *Male*: Very similar to *joanna*, but larger. The wings to line light pinkish cinnamon, the fine outer fuscous line and buffy brown shade preceding it both outangled above vein 7, the fuscous shade following it extends to apex. The black irrorations beyond line of hindwing much denser and more extensive. Easily distinguished from *joanna* by the outangled line. The genitalia are very different. Expanse: 58—61 mm. São Paulo de Olivença, Amazons.

mulatro.

C. mulatro Schs. *Female*: Body cinnamon. Wings cinnamon buff. Forewing: a hair brown line on discocellular; outer line remote, snuff brown inbent from vein 7, there jointed by an extremely fine and faint dark line outbent from costa, followed closely by a series of small white fan shaped scales tipped with fuscous, connected by a diffuse faint and narrow brownish shade which branches at vein 7 to apex. Hindwing: line as on forewing almost antemedial. Wings below cinnamon buff; a stronger dark line on discocellular; a dark shade at apex above vein 8; no traceable line. Hindwing: a few scattered fuscous scales, some with white base; a short dark line beyond middle of inner margin. Expanse: 60 mm. Cayuga, Guatemala.

manalca.

C. manalca sp. nov. *Male*: Body light vinaceous cinnamon. Wings light pinkish cinnamon to line, termen slightly darker. Forewing: a few scattered black scales on basal half; a black point on discocellular; line tawny olive, very faint where outbent from costa, well defined from vein 7 to inner margin, above vein 3 followed by a fine similar shade continuing above vein 7 to apex, below vein 4 the shade faint, diffuse, expanding towards tornus. Hindwing: the line straight, medial, not reaching inner margin; black irrorations at base and beyond line. Wings below light cinnamon buff with scattered black scales. Forewing with line fine and faint; discal point as above. Hindwing: a small black point on discocellular; line faint, downturned at inner margin as a dark lunule. Expanse: male, 52 mm; female, 53 mm. French Guiana. Type in Carnegie Museum, Pittsburgh.

unalca.

C. unalca Schs. *Male*: Belongs to the group of *joanna*. Forewing longer and narrower. Body light pinkish cinnamon. Wings to line pale ochraceous buff; the line fine, tawny olive, outwardly edged by a slightly paler shade and then by a broader saccardo's umber shade irrorated with black scales. Forewing: a black point on discocellular; termen light drab; the line slightly outcurved at costa. Hindwing: line straight, postmedial, the black irrorations increasing towards inner margin; termen broadly buffy brown. Wings below pale ochraceous buff. Forewing: space above cell to subcostal and to beyond cell with rough scales and a few black scales; apical and terminal spaces suffused with fuscous, the veins brown; the discal spot larger. Hindwing: a few scattered black scales; termen broadly buffy brown. Expanse: 56 mm. Omai, British Guiana.

madenus.

C. madenus sp. nov. *Male*: Body and wings cinnamon buff with a very few scattered black scales. Forewing: costa pinkish cinnamon; a fine sinuous hair brown line on discocellular; no outer line; termen narrowly and cilia snuff brown, the cilia tipped with white. Hindwing similar but without any marking on discocellular. Wings below somewhat paler, outer margin of forewing more of a pale cinnamon pink. Expanse: 42 mm. Amazons, Brazil. Type in Cornell University Collection.

hamata.

C. hamata Wkr. (= *alcuna* Dogn.) *Male*: Body and wings cinnamon irrorated with white black tipped scales, the line van dyke brown followed by a similar shade. Forewing: a light pinkish cinnamon spot on discocellular; the line outbent from costa, thin, outangled and broader to inner margin, the shade following it extended from angle to apex. Hindwing: the line medial; on both wings a line of darker scaling to tornus and anal angle. Wings below paler, irrorated as above. Forewing: discal spot larger, hair brown containing some pale scales; the line fine, faint, slightly wavy; dark scaling at apex and above tornus. Hindwing: a faint, wavy, postmedial line. Expanse: 45 mm. French Guiana. A specimen labelled *hamata* Wkr. by

Sir George HAMPSON is the same as the type of *alcuna* Dogn. *P. hamata* Wkr. was described as from Rio de Janeiro, and may represent a different race.

C. jaruga Jones. *Male*: Body and wings reddish brown; anal hairs fuscous. An indistinct antemedial *jaruga*. line; postmedial line well defined black, oblique from costa to vein 7, then nearly straight to middle of inner margin, followed by a narrow light shade and broad black suffusion forming a large triangular space at tornus from inner margin to vein 4 crossed by a pale band from vein 3 to inner margin, above vein 8 the black suffusion extends to apex; a pale discocellular bar slightly defined by fuscous; termen pale; cilia dark. Hindwing: a black medial band and obscure subterminal shade. Body and wings slightly irrorated with white scales tipped with black. Expanse: 60 mm. Guaruja, Santos, S. E. Brazil. The species is unknown to me and the description faulty. Owing to the peculiar black tipped white scales, it is evidently close to *hamata* and *camarinus*.

C. camarinus sp. nov. (87 h). *Female*: Body and wings fawn colour thinly irrorated above and below *camarinus* with fan-shaped white scales tipped with black; abdomen above somewhat suffused with purplish. Forewing: a faint sinuous darker antemedial line; a dark grey spot on discocellular inwardly edged with cinnamon drab; outer line remote from termen as in *gaujoni*, fine, dark from costa to below 8, then thick, fuscous to inner margin, outwardly edged with light quaker drab, and with dark suffusions at apex. Hindwing: line thick as on forewing before middle of wing. Wings below with lines fainter; discal spot on forewing oblique, edged with dark mouse gray; a dark discocellular streak on hindwing, the line outcurved, medial. Expanse: 60 mm. Iquitos, Peruvian Amazons. Type in the Berlin Museum.

C. euthymius sp. nov. (87 h). *Male*: Body light pinkish cinnamon, the anal hairs pale sayal brown. *euthymius*. Forewing: base pinkish cinnamon limited by a light pinkish cinnamon narrow antemedial shade well inbent along anterior edge of cell, outcurved below cell; space beyond to line purplish cinnamon; an oblique hyaline spot at discocellular cut by veins 5 and 4; outer line obliquely downbent and excurved, angled at vein 8, very fine, dark, inwardly well edged with light ochraceous salmon from below vein 7; a pale greyish vinaceous shade from apex below vein 9 incurved, and narrowing to termen at vein 2, the space before it to line from vein 4 to inner margin dusky fawn colour; termen from vein 8 to vein 3 dark olivaceous brown. Hindwing to line light vinaceous fawn; line as on forewing medial; terminal half fawn colour. Wing below to line light pinkish buff, partly cinnamon buff on fore wing irrorated with black. Forewing: the line fainter, with a black spot on it close to costa; the suffusions on termen benzo brown. Hindwing with the line outcurved almost subterminal, the pale color extending to termen from vein 3 to inner margin. Expanse: 52 mm. Bella Vista, Colombia. Type: Collection Niepelt.

C. moengus sp. nov. *Male*: Body and wings olive buff without any black scales, anal tufts *moengus*. olive brown. Forewing: a fine outbent pinkish buff antemedial line; a narrow oblique hyaline spot edged with pinkish buff at discocellular; outer line tawny olive, oblique from costa, angled at vein 7 and inbent, broadly preceded from within cell by an olive drab shade which continues to apex beyond and above angle of line; from angle the line is followed by a hair brown line, diverging slightly to inner margin, and a fine dark line from it at vein 4 to tornus; outer margin from vein 9 to near tornus pale olive buff, and a narrow dark olive buff line from vein 8 to vein 3, extending on cilia which are tipped with white. Hindwing: the line as on forewing from beyond middle of costa to a little below middle of inner margin. Wings below pale olive buff. Forewing suffused with olive drab except on inner and outer margin from apex to vein 3 beyond a patch following the line; outer line single. Hindwing: line fine, single, postmedial, slightly outcurved. Expanse: 59 mm. Moengo, Surinam. Type in Cornell University Collection.

C. gaujoni Dogn. (87 h). *Male*: Body and wings cinnamon buff irrorated with fuscous scales. Forewing: *gaujoni*. a faint wavy antemedial drab line; a black annulus on discocellular filled in with hair brown scaling; postmedial line hair brown from a little less than two thirds from base, outbent and excurved, rounded and inbent to near middle of inner margin, followed by a diffuse narrow brown shade continuing to apex above vein 7; termen narrowly buffy brown. Hindwing: a hair brown line from middle of costa to middle of inner margin followed by denser irrorations except on termen. Wings below with few irrorations, the lines fine, faint, lunular, on hindwing subterminal from costa, at vein 5 inbent to inner margin; the discal spot on forewing black, containing some whitish scales, the apex with dark suffusions. Expanse: male, 52—60; female 55—88 mm. Loja, Ecuador.

C. candacus sp. nov. *Male*: Body and wings light pinkish cinnamon; some black irrorations on *candacus*. head, collar, and thorax; abdomen above thickly irrorated with black. Forewing: antemedial line benzo brown, wavy, inbent, interrupted across cell; a hair brown annulus on discocellular filled in with greyish buff; outer line cinnamon drab, outbent and excurved, inbent from vein 7, followed by greyish olive shading irrorated with black, at vein 7 upbent to apex, below vein 4 expanding to tornus; a few scattered black scales on basal area and still fewer on medial area. Hindwing: a patch of black scales at base; the line medial followed by black

scaling from vein 6, expanding to inner margin. *Female*: Body and wings fawn colour, the lines black. Forewing: discal spot large, almost entirely black; the black scaling beyond outer line more intense and broader. Expanse: male, 52 mm; female, 75 mm. French and British Guiana; Ponte Nova, Rio Xingu; Tefte, Amazons. Type in the U. S. National Museum.

callipius. **C. callipius** *sp. nov.* (87 h). Allied to *gaujoni*, darker in colour, the outer line more remote from base. *Male*: Body and wings avellaneous fawn irrorated with black. Forewing: a faint, sinuous, darker antemedial line; a deep mouse grey annulus on discocellular filled in with pale scales; postmedial line fine, buffy brown, oblique and excurved from costa beyond two thirds from base, angled below vein 8 and inbent to beyond middle of inner margin followed by denser irrorations except a triangular patch on termen broad at vein 6 ending in a point at vein 2. Hindwing: the transverse line before middle of wing broadly followed by denser irrorations, and a patch of same on inner margin near base; cilia on both wings buffy brown tipped with white. Wings below more evenly and thinly irrorated with black. Forewing: discal spot oval; outer line faint, from a small spot on costa and followed by dark mottlings from vein 3 to tornus. Hindwing: the line faint, irregular, postmedial. Expanse: male, 47 mm; female 60 mm. Arouary, Cayenne. Type in the Berlin Museum.

marona. **C. marona** *Schs.* *Male*: Body and wings cinnamon buff. Abdomen with a few scattered black scales and lateral darker spots. Forewing: antemedial line faint, fine, pinkish cinnamon, slightly inset from median; discal spot oblique, finely outlined, tawny olive; outer line oblique from costa, angled and inbent at vein 7, tawny olive followed below vein 4 by a few black scales and dark grey spots, oblique to tornus, these spots irrorated with black. Hindwing: some black scaling along inner margin from base, and beyond the medial line from below vein 6, followed by small dark spots as on forewing from below vein 5, not approaching termen. Expanse: male, 51 mm; female, 64 mm. French Guiana. Closely allied to *candacus*.

bactriana. **C. bactriana** *Blr.* Sex? Sericeous pale reddish brown irrorated with blackish with usual oblique elbowed line dark grey; cilia reddish brown intersected by a darker line. Forewing: an oblique grey spot on discocellular, a grey spot above latter on costa; a small black dot in middle of cell; an antemedial <-shaped grey marking below cell, and a black spot near base; outer line followed by slight greyish suffusion. Hindwing: discal area greyish. Wings below more distinctly irrorated with black; outer line of forewing broken up into grey spots; discocellular spot as above. Hindwing: an arched discal series of blackish ^-shaped markings. Abdomen speckled with black. Expanse: 55 mm. Paramacu forest, Amazons. I have seen nothing to fit BUTLER'S description.

funbris. **C. funbris** *Schs.* (87 h). *Male*: Body and wings sepia, the line fine, black. Forewing: a faint darker antemedial line; a small darker annulus on discocellular; postmedial line oblique, excurved and angled at vein 7. Hindwing: the line medial, almost antemedial. Wings below with the line more remote, on forewing parallel with termen, on hindwing postmedial, partly crenulate, both wings with a fine black line on discocellulars. *Female*: Body and wings buffy brown. Forewing: the annulus larger. Wings below; the line placed as in male, crenulate on both wings; forewing with an oblique spot on discocellular, the hindwing with a small spot. Expanse: male, 46 mm; female, 62 mm. Castro, Parana, Brazil.

magnapuncta. **C. magnapuncta** *Kaye*. I have not seen any specimens of this species. *Female*: Wings pinkish ochraceous, the lines greyish black. Forewing: antemedial line wavy, lunular, interrupted in cell; a large annulus at discocellular; an outer line remote from apex on costa, oblique, angled above vein 6 and inbent, passing close to annulus. Hindwing with the line antemedial. Expanse: 62 mm. Tabaguite, Trinidad, British West Indies. The sex is not mentioned in description, but the outline shows it is a female. No other species of this group has the line so close to discal spot.

producta. **C. producta** *Dogn.* (87 h). *Male*: Body and wings to line sorghum brown; the line broad, fuscous followed by a light vinaceous fawn shade; the termen suffused with sorghum brown. Forewing: an army brown antemedial, slightly inbent line; a fine dark streak on discocellular; the outer line deeply outangled with a sorghum brown streak on costa to apex. Hindwing: the line medial. Wings below similar, but the disc of forewing cinnamon rufous. *Female* with the apex of forewing not produced, the hindwing with rounded termen. Body and wings pinkish cinnamon, the line broad, snuff brown, followed by a broad pale pinkish cinnamon shade. Forewing with a dark line on discocellular. Wings below similar; a dark line on discocellular of hindwing also. Expanse: male, 36 mm; female, 42 mm. Popayan, Colombia.

plana. **C. plana** *Wkr.* (= *diagonalis* *H. S.*) (88 a). *Male*: Head and collar pinkish buff suffused with olive buff. Abdomen cinnamon drab. Forewing: base, costal margin to apex, inner margin to line, and a narrow shade outwardly edging line vinaceous buff; medial space to line at angle benzo brown; the line from costa fine, excurved and angled above vein 7, below 7 inbent and merely defined by the dark and light colouring; termen suffused with benzo brown irrorated with black; a vinaceous buff round spot containing a black line on discocellular. Hindwing similar to forewing, the line just beyond middle; cilia tipped with white. *Female*:

Body deep olive buff suffused with vinaceous buff. Wings to line light buckthorn brown; the line cinnamon brown followed by a broad pale pinkish cinnamon shade reaching apex above angle on forewing, the termen suffused with pinkish buff; scattered black scales chiefly on terminal space; cilia tipped with white. Underside of wings of both sexes paler, the line of forewing excurved from costa, incurved between veins 7 and 4, again between 4 and 3, then deeply incurved to inner margin; the line on hindwing outcurved and partly crenulate. Expanse: male, 37 mm; female, 47 mm. Brazil. Two males and females in the Berlin Museum, probably *Herrich-Schaeffer's* types. The species is in no way related to *orthane* as given in Kirby but the description fits the figure of *diagonalis*.

C. anysia *sp. nov.* (88 a). *Male*: Palpi and throat ochraceous buff; frons fuscous; vertex cinnamon brown; *anyisia*. collar, thorax and abdomen avellaneous; second segment of abdomen dorsally hair brown. Wings to line light cinnamon drab suffused with avellaneous. Forewing: costal edge mikado brown, also basal third of subcostal, the space between at base brownish drab; an antemedial dusky drab line across cell joined at median by a faint similar streak from base; a large quadrate sayal brown spot in end of cell with a similar narrow shade from it to near base of inner margin; an oval vinaceous buff spot at discocellular; postmedial line broad, fuscous at costa, outangled below vein 7, fine, inbent, mostly natal brown to inner margin, followed by lilacine scaling from vein 6 to vein 3; then by a thick natal brown shade upcurved to apex, this shade bifurcating below vein 4 the outer branch extending to termen at tornus, and enclosing in bifurcation from below vein 4 to vein 2 a tawny spot; outer margin from vein 2 to apex, also costal margin beyond postmedial line, and above inner margin light brownish drab; cilia natal brown. Hindwing: the line fuscous, medial; outer space light brownish drab, the termen shaded with sanford's brown, more broadly from vein 5 to inner margin. Forewing below clay colour, the inner margin broadly pinkish buff; a large round black spot at discocellular; termen narrowly light drab with a benzo brown streak below vein 19 to apex; faint traces of a subterminal line. Hindwing below warm buff without markings; cilia cinnamon brown. Expanse: 50 mm. Pied Saut, Oyapok River, French Guiana. Type in the Carnegie Museum. Forewing with apex produced.

Subfamily: **Lacosominae.**

Key to the genera.

A. Veins 7 and 8 stalked.

a. Cell of forewing normal.

a¹. Vein 5 on forewing from middle of discocellular.

a². Antenna pectinated to tips.

a³. Forewing with tornus excised.

a⁴. Forewing broad, apex not produced

b⁴. Forewing broad, apex produced

b³. Forewing with tornus wavy.

a⁴. Forewing broad, not produced, termen nearly straight

b⁴. Forewing broad, apex acute usually produced, termen usually inbent

c³. Forewing with tornus crenulate

d³. Forewing with tornus acute

e³. Forewing with tornus rounded.

a⁴. Vein 2 on hindwing close to 3

b⁴. Vein 2 on hindwing not close to 3

a⁵. Termen even

b⁵. Termen sinuous

c⁵. Termen slightly angled at vein 3

b². Antenna serrate at tips.

a³. Forewing with apex produced, falcate

b³. Forewing with apex not produced

b¹. Vein 5 from below middle of discocellular.

a². Forewing with apex produced, falcate.

a³. Frenulum highly developed

b³. Frenulum not highly developed

b². Forewing broad, not falcate.

a³. Hindwing crenulate

b³. Hindwing rounded.

a⁴. Apex acute

b⁴. Apex not acute

b. Cell of forewing long

B. Veins 6—8 stalked.

a. Veins 3 and 4 stalked

b. Veins 3 and 4 not stalked

1. Genus: **Trogoptera** H.-Schäff.

Male: Frenulum present. Antenna bipectinate. Palpi short, upturned, hairy. Legs mostly hairy; hind tibiae with long hairs and terminal spurs. Forewing: costa straight, slightly convex at tip, apex acute; outer margin straight to vein 3, excurved between 3 and 2, and more deeply excised at tornus and inner margin; vein 2 from well before middle of cell; 3 before angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 moderately stalked; 9 and 11 from well before end of cell, close together; 10 as a spur from 9. Hindwing: costa slightly convex to middle, excurved to tip of vein 8, and more deeply excurved at apex; below vein 7 termen slightly rounded; vein 2 from beyond middle of cell; 3 before angle; 4 from lower angle; 5 from middle of discocellular which is oblique; 6 from upper angle; 7 from close to end of cell; cell less than half the length of wing.

Type: *T. erosa* H.-Schäff.

erosa. **T. erosa** H.-Schäff. (88 a). *Male*: Body and wings olivaceous drab. Forewing: costal margin suffused with whitish; a fine postmedial dark line slightly outangled on costa. Hindwing with termen denticulate. Expanse: 33 mm. Brazil. 1 ♀ in Mus. Berlin e coll. Maassen.

excavata. **T. excavata** Wkr. (88 a). *Male*: Body and forewing pinkish buff, the hindwing cinnamon buff, all with scattered fuscous scales. Forewing: a paler streak on discocellular; postmedial line very fine and faint, hair brown, better marked at inner margin, followed by a slightly darker shade, oblique from vein 5; cilia wood brown tipped with white, also on hindwing which has no markings. Wings below pale pinkish cinnamon with a few scattered dark scales; fine black streaks on discocellulars; line of forewing forming a black spot on costa and short line at inner margin; some buffy brown shading on termen below apex to vein 4 on forewing; hindwing with a dark postmedial line on costa. Expanse: 39 mm. Rio de Janeiro, Sta. Catherina, Brazil.

notata. **T. notata** Wkr. (88 a). *Male*: Head and collar light ochraceous buff. Thorax and abdomen pale pinkish cinnamon. Forewing to line pinkish buff with a few dark scales; traces of a fine antemedial line; a black streak on discocellular; postmedial line slightly outcurved, black and well marked on costa, then faint, well defined from vein 5 to inner margin; termen ecru drab suffused with light cinnamon drab from vein 4 to inner margin; cilia tipped with white, at excisions the base fuscous. Hindwing pinkish cinnamon, at apex light drab grey; a fine dark medial line straight from costa to inner margin above anal angle; cilia buffy brown tipped with white. Wings below tiller buff with a few dark scales; black spots on discocellulars. Forewing: a thick postmedial black line on costa then almost obsolete; better marked from vein 4 to inner margin. Hindwing: a faint curved medial line heavily marked on costa. Female cinnamon buff with lines fine. Expanse: male, 30 mm; female, 36 mm. Castro, Parana; São Paulo, S. E. Brazil. — **guianaca** *subsp. n.* (88 a) *Male*: Body and wings avellaneous irrorated with a few snuff brown scales; cilia slightly tipped with white. Forewing: a very faint, fine antemedial line; a discocellular narrow spot defined by darker edging; postmedial line broader on costa, outangled and inbent, slightly sinuous followed by a hair brown patch between veins 2 and 5; costal edge sayal brown. Hindwing without line. Wings below mostly suffused with pale drab grey irrorated with black; black streaks on discocellulars. Forewing: postmedial line faint, more outcurved, termen broadly cinnamon rufous except at apex and tornus. Hindwing: a faint outcurved medial line, the termen narrowly cinnamon rufous. Expanse: male, 34 mm; female, 41 mm. French Guiana; Amazons; Merida, Venezuela. Genitalia slightly different from *excavata*.

althora. **T. althora** *sp. n.* (88 a). *Male*: Body and wings light tawny olive suffused with light pinkish cinnamon with a few scattered darker scales. Forewing: costal edge olive buff; outer half of costa suffused with pale vinaceous fawn; a black line on discocellular outwardly pale edged; outer line remote, dark, thicker on costa, slightly outcurved, very faint from vein 6 to inner margin, followed by a large dull fuscous patch from vein 4 to inner margin; cilia darker, tipped with white at excisions. Hindwing: a very fine dark medial line; cilia tipped with white. Wings below to line pinkish buff; prominent black spots on discocellulars, a postmedial drab shade outwardly edged with pallid mouse grey; termen of forewing from vein 8 to vein 3 verona brown and some similar shading on hindwing at apex; cilia tawny olive tipped with pinkish cinnamon on hindwing. Expanse: 31 mm. Cayuga, Guatemala. — Specimens from Costa Rica are larger, expanse 37 mm, the cilia at excisions sometimes roseate; there is no difference in the genitalia. — **noaha** *form n.* *Male*: Body and wings like *althora* without the light pinkish cinnamon suffusions. The wings below with a very faint pinkish tinge on basal half, costal edge of forewing avellaneous. The genitalia slightly different. Expanse: 29 mm. Jalapa, Mexico. — **mahlaha** *form n.* *Male*: Head, collar and thorax pale pinkish cinnamon. Forewing to line and on costa to apex pale pinkish cinnamon; costal edge avellaneous; termen and hindwing avellaneous irrorated with fuscous scales; a black discal point on forewing and the line fine, dark, outcurved and well inbent; cilia fuscous tipped with white; no line on hindwing. Underside paler; a small black point on both wings; line on fore-

wing from a small fuscous spot on costa; a postmedial dark shade on costa of hindwing. Expanse: 38 mm. Loja, Ecuador. — **jonica** *subsp. n.* (88 b). A subspecies of *althora*, differing somewhat in the genitalia, and in the more crenulate hindwing. *Male*: Head brownish. Body and forewing light vinaceous fawn with a few black scales. Forewing: costal edge zinc orange; a fine dark antemedial line; a dark point at discocellular; postmedial line better defined, hair brown, angled below vein 8 and inbent to middle of inner margin, followed below vein 5 by a deep mouse grey shade expanding to tornus; cilia buffy brown tipped with white on interspaces. Hindwing cinnamon drab irrorated with black; cilia as on forewing. Wings below paler with fuscous lines on discocellular and a postmedial fine dark line outcurved on both wings. Expanse: 27 mm. Paraguay. — **micalha** *subsp. n.* (88 b) from Misantla, Mexico; the genitalia differ slightly from *althora*. *Male*: Body and forewing vinaceous buff suffused with olive buff, the hindwing wood brown, both wings with a few scattered black scales; cilia tipped with white. Forewing: costal edge avellaneous; a whitish oblique streak preceded by a few black scales on discocellular; the line fine, broader on costa, outcurved and inbent to middle of inner margin, followed by hair brown suffusions from vein 5 to inner margin. Hindwing: a faint black streak on discocellular and fine straight postmedial line. Wings below tilleul buff, with benzo brown suffusions on termen; black points on discocellulars; outer line thick, hair brown, much fainter on hindwing except at costa; cell and base of forewing pinkish buff. Hindwing with termen evenly rounded. Expanse: 27 mm.

T. tirzaha *sp. n.* *Male*: Body and wings avellaneous fawn. Forewing: costal edge cinnamon; costal margin from antemedial line, apex and a subterminal incurved shade pale cinnamon pink; lines fine, benzo brown, the antemedial slightly inbent, the postmedial outcurved and slightly incurved close to a pale cinnamon pink spot at discocellular; cilia buffy brown tipped with white. Hindwing: a fine medial line. Forewing below pale cinnamon pink; a black discal point; line thick, well outcurved from costa; a mikado brown patch on termen. Hindwing below light pinkish cinnamon; a short black streak at discocellular; line postmedial, faint, except on costa; some terminal buffy brown from vein 7 to vein 4. Expanse: 30 mm. Chiriqui, Panama.

T. sao *Drc.* The species is unknown to me. *Male*: Wings orange brown, costal margin of forewing and a faint line crossing the wing from costa to inner margin pinkish brown. Body yellowish brown. Expanse: 44 mm. Rio Sudio, Costa Rica.

T. belilia *sp. n.* *Male*: Body and wings cinnamon buff with a very few black scales. Forewing: a faint, darker, antemedial line; some black and pale cinnamon pink scales at discocellular; postmedial line from a black spot on costa, almost obsolete, inbent from vein 4 to inner margin, hair brown; cilia buffy bronze tipped with white; termen from vein 5 to inner margin suffused with cinnamon drab. Hindwing without a line; cilia as on forewing. Forewing below pale pinkish buff; discal and costal spots black; line faintly traceable; a sayal brown patch on termen. Hindwing below light vinaceous cinnamon; a black point at discocellular; some flesh ocher scaling postmedially from veins 5—2. Expanse: 30 mm. Ponte nova, Teffé, São Paulo de Olivença, Amazons.

T. maroniensis *Dyar* (= *maroniensis* *Dogn.*). *Male*: Body and wings apricot buff with a few dark scattered scales. Forewing: faint traces of a darker antemedial line; a fine dark line outwardly edged with white on discocellular; outer line fine, fuscous, remote from apex, slightly excurved between veins 10 and 6, then inbent to inner margin at middle; terminal area suffused with neutral grey except at inner margin. Hindwing: the line medial to inner margin above anal angle. Hindwing below with the line somewhat outcurved. Expanse: 26 mm. Maroni River, French Guiana. The type of *maroniensis* *Dogn.* has the outer line on forewing straighter from costa.

T. callinica *sp. n.* (88 b). *Male*: Head pinkish cinnamon. Collar and thorax white suffused with pale ochraceous buff on front of collar and tegulae. Abdomen pale pinkish cinnamon, the specimen partly discoloured. Forewing light pinkish cinnamon; traces of a wavy antemedial line; a black streak on discocellular; postmedial line thick, black, vertical from costa passing close to cell. Hindwing pinkish cinnamon; a black point on discocellular; a black medial line from costa to lower angle of cell; cilia unicolorous with wing. Expanse: 26 mm. Rio Grande do Sul. Type from Collection Staudinger (Mus. Berlin).

T. salvita *sp. n.* (88 b). Allied to *jonica*. *Male*: Head and abdomen vinaceous fawn; thorax vinaceous buff. Forewing pale vinaceous cinnamon to postmedial line and on terminal space from vein 3 to inner margin, otherwise beyond line pallid purplish grey; line postmedial, fine, sayal brown, outcurved with traces of angle below vein 8, inbent to middle of inner margin; a fine antemedial line; costal edge cinnamon. Hindwing vinaceous cinnamon, somewhat greyish at apex; a fine medial line; cilia of both wings verona brown tipped with white on interspaces. Expanse: 30 mm. Casa Branca, Sta. Catherina, Brazil.

T. semililacea *Dogn.* *Male*: Body light vinaceous cinnamon; some dark hairs in anal tuft. Wings from base to outer line pale cinnamon pink, the base broadly suffused with salmon colour; outer portion of wings purplish tawny olive, inwardly edged by a fine darker line; black discal points. Forewing: the outer area with

the line not reaching above vein 6; terminal pale cinnamon pink suffusions from vein 5 to tornus. The cilia of excision at tornus fuscous tipped with white. Hindwing: the line medial and straight to anal angle; cilia at tornus fuscous, some of the cilia tipped with white. Wings below duller, the black discal points more distinct. Expanse: 32 mm. St. Laurent, Maroni, French Guiana; São Paulo de Olivença, Amazons.

rumina. **T. rumina** *Drc.* *Male*: Body and wings buff yellow with a few purplish scales; cilia benzo brown irregularly tipped with white. Forewing: traces of a faint, wavy, drab; antemedial line; outer line consisting of a purplish lunule on costa, and similar lunules between veins 3 and 1, these latter followed by a brownish vinaceous shade to tornus, its upper edge oblique from vein 3; a small similar patch below vein 5, and small spot on discocellular. Hindwing: a purplish streak on inner margin above anal angle. Forewing below with the base brownish vinaceous; discal spot better marked. Hindwing: below a dark streak on discocellular; traces of a subterminal curved line better defined at costa and from vein 3 to inner margin, on costa followed by a white spot. Expanse: 25 mm. Guapiles, Costa Rica; Taboga Island, Panama.

mana. **T. mana** *sp. n.* *Male*: Body and forewing to line cinnamon drab. Forewing: a black streak on discocellular; postmedial line slightly incurved at costa, then vertical to excision on inner margin, fine, white; terminal space fuscous; cilia at excision fuscous tipped with light greyish buff. Hindwing with inner margin extending as far as tip of abdomen, sayal brown; a black line on discocellular. Forewing below to line sayal brown; discal black streak outwardly edged with white; the white postmedial line broader; termen fuscous, at apex drab grey. Hindwing below cinnamon drab; discal streak black and white; traces of a postmedial line defined by pale drab grey scaling; a dark shade at apex. Expanse: 33 mm. Mana River, French Guiana. Type in Carnegie Museum, Pittsburgh.

subrufescens. **T. subrufescens** *Dogn.* (88 b). *Male*: Head brazil red. Body cinnamon drab. Wings to line cinnamon drab; black lines on discocellulars; postmedial line fine, black, almost vertical; a few black irrorations. Forewing: a faint darker antemedial line; postmedial followed from vein 8 by a fuscous shade, at vein 5 expanding to tornus; a terminal auburn shade from vein 7 to vein 3; apex cinnamon drab; cilia tipped with white on interspaces, with black spots at veins. Hindwing: the line medial followed by a fuscous shade expanding to anal angle; termen broadly auburn; cilia as on forewing. Forewing below to line, except on inner margin, brazil red; black discal spot larger; terminal space pale brownish drab; a terminal auburn patch from vein 8 to near vein 4. Hindwing below brownish drab, broadly paler along outer edge of line; termen broadly auburn. Expanse: 35 mm. Monte Tolima, Colombia.

grisea. **T. grisea** *Schs.* (88 b). *Male*: Forewing less acute, crenulate at tornus of forewing. Hindwing with termen as in *amilia*, but less prominent. Body and wings light buff irrorated with fuscous black scales, more thickly on wings than usual. Forewing: an interrupted fine dark antemedial line from a small fuscous black spot on costa, vertical and sinuous; an oblique hyaline spot at discocellular partly edged with fuscous; outer line fine, benzo brown, crenulate and excurved to below vein 7, followed by dark spots or annuli from vein 4 to vein 1. Hindwing: a broken subbasal line; a postmedial benzo brown crenulate line followed by whitish buff and a dark lunular line. Wings below with the markings reduced. Expanse: male, 30 mm; female, 45 mm. Castro, Parana; Passa Quatro. Minas. The species varies in the intensity of the lines.

2. Genus: **Reinmara** *gen. nov.*

Male: Antenna bipectinate, very short on terminal third. Frenulum present. Palpi upturned, smoothly scaled, short. Forewing: apex strongly produced, not acute; termen oblique, incurved below apex to vein 2, and well excised to tornus; vein 2 from middle of cell; 3 near 4; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 moderately stalked. Hindwing broad from costa to anal angle; termen rounded, slightly incurved below apex; anal angle acute; cell short; vein 2 towards end of cell; 3 nearer 4 than 2; 4 lower angle; 5 middle of discocellular; 6 from upper angle; 7 before angle. Genitalia except gnathos like *Trogoptera*.

Type: *R. enthona* *Schs.*

enthona. **R. enthona** *Schs.* (88 b). *Male*: Head and collar light pinkish cinnamon. Thorax pale cinnamon pink. Abdomen pinkish buff (type), more frequently cinnamon buff, the anal hairs fuscous. Wings to outer line clay colour, terminal area cinnamon-rufous; cilia tipped with white. Forewing: white scaling at base, below costa to antemedial line, and before outer line; antemedial line darker, almost vertical; some fuscous scaling edged with white on discocellular; outer line bister, outangled at vein 11 and inbent to inner margin beyond middle, slightly sinuous, some whitish scaling distally towards costa; a slight vinaceous fawn shade on termen from vein 7 to vein 3, its inner edge curved. Hindwing: a fine dark medial line from costa to below middle of inner margin. Wings below clay colour with some fuscous black irrorations; black streaks on discocellulars with a few white scales. Forewing: the outer line from a black spot at costa fine, sayal brown, crenulate, sub-

terminal, partly edged with whitish scaling. Hindwing: line postmedial, outcurved, crenulate, the white scaling extending to termen at anal angle. Expanse: 43 mm. French Guiana; Rio Xingu, Amazons.

R. minasa *sp. n.* (88 b). *Male*: Body pinkish cinnamon. Forewing: base below cell buff pink limited by an outcurved dark antemedial line; medial space vinaceous fawn, the costa suffused with clay colour to base; an oblique pale greyish vinaceous spot on discocellular; outer line bister, inwardly edged with pale greyish vinaceous, straight and inbent to inner margin, outwardly edged with cinnamon and a bister shade from apex to inner margin; termen sayal brown with a terminal pale greyish vinaceous shade including cilia from vein 8 to vein 3. Hindwing clay colour; line medial to inner margin before angle, saccardo's umber, fine, single, inwardly edged with vinaceous pink, and a similar shade at apex. Wings below dark vinaceous cinnamon; black spots on discocellulars. Forewing: the line represented by a light pinkish shade expanding to tornus, inwardly defined by a dark smoky shade towards inner margin; a bister patch on termen from apex to vein 3. Hindwing: the line postmedial, obliquely inbent to inner margin from vein 4, defined inwardly by smoky shading. Expanse: 35 mm. Passa Quatro, Minas, Brazil. Type in Mus. Berlin. *minasa.*

3. Genus: **Druentia** *gen. nov.*

Male: Frenulum slight. Antenna bipectinate, very short on terminal fourth. Palpi upturned, reaching frons. Legs hairy; hind tibiae with terminal spurs. Forewing: apex acute, not produced; outer margin almost straight, inbent, sinuous below vein 3; vein 2 well before middle of cell; 3 near angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 moderately stalked; 9 and 11 from cell. Hindwing costa convex; apex to vein 6 slightly sinuous or rounded in the same species, below vein 6 rounded and inbent, the anal angle acute; vein 2 from beyond middle of cell; 3 near lower angle; 4 from angle; 5 from middle of discocellular; 6 from upper angle; 7 from before angle.

Type: *D. partha* Schs.

D. partha Schs. (88 b). *Male*: Body and wings cinnamon buff with a purplish tinge and a few scattered fuscous scales. Forewing: outer line fine, sayal brown outwardly pale edged, oblique on costa with a short black streak on it, outbent along vein 8, acutely angled and inbent; a small pinkish buff spot at discocellular; inwardly edged by a few sayal brown scales. Hindwing: a black point with some pinkish buff scales on discocellular; line as on forewing, postmedial, straight from costa to inner margin near angle; cilia on both wings mostly saccardo's umber. Forewing below as above, the line very faint, wavy, incurved below vein 3; a pale pinkish buff shade on termen from vein 6 to tornus. Hindwing below light buff, the line more remote, very faint, slightly incurved from costa, inbent from vein 4 to inner margin. Expanse: male, 37 mm; female, 42 mm. Guatemala; Costa Rica; Colombia; Amazons; French Guiana. Forewing with apex acute, outer margin nearly straight, inbent, sinuous from below vein 3. Hindwing slightly crenulate from apex to vein 6. *partha.*

D. inscita Schs. (88 c). *Male*: Body and wings light vinaceous fawn irrorated with fuscous and suffused with ecru-drab. Wings: the line as in *partha*, brownish olive outwardly edged with white; a black discal point on forewing with some pale scaling outwardly and a minute black point on hindwing. Forewing below greyer, the costal margin to line light pinkish cinnamon; line finer. Hindwing below: the line faint but placed as above. Expanse: male, 23—34 mm; female, 40 mm. Mexico to Amazons and French Guiana. Shape of forewing like *partha*, the termen at tornus less sinuous. Hindwing with the apex rounded. *inscita.*

D. scissa H.-Schaeff. (= *inscitoides* Dogn.). *Male*: Very similar to *inscita*. Forewing: the outer line from apex slightly incurved, the oblique line from costa imperceptible; an oblique line on discocellular. A black spot on discocellular of hindwing. Expanse: 24 mm. Rio Madeira, Amazons. *scissa.*

D. macallia *sp. n.* (88 c). *Male*: Similar to *inscita*. Differs in having on forewing a small round hyaline spot inwardly edged with fuscous at discocellular; the angle of outer line fuscous. Hindwing below with a small black discal point; the line slightly outcurved, ending further above anal angle. Expanse: 32 mm. Mocoa, Colombia. Type in Collection W. Hopp-Charlottenburg. *macallia.*

D. zikana *sp. n.* (88 c). *Male*: Similar to *inscita*. Body and wings to line light cinnamon buff, with a few scattered dark scales; the line broader, light brownish olive, the white on outer edge broader; a marginal diffuse wood brown shade; black points on discocellulars; cilia dark brown partly tipped with white. Hindwing below whitish, the line defined in transparency. Expanse: 30 mm. Canipobello, Province of Rio de Janeiro, Brazil. Collected by Zikan. Type in Mus. Berlin. *zikana.*

D. caquetensis *sp. n.* (88 c). *Male*: Body and wings avellaneous with scattered black scales; abdomen dorsally darker shaded, the anal tufts fuscous black. Forewing: costal edge buffy brown; a faint pale fawn colour wavy antemedial line, and a minute cluster of black scales on subcostal; a minute black and pinkish *caquetensis.*

buff spot on discocellular; the outer line oblique, fine, with a black lunule from vein 9 to vein 8, outbent along vein 8 and angled before termen, then straight to inner margin, subterminal, olive brown slightly expanding; cilia olive brown tipped with white. Hindwing: a small black spot on discocellular; line as on forewing, postmedial, straight to inner margin at anal angle, outwardly pale shaded; cilia as on forewing. Wings below tiller buff irrorated with black; line fine and faint, hair brown; cilia as above. Forewing with the anterior portion of wing to line suffused with pinkish cinnamon, the discal spot pinkish buff. Expanse: 31 mm. Caquete, Colombia. Type in Coll. W. Hopp-Charlottenburg.

fatella. **D. fatella** Schs. *Male*: Body flesh-ocher; the lateral tufts on last segment and long anal hairs fuscous black. Forewing: base to near outer line apricot buff with a silvery white streak on discocellular; a pale purplish vinaceous shade before the line, which is fine, dark on costa, outangled at vein 8, then black outwardly edged with silvery white, and again with black from vein 4 to inner margin; space beyond cinnamon, suffused above vein 4 to vein 7 with pale purplish vinaceous subterminally and terminally. Hindwing: base to line as on forewing; line medial, double from costa to inner margin below middle; outer half cinnamon broadly suffused terminally from below vein 7 to vein 3 with pale purplish vinaceous also subterminally from vein 4 to near inner margin. Forewing below duller; the white discal spot crossed by a dark line; outer line fine, hair brown, outcurved, below vein 3 incurved; a large cinnamon patch on margin from vein 8 to vein 4, and again from vein 3 to inner margin. Hindwing: the line postmedial, outcurved and partly crenulate; termen from costa to vein 4 broadly cinnamon. Expanse: 34 mm. St. Jean, French Guiana.

ursmara. **D. ursmara** sp. n. *Female*: Head and collar deep brownish drab shading to light brownish drab on thorax. Abdomen above orange cinnamon, the last segment and underside light brownish drab. Forewing to line russet; an outcurved darker antemedial line; a dark line on discocellular outwardly edged with pale greyish; postmedial line black, thick, faintly outcurved; terminal space light vinaceous drab with a few sepia irrorations; costa, terminal narrow shading between veins 7 and 4, and cilia russet. Hindwing to line light brownish drab; a few dark scales on discocellular; line as on forewing, medial; outer half pale brownish drab with terminal russet shading. Wing below similar. Expanse: 34 mm. Incachaca, Bolivia.

muta. **D. muta** Dogn. *Male*: Termen of forewing more even, crenulate at tornus, of hindwing slightly excised at apex. Head, thorax and base of abdomen drab; frons, tip of tegulae and abdomen terminally pale drab grey. Forewing drab grey, the hindwing pale drab grey, both wings light drab beyond the outer line, and with a few scattered black scales chiefly on base. Forewing: traces of a brownish antemedial line from a dark point on costa; a black point on discocellular; outer line lunular, outbent on costa, inbent below vein 7, benzo brown, outwardly edged with light buff and again with brown from vein 2 to inner margin. Hindwing: the line just beyond middle to inner margin above anal angle, benzo brown, double filled in with light buff. Wings below pale drab grey with a few black scales; outer line fine, lunular, fuscous, outcurved, subterminal on hindwing; a fine white line on discocellular of forewing. Expanse: 35 mm. French Guiana. A smaller specimen, a female, expanse 32 mm, from São Paulo de Olivença, Amazons, has the line on both wings single. Without more material I do not like to consider it distinct.

rotundula. **D. rotundula** Dogn. *Male*: Body avellaneous; anal hairs with dark tips. Forewing light wood brown with a few black scales at base and along inner margin; traces of a slightly darker wavy antemedial line; a black streak on discocellular outwardly edged with white; outer line buckthorn brown, outbent and wavy on costa with a small black spot, angled below vein 8 and inbent, straight to inner margin. Hindwing buffy brown; a fuscous line on upper discocellular; postmedial line straight; cilia on both wings snuff brown tipped with white on interspaces. Forewing below to line dull cinnamon; postmedial line fine, black on costa, forming two lunules, not angled, sinuous, fine, benzo brown to inner margin; terminal space paler, light buff at apex and towards tornus. Hindwing below light buffish brown with scattered black scales; a very faint and fine outcurved postmedial line. Expanse: 33 mm. Monte Tolima, Colombia. Genitalia as in *Druentia*. The termen of hindwing well crenulate.

laxa. **D. laxa** Dogn. (88 c). *Male*: Head and collar and base of abdomen light vinaceous fawn, thorax and terminal half of abdomen tiller buff, all irrorated with black scales; anal hairs tipped with fuscous. Wings tiller buff largely suffused with pinkish buff, and irrorated with black; line fine, cinnamon buff; cilia buffy brown tipped with white. Forewing: a medial dark point on costa; two hyaline spots at discocellular, oblique and dark edged; line from a black point on costa, oblique and excurved, angled at vein 7, below vein 6 better defined. Hindwing: line postmedial; termen narrowly suffused with orange cinnamon. Wings below paler, the line more outcurved, very fine and crenulate, on hindwing subterminal. Expanse: 30 mm. Argentina.

narila. **D. narila** Dogn. *Male*: Body and wings buffy brown tinged with olivaceous. Forewing: costal edge, a slight terminal suffusion at middle, and base of cilia clay colour; an oblique black spot on discocellular; line olivaceous brown outwardly edged with white, extending to termen between veins 4 and 3, excurved

from costa with a black spot above vein 8, rounded below vein 8 near termen, and slightly incurved to inner margin; some scattered chestnut brown scales. Hindwing: line postmedial slightly outcurved; termen more broadly and uniformly dark. Forewing below to line clay colour, the line darker followed by white to termen between veins 8 and 10; discal spot black outwardly edged with white. Hindwing below largely white suffused to line with greyish; line very faintly indicated; termen narrowly suffused with cinnamon; a black spot on discocellular. Expanse: 29 mm. Monte Socorro, Columbia.

D. corana *sp. n.* (88 c). *Male*: Body and wings as in *narita*. Forewing with the costal edge cinnamon brown, becoming mars brown between line and apex. Hindwing: the line postmedial, straight from costa to inner margin near anal angle. Forewing below as in *narita*. Hindwing below whitish with a few scattered fuscous scales; medial space slightly suffused with cinnamon drab; a short black streak on discocellular; line almost subterminal, outcurved, fine, faintly lunular, interrupted by veins buckthorn brown; termen rather broadly buckthorn brown; cilia dresden brown with a pale line at base, the tips white. Expanse: 33 mm. Paso del Quindiu, Colombia. Type in Museum Berlin.

D. imperita *Dogn.* (88 c). *Male*: Similar to *corana*. Forewing: the line acutely angled at vein 8, not rounded as in *corana* and *narita*; a fine black streak on discocellular outwardly edged with white as in *alsa*. Hindwing: the line postmedial, fine, mikado brown, outwardly edged with pale vinaceous fawn, reaching inner margin near anal angle. Forewing below similar to *corana*, but the line rounded below vein 8 and less produced than in that species, slightly inbent, straight to inner margin. Hindwing below pinkish buff, the termen suffused with cinnamon; a few scattered black scales; line postmedial, fine, cinnamon, vertical from costa to vein 6, slightly outcurved, straight from vein 4 and mottled with bistre to inner margin near anal angle; cilia snuff brown tipped with white. Expanse: 35 mm. Santo Domingo, Carabaya, Peru.

D. alsa *Schs.* (88 c). *Male*: Body and wings cinnamon buff, slightly suffused with pinkish cinnamon and some scattered fuscous scales. Wings: the line clay colour outwardly edged with white, the cilia darker tipped with white. Forewing: costal edge cinnamon; a light vinaceous fawn shade along costal margin; a black streak on discocellular faintly edged with whitish; line excurved and outbent with a black spot on it above vein 8, angled near termen and inbent to inner margin at two-thirds from base. Hindwing: a faint subbasal line; line postmedial to inner margin a little above anal angle. Forewing below to line pinkish cinnamon; discal spot somewhat larger; line faint, sinuous; some whitish at apex and terminally above vein 1. Hindwing below light pinkish cinnamon, towards anal angle pale pinkish buff; faint traces of a macular subterminal line. Expanse: 36 mm. Turrialba, Costa-Rica; Monte Tolima, Colombia.

D. dericca *sp. n.* *Male*: Allied to *alsa*, very similar in colour, and the line the same colour and shape. Forewing: costal margin at base and beyond line white, the costal edge cinnamon; an antemedial inbent cinnamon shade; line with the black spot above vein 8, and edged with black where outangled; black discal spot round and larger than in allied species. Hindwing: a subbasal cinnamon line; a black point at discocellular; line straight, postmedial, inwardly darker shaded than in *alsa*. Forewing below to line orange cinnamon; line fuscous outcurved across vein 7, then sinuous, cut throughout by veins; pinkish cinnamon suffusions at tornus and between veins 4 and 8, the termen otherwise whitish; a black streak at discocellular outwardly edged with white. Hindwing below light pinkish cinnamon on costal half and termen; a small black spot at discocellular; line postmedial, black, macular from vein 8 to vein 6, then outcurved, very faint, crenulate, pinkish cinnamon, defined by the whitish space from cell to line and inner margin; a few scattered fuscous scales on both wings. Expanse: 30 mm. Agualani, Peru.

4. Genus: **Bedosia** *gen. nov.*

Replaces in the *Lacosominae* *Cicinnus* of the *Mimalloninae*. Frenulum present. Antenna bipectinate, short on terminal third. Forewing acute, only slightly produced. Some species with the wing broader than in others, the tornus usually oblique and wavy, the outer margin of hindwing usually crenulate. If the frenulum had not been used to separate the two subfamilies the following species could all have been placed under *Cicinnus*.

Type: *B. fraterna* *Schs.*

B. fraterna *Schs.* *Male*: Head and thorax pale pinkish buff mottled with tawny olive scales, the abdomen with similar fine segmental lines. Wings whitish at base mottled with tawny olive, otherwise pale drab mottled thickly with drab. Forewing: antemedial line fine, tawny olive shortly outcurved on costa, slightly curved and inbent from subcostal to inner margin; hyaline spot at discocellular narrow in front expanding at vein 4; outer line sayal brown, oblique from costa, angled just below vein 7 and inbent; a dark line from angle to apex; below angle the line is inwardly edged with light buff; a hair brown line from vein 4, oblique to tornus; costal edge cinnamon; termen narrowly and cilia from apex to vein 3 snuff brown, the cilia tipped with golden buff.

Hindwing: the line as on forewing, postmedial, straight to inner margin. Forewing below very similar; no antemedial line. Hindwing below: the line fine, tawny olive, subterminal, slightly excurved and outbent, well outcurved from vein 5 to vein 2, then slightly upcurved to inner margin. Expanse: 57 mm. French Guiana; Ponte Nova, Amazons.

itamaraty.

B. itamaraty Foett. (88 d). *Male*: Body and wings pale pinkish buff. Collar tipped behind with xanthine orange. Tegulae with some flesh ocher irrorations. Abdomen: a dorsal xanthine orange line and some finer segmental lines. Forewing: base with some flesh ocher irrorations; costal edge, lines, cilia, except at base of inner margin and a streak on fold below cell xanthine orange; antemedial line very fine, vertical, not reaching inner margin; an oblique hyaline spot at discocellular expanding to vein 4; outer line very oblique, angled at vein 7 with a dark line from angle to apex, expanding somewhat to inner margin and inwardly pale edged; a fine dark line from vein 5 to tornus; terminal space somewhat suffused with light drab. Hindwing: the outer line continued to inner margin below middle; outer half of wing irrorated with drab. Wings below whiter irrorated with drab. Forewing: no antemedial line, the outer line as above; a dark line from vein 3 to tornus. Hindwing: the line fine, postmedial, almost vertical to vein 4, rounded and incurved to inner margin. The museum specimen does not show the hair brown spot at apex, as figured in the Rev. Mus. Paul. Expanse: 60 mm. Joinville and São Paulo, Brazil. The hindwing is evenly rounded.

balca.

B. balca Schs. *Male*: Body and wings pinkish buff. Abdomen with a dorsal avellaneous line. Forewing: costal edge, a fine line on submedian fold, an oblique line from costa to discocellular, and outer line pale orange cinnamon; outer line as in *itamaraty*, but finer and not pale edged inwardly; the angle almost touching termen, the line from it to apex black; from line at vein 4 some black suffusions parallel with line forming a black spot above inner margin, other black scaling diverging at vein 3 to tornus. Hindwing with the line as on forewing followed by a black spot on vein 4; a few dark scales on terminal space. Wings below paler with a few black irrorations. Forewing as above, the hyaline spot outwardly edged with fuscous; line very fine, postmedial more evenly curved than in *itamaraty*. Expanse: 55 mm. Omai, British Guiana. The tornus of forewing and termen of hindwing crenulate.

strigifera.

B. strigifera Fldr. (88 d). *Male*: Wing shape of *itamaraty*, the anal angle of hindwing somewhat acute. Head, collar, thorax and wings pinkish buff; abdomen pale pinkish cinnamon. Wings with some slight brownish scales on terminal space, the lines buckthorn brown; cilia tawny olive tipped with pinkish buff. Forewing: antemedial line very faint, slightly outcurved; hyaline spot at discocellular narrow in front, expanding behind; outer line narrow, oblique from costa, angled below vein 7 with a fine line from angle to termen at apex, below angle inbent to inner margin; a fine dark line from vein 4 oblique to tornus. Hindwing: the line postmedial, straight; a brownish line from vein 4 to termen below vein 2. Wings below similar. Hindwing: a small dark streak on discocellular; the line postmedial, slightly inbent to vein 4, rounded and sinuous to inner margin. Expanse: male, 56 mm; female, 63 mm. Colombia. The identification is possibly wrong, as I do not know what direction the line on under side of hindwing follows. Felder's figure, a female, shows also a heavy outcurved antemedial line.

turgidus.

B. turgidus Schs. (88 d). *Male*: Body and wings pinkish buff thickly irrorated with sayal brown. Forewing: a wavy antemedial cinnamon line, slightly outbent, the costal edge buckthorn brown; an oblique hyaline spot at discocellular expanding behind; the line fine from costa, cinnamon buff, very oblique, sharply angled at vein 6 with a hair brown line from angle to termen near apex, from angle inbent, thicker, cinnamon, inwardly edged with light ochraceous buff; veins terminally warm buff; an interrupted hair brown streak from line at vein 4 to termen at tornus. Hindwing: line as on forewing medial on costa, postmedial at inner margin; a fine hair brown line beyond medial from vein 5 to vein 2 before termen; cilia on both wings tawny olive tipped with white. Wings below with fewer dark scales; line fine tawny olive, otherwise as above. Hindwing below: the line very fine, postmedial, outbent and curved, then inbent to inner margin. Expanse: male, 49 mm; female, 60 mm. Muzo, Colombia; Sixola River, Costa Rica. Tornus of forewing, and termen of hindwing crenulate.

ligina.

B. ligina Schs. *Male*: Body and wings pinkish buff; abdomen and base of forewing with a few dark scales. Forewing: lines and discal spot as in *turgidus*, the outer line finer, fawn colour, more excurved from costa, the angle more remote from termen; small hair brown spots beyond line below veins 4 and 3. Hindwing with some scattered dark scales; line as on forewing just beyond middle, the space beyond to termen suffused with avellaneous; a small dark spot between veins 4 and 3; cilia orange cinnamon tipped with white. Wings below paler; forewing as above, the line paler and finer; line on hindwing very faint in type, shaped as in *turgidus*. Termen crenulate. Expanse: male, 40 mm; female, 50 mm. Cachi, Juan Viñas, Costa Rica.

gilia.

B. gilia Schs. *Male*: Body and wings to line light ochraceous buff without any dark scales; terminal space olivaceous avellaneous; line buffy, olive brown inwardly edged from angle of forewing with warm buff. Forewing: a hyaline spot as in *ligina*, but slightly larger; outer line angled well before termen. Hindwing: line

from just beyond middle of costa to below middle of inner margin. Forewing below: base obliquely to line and inner margin buff white, otherwise ochraceous buff; line as above; a large hair brown patch from vein 3 to inner margin beyond line. Hindwing below: line fine, almost subterminal, excurved slightly from costa, bulging from vein 5 to vein 2 and inbent to inner margin; the darker terminal shading extending within line. Expanse: male, 42 mm; female, 52 mm. French Guiana. Same shape as *turgidus* and *ligina* with termen slightly crenulate.

B. batesii Newm. (88 d). *Male*: Body and wings light fawn colour, the lines fine, darker; some scattered black scales on wings except on termen. Forewing: antemedial line very faint; discal spot small, faintly outlined; outer line oblique from costa, angled and inbent below vein 7; cilia orange cinnamon. Hindwing: the line medial; cilia whitish at tips. Expanse: 40 mm. Santarem, Amazons. A female from the Berlin Museum is figured.

B. trailii Btlr. (= *venata* Dogn.). *Male*: Body and wings light pinkish cinnamon thickly irrorated with buckthorn brown; abdomen with whitish segmental lines. Forewing: an oblique hyaline spot at discocellular, dark edged and crossed by vein 5; postmedial line tawny olive outwardly edged with white, oblique from costa and sharply angled below vein 7, then straight, inbent to inner margin; veins on terminal area finely streaked with pinkish buff and pale tawny olive; cilia tawny olive tipped with white on interspaces; the termen slightly crenulate below vein 3. Hindwing: the line as on forewing, straight, postmedial; veins beyond line streaked with tawny olive, paler than the line; cilia as on forewing; termen slightly crenulate. Wings below as above. Expanse: male, 39 mm; female, 46 mm. The Guianas; Ponte Nova, Amazons. The apex of forewing is acute, the termen inbent, straight; the anal angle of hindwing slightly produced. The female has the outer margins rounded.

5. Genus: **Lacosoma** Grt.

Male: Frenulum present. Antenna bipectinate. Palpi slender, short, hairy. Legs moderately hairy; hind tibiae with short terminal spurs. Forewing: apex falcate; termen excurved below apex, inbent below vein 3, partly crenulate; vein 2 from middle of cell; 3 near angle; 4 lower angle; 5 middle of discocellular; 6 upper angle; 7 and 8 stalked; 9 and 11 from cell, 10 as a short spur from 9. Hindwing: costa convex; termen crenulate, inbent below vein 4; vein 2 from beyond middle of cell; 3 before lower angle; 4 from angle; 5 middle of discocellular; 6 upper angle; 7 from cell before angle.

Type: *L. chiridota* Grt.

L. vulfreda sp. n. (88 d). *Male*: Head light salmon orange. Thorax and abdomen light russet vinaceous, the latter dorsally suffused with light salmon orange on terminal half. Wings light greyish vinaceous with reddish suffusions near base below cell, and some scattered black scales. Forewing: a black streak and some white scales at discocellular; costal edge orange cinnamon; a faint vinaceous drab postmedial line almost vertical followed by a mineral red shade expanding from vein 6 to vein 2 and tornus. Hindwing: a faint and fine postmedial vinaceous drab line; termen broadly mineral red; cilia tipped with white, on forewing with pale vinaceous. Forewing below vinaceous rufous from base to three-fourths with some black scales; terminal space mostly light greyish vinaceous. Hindwing below almost as above, the black scales more numerous, the termen more narrowly red. Expanse: 32 mm. Bella Vista, West Colombia. Type in Collection Niepelt.

L. syrinx Drc. (88 d). *Male*: Head and collar hair brown. Thorax and abdomen light drab. Forewing hair brown, markings light drab; a spot at base below cell; an antemedial wavy line, thicker on costa and inner margin; an oval line at discocellular; a medial spot below vein 2; a postmedial line of lunules; apical space broadly on costa narrowing along termen to vein 2, light drab suffused with drab at apex. Hindwing: base salmon buff with a large hair brown patch from cell to inner margin; medial line broad, wavy from costa to vein 3, then inbent to middle of inner margin, followed by a broad light drab shade cut by a hair brown line diverging at vein 3, the outer part reaching inner margin near anal angle; termen broadly hair brown; cilia tipped with light buff on interspaces. Wings below mostly chaetura drab. Forewing with a fine whitish line at discocellular; outer line white on costa; termen irregularly light drab from vein 8 to vein 2. Hindwing: base suffused with carot brown; an antemedial ochraceous salmon fascia from within cell to inner margin, some white on costa above it; a black spot on discocellular; a subterminal faint pale smoky grey line. Expanse: male, 39 mm. Costa Rica; Venezuela.

L. briasia sp. n. (88 c). *Male*: Allied to *syrinx*. Body and wings darker, the marking less prominent. Underside of hindwing without the ochraceous salmon fascia; the spot on discocellular light drab grey. Expanse: 35 mm. Buena Vista, Colombia; St. Jean, French Guiana; Rio Tapajos, Amazons.

L. otalla Schs. (88 d). *Male*: Head, collar partly, throat, and fore legs bittersweet pink. Thorax white. Abdomen pale cinnamon pink or suffused with pale pinkish buff. Forewing: base and inner margin to outer line white; costal edge bittersweet pink, costa below edge white; medial area roseate with an oblique black line

on discocellular; outer line very fine diffuse, dark from a fuscous point on costa, outangled below vein 8 and slightly sinuous; terminal space ecru drab with faint pinkish suffusion at tornus. Hindwing: basal half whitish limited by a fine dark postmedial line, the termen ecru drab mostly suffused with pinkish; a few scattered black scales on both wings. Forewing below with medial area bittersweet pink; both wings with black lines on discocellulars. Expanse: 31 mm. St. Laurent Maroni, French Guiana.

ludolpha. **L. ludolpha** *sp. n.* (88 c). *Male*: Differs from *otalla* in the genitalia and larger size. Forewing: the postmedial line not outangled, but slightly outcurved, almost vertical. Hindwing: termen without pinkish suffusions. Wings below with the line better defined. Expanse: 34 mm. San Esteban Valley, Venezuela.

raydela. **L. raydela** *sp. n.* (88 e). *Male*: Head and front of collar bittersweet orange, body otherwise white, the abdomen dorsally suffused with light drab. Forewing: base whitish limited by a fine vertical vinaceous fawn line; medial area pinkish cinnamon: a thick white streak on discocellular mottled with black scales inwardly; a fine dark, but faint, postmedial line, minutely wavy, incurved opposite cell, followed by a similar faint line from below vein 8, expanding into a vinaceous fawn shade from vein 4 to tornus; terminal space from vein 3 to costa pale vinaceous fawn, except narrowly on termen from vein 8 to vein 4 which is vinaceous fawn; cilia clay colour tipped with white and pinkish. Hindwing tiller buff; a faint vinaceous fawn, outcurved, postmedial line; some vinaceous fawn on termen from apex to vein 4; cilia as on forewing; both wings with a few black scales. Forewing below to line, except on inner margin light coral red; line fine, sinuous, drab defined by pale drab grey; termen vinaceous fawn. Hindwing below whitish; the line postmedial, outcurved; termen broadly vinaceous fawn; some black scales on discocellular; both wings irrorated with black. Expanse: male, 30—34 mm; female, 38 mm. Cayuga, Guatemala; Juan Viñas, Costa Rica. Type in the National Museum.

diederica. **L. diderica** *sp. n.* *Male*: Head and front of collar bittersweet orange; collar behind and thorax whitish; abdomen tiller buff dorsally suffused with vinaceous buff. Forewing: costal edge cinnamon red; base whitish limited by an antemedial fawn colour line outcurved below cell; medial area vinaceous cinnamon: a black spot at discocellular; postmedial line red at costa then fine, black, wavy and lunular, vertical; terminal space vinaceous fawn with an incurved pale greyish vinaceous shade from apex to termen at vein 3; cilia sayal brown tipped with white. Hindwing to line above median light vinaceous cinnamon; inner margin broadly to near termen pale vinaceous fawn; a whitish spot with black scales on discocellular; line fine, postmedial, slightly curved, lunular; termen broadly amber brown. Both wings with a few black scales above and below. Forewing below, except on inner margin light coral red; line faint, slightly outcurved, well marked and black at inner margin; termen as above. Hindwing below paler, the termen suffused with vinaceous cinnamon. Expanse: male, 27 to 33 mm. Amazons, Bolivia, Paraguay.

philastris. **L. philastris** *sp. n.* (88 e). *Male*: Wings shaped as in *cantia*. Body and wings white with scattered black scales. Frons pinkish buff. Forewing: costal edge pinkish cinnamon; a black spot on discocellular; a faint drab postmedial line, better defined on costa and outbent, then sinuous and inbent, followed by a drab shade outbent from vein 4 to tornus; cilia tawny olive tipped with white. Hindwing: the line only perceptible near inner margin. Forewing below: cell and beyond above vein 6 to line suffused with pinkish cinnamon. Hindwing below with a faint spot on discocellular; the line postmedial faintly traceable throughout; termen to near anal angle suffused with drab. Expanse: 32 mm. Amazons above Teffé.

turnina. **L. turnina** *sp. n.* *Male*: Forewing bluntly produced, excised, inbent from vein 3 and crenulate. Hindwing with termen crenulate. Body vinaceous drab mottled with cinnamon brown. Frons and palpi tawny. Wings pale brownish drab; cilia brownish drab tipped with white on interspaces. Forewing: an antemedial wavy russet shade; a black spot on discocellular; costal edge cinnamon brown; postmedial line vertical, sinuous, deep brownish drab followed by a similar parallel shade not reaching costa; termen narrowly deep brownish drab from above vein 7 to vein 3. Hindwing: a faint dark discal point; postmedial line faintly indicated; termen rather broadly cinnamon brown. Wings below rather paler, the forewing with base except on inner margin, cell and beyond cell above vein 5 to postmedial line suffused with tawny. Hindwing below as above. Expanse: 24 mm. São Paulo de Olivença, Amazons.

julietta. **L. julietta** Dyar. *Male*: Darker than *otalla*. Forewing with costal edge cinnamon, the wing to outer line vinaceous tawny; outer line more sinuous, the termen darker. Hindwing uniformly drab grey with very faint reddish suffusions; the black scales on wings more numerous. Hindwing below without a black streak on discocellular, the cell pinkish. Expanse: 27 mm. Misantla, Mexico. Vein 9 present in type. Termen of hindwing very faintly crenulate.

L. ladema Dogn. *Male*: Head, throat, and forelegs pinkish cinnamon. Body pale cinnamon pink, *ladema*. Wings with a few black scales, and black lines on discocellulars. Forewing: base, inner margin medially and costa, except edge, pale pinkish cinnamon, the base limited by a cinnamon buff vertical line; costal edge and median area cinnamon buff; discal line outwardly edged with silvery white; outer line very fine and faint, slightly outcurved on costa; an incurved lilaceous shade from apex to termen at vein 3, termen otherwise cinnamon buff. Hindwing pale cinnamon pink; an antemedial shade and termen cinnamon buff, broadly at apex, narrowing to anal angle; a faint medial dark curved line. Forewing below ochraceous orange; discal line entirely black; outer line heavier, the lilaceous shade from apex narrower, the termen otherwise cinnamon buff. Hindwing below more distinctly marked, the colour as on upper side. Expanse: 33 mm. Muzo, Colombia; Cachi, Costa Rica. Termen of wings slightly crenulate.

L. lygia Schs. *Male*: Head, throat, and forelegs pinkish cinnamon. Collar and abdomen pale vinaceous *lygia*. fawn, the thorax white. Wings pale ecru drab with scattered black scales. Forewing: costal edge and cilia pinkish cinnamon, the latter tipped with white; a faint black line on discocellular; a fine dark antemedial line, slightly outcurved; medial area faintly suffused with vinaceous pink; outer line very faint, not outangled below costa; faint darker suffusions from tornus to vein 4. Hindwing: termen suffused with vinaceous fawn. Wings below with black scales more numerous; medial area of forewing and termen of hindwing vinaceous cinnamon. Wings finely crenulate. Expanse: 35 mm. Sixola River, Costa Rica; São Paulo de Olivença, Amazons.

L. cantia sp. n. *Male*: Wings shaped as in *turnina*, but less deeply crenulate. Head, palpi, and forelegs *cantia*. light coral red. Body and wings pale drab grey, almost white with a few black scales; abdomen dorsally suffused with light cinnamon drab. Forewing: costal edge cadmium yellow; an antemedial cinnamon drab line from subcostal to inner margin, slightly outbent, followed by a light vinaceous fawn shade; a few black and white scales on discocellular; postmedial line narrow, hair brown, slightly outbent on costa, vertical, finely wavy to inner margin, followed by a cinnamon shade on inner margin to tornus, above vein 2 to vein 4 by a wavy hair brown shade; termen towards apex narrowly cinnamon drab; cilia clay colour tipped with white on interspaces. Hindwing with some scattered black scales; traces of a faint outcurved postmedial line; cilia as on forewing tipped with white only towards anal angle. Forewing below suffused with tawny to postmedial line which is more heavily marked. Hindwing below with postmedial line distinct from vein 3 to inner margin; termen from apex to vein 3 tawny olive. Expanse: 26 mm. São Paulo de Olivença, Amazons.

L. ? violacea Sepp. This species, unknown to me except by the figure in Sepp, is doubtfully placed *violacea*. here. It is deep violet plumbeous irrorated with black, the outer margin glaucous grey with a dark terminal line; traces of an antemedial and postmedial line; a dark spot on discocellular. The hindwing is without the pale outer margin and shows a postmedial line inbent to middle of inner margin. The wings are apparently crenulate, not excised below apex of forewing. Expanse: 45 mm. Surinam.

L. perplexa Schs. *Male*: Head pinkish buff. Collar and thorax pale cinnamon pink, the tegulae with *perplexa*. some black scales. Abdomen pale pinkish buff. Wings drab grey irrorated with black. Forewing: outer half of cell and a patch beyond between veins 5 and 10 light coral red; a black streak on discocellular; outer line drab, slightly incurved below vein 5; termen with some darker suffusions. Hindwing: termen narrowly and a broad line from beyond middle of costa to middle of inner margin cinnamon buff. Wings below similar with colouring more intense. Expanse: 29 mm. Quirigua, Guatemala. Outer margin of forewing sinuous, of hindwing rounded.

L. rosea Dogn. *Male*: Body and wings pale vinaceous fawn, the basal half of wings with scattered *rosea*. black scales; head and front of collar light pinkish cinnamon. Forewing: costal edge light pinkish cinnamon; traces of a pinkish antemedial line; a black line on discocellular edged with whitish; outer line fine, black, wavy, between veins 4 and 2 lunular, followed from vein 4 to inner margin by a faint vinaceous fawn shade. Hindwing: a dark postmedial outcurved line; apex suffused with vinaceous fawn; a faint dark line on discocellular. Forewing below light coral red from base to outer line, the inner margin and termen pale vinaceous fawn, partly suffused along termen with vinaceous fawn. Hindwing below as above. Expanse: 32 mm. Popayan, Colombia. Forewing with termen sinuous, crenulate below vein 3. Hindwing very faintly crenulate at apex, the anal angle acute.

L. arizonicum Dyar. *Male*: Forewing not falcate, termen slightly sinuous and crenulate at tornus. *arizonicum*. Hindwing faintly crenulate. Body pale pinkish buff, the head suffused with light vinaceous cinnamon. Wings light pinkish cinnamon. Forewing: a greyish line on discocellular outwardly edged with white; postmedial line very fine, wood brown, slightly curved on costa. Hindwing slightly suffused with pinkish cinnamon, the line very fine, slightly outcurved, medial. Wings below slightly darker with some black irrorations; fine black lines on discocellulars of both wings. Expanse: 29 mm. Arizona, United States of America.

- aurora.* **L. aurora** Dogn. *Male*: Head, thorax, and forelegs flame scarlet. Thorax pale flesh colour; abdomen dorsally suffused with rufous. Wings flesh colour, the terminal areas rufous; a few scattered black scales. Forewing: a fine black streak on discocellular; outer line merely indicated by different colour of terminal area; a lilacine white incurved shade from apex between veins 2 and 3. Hindwing: a faint medial line, straight to below middle of inner margin; the outer area somewhat paler, adjoining line from vein 4 to inner margin. Forewing below light coral red, except the incurved shade from apex. Expanse: 31 mm. Muzo, Colombia.
- valera.* **L. valera** sp. n. (88 e). *Male*: Head, throat, forelegs, and front of collar purplish red. Thorax and abdomen maize yellow, suffused especially on abdomen with purplish red. Forewing maize yellow to outer line; terminal space purplish red; some reddish scaling at base; a fine dark line on discocellular narrowly edged with reddish; outer line inbent, wavy, slightly darker than termen; cilia black tipped with white. Hindwing maize yellow to outer line except the reddish streak along inner margin; a straight dark medial line to inner margin above anal angle; outer area and cilia as on forewing; some white and black scaling on inner margin below the line. Underside as above. Expanse: 32 mm. Valera, Venezuela. Forewing sinuous and crenulate at tornus, the hindwing slightly crenulate. Type in the U.S. National-Museum.
- asea.* **L. asea** sp. n. *Male*: Palpi, throat and frons ferruginous. Thorax and abdomen avellaneous. Wings from base to line ochraceous tawny, terminal space cinnamon brown, the cilia tipped with light buff. Forewing: a fine straight antemedial line, somewhat darker, and slightly outbent; a drab spot on discocellular; outer line prout's brown, fine, outcurved on costa and almost vertical. Hindwing: the line postmedial, prout's brown, slightly curved. Forewing below ferruginous from base to outer line, the discal line black. Hindwing below as above, but with a fine black line on discocellular. Expanse: male, 30 mm. Pacho, Colombia. Forewing sinuous and crenulate from vein 3 to tornus. Hindwing crenulate.
- oyapoca.* **L. oyapoca** sp. n. (88 e). *Male*: Forewing with apex produced, not acute, termen faintly crenulate from vein 3 to tornus. Hindwing with termen rounded appearing crenulate owing to markings on cilia. Body tawny olive. Wings to line vinaceous buff suffused with light tawny olive. Forewing: a dark point on discocellular; costal edge rufous; outer line remote, dark, threadlike, slightly outbent on costa and then vertical; termen broadly tawny olive from above vein 8 to inner margin; cilia brownish olive tipped with white on interspaces and with light coral red at veins. Hindwing with line remote, faint, threadlike, from vein 2 upbent to inner margin, broad, hair brown; termen broadly tawny olive, the cilia as on forewing. Wings below isabella colour with a few black scales; the line better defined; black points on discocellulars of upper and lower wing. Expanse: 32 mm. Oyapock River, French Guiana. Type in Carnegie Museum, Pittsburgh; a paratype in the National Museum.
- chiridota.* **L. chiridota** Grt. (88 e). *Male*: Body and wings sayal brown with some scattered black scales. Forewing: a black spot on discocellular; outer line fine, snuff brown, outcurved on costa and slightly sinuous to inner margin; apex rounded and well produced. Hindwing: a faint spot on discocellular; the line medial, darker; cilia of forewing black at apex, tipped with white at excisions. Underside with line of forewing and discal spot more heavily marked. Female more deeply excised below apex. Body and wings ochraceous buff, the wings partly suffused with ochraceous orange; black streaks on discocellulars; lines broader than in male. Wings below light ochraceous buff marked as above. Expanse: male, 25 mm; female, 30 mm. Atlantic States.
- zonoma.* **L. zonoma** sp. n. *Female*: Allied to *chiridota*, the shape of wings similar. Body and wings intermediate between pinkish cinnamon and clay colour as given in Ridgeway, the line fine, slightly darker. Forewing: a drab line on discocellular outwardly edged with pale smoke grey; the line sinuous. Hindwing: a faint drab line on discocellular. Wings below paler with a few black scales; the line and discal streaks fine but more distinct, the line on hindwing postmedially inbent from vein 3 to inner margin. Expanse: 31 mm. Orizaba, Jalapa, Mexico.
- medalla.* **L. medalla** Dyar (88 e). *Male*: Wing shape as in *zonoma*, slightly broader. Body and wings vinaceous avellaneous, in the female light vinaceous cinnamon with very few darker scales; cilia fawn colour tipped with white on interspaces. Forewing: a faint darker, wavy, antemedial line; a dark oblique line on discocellular; a fine hair brown postmedial line almost straight and vertical, passing rather close to cell. Hindwing: the line medial, slightly curved. Wings below with markings more distinct. Forewing: no antemedial line, the postmedial outcurved and sinuous. Hindwing: the line postmedial; a fine line on discocellular. Expanse: 31 mm. Zacualpan, Mexico; a female, the type, from Cuernavaca, Mexico.
- lola.* **L. lola** Schs. *Male*: Forewing acute faintly produced, crenulate at tornus and at apex of hindwing. Body and wings drab grey with a few scattered dark scales, cilia drab. Forewing: a fine fuscous line on discocellular outwardly edged by a whitish or small hyaline spot; outer line fine, fuscous, outangled at vein 8,

with a small black spot on it between veins 8 and 9, below 8 inbent to inner margin. Hindwing: the line straight from close beyond middle to inner margin near angle. Wings below without the line on hindwing. Expanse: 25—30 mm. French Guiana and Amazons.

L. schausi Dogn. (= *rosea* Schs. preocc.). *Male*: Forewing produced at apex, slightly incurved and inbent to vein 2, then inbent, crenulate. Hindwing broad and narrow, the apex rounded, very faintly crenulate to anal angle. Body and wings light pinkish cinnamon; head and collar buff pink; a very few black scales; cilia light brownish olive tipped with flesh pink. Forewing: costa cinnamon rufous; a very faint, fine, outer line, almost imperceptible; termen slightly darker; a few greyish and white scales on discocellular. Hindwing: outer half suffused with cinnamon buff. Wings below cinnamon buff, the base and costa of hindwing light pinkish cinnamon. Expanse: 32 mm. St. Jean Maroni, French Guiana.

L. bigodia sp. n. *Male*: Forewing bluntly produced, excised to vein 3, slightly inbent and crenulate. Hindwing rounded, crenulate to vein 3, then inbent to angle. Frons buffy brown. Body white. Wings brownish avellaneous with a few scattered black scales. Forewing: a black and white line on discocellular; the line subterminal, fuscous, crenulate; termen above vein 6 to apex suffused with drab grey; cilia fuscous tipped with white. Hindwings somewhat paler, the base and inner margin whitish; a black spot on discocellular; a subterminal wavy fuscous line, only distinct from costa to vein 5 followed by some light grey scaling; cilia fuscous mottled with cinnamon brown. Wings below pale yellow orange with a few black scales; discal spots larger; the line on forewing indistinct. Expanse: 20 mm. Amazons above Teffé.

L. valva Schs. *Male*: Body and wings fawn color. Forewing: traces of a fine paler antemedial line; a pale ochraceous buff line or spot on discocellular; outer line light ochraceous buff outangled between veins 7 and 8 and inbent to beyond middle of inner margin, inwardly edged with dresden brown. Hindwing: the line postmedial on costa, straight to middle of inner margin. Wings below light cinnamon drab. Forewing: the discal spot inwardly edged by a fine fuscous line; outer line outcurved, sinuous to vein 4, outangled at vein 3, and incurved to inner margin; termen below apex to vein 3 shaded with fuscous. Hindwing: the line from costa slightly incurved and outbent to vein 4, downbent to vein 3 and upcurved to inner margin below middle. Expanse: male, 28 mm; female, 31 mm. French Guiana; Las Quiguas, Venezuela.

6. Genus: **Eadmuna** gen. n.

Antenna bipectinate, short at tip. Frenulum present. Palpi upturned, fringed below, apart between first and second joint; third joint short, smooth. Forewing: costa convex towards apex; termen vertical, faintly sinuous; tornus not rounded; vein 2 well before middle of cell; 3 before angle; 4 from angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 shortly stalked. Hindwing: termen rounded; anal angle produced, acute; vein 2 just beyond middle of cell; 3 near angle; 4 from angle; 5 from middle of discocellular; 6 from upper angle; 7 slightly before angle. Genitalia allied to those of *Psychocampa*.

Type: *E. esperans* Schs.

E. esperans Schs. (88 e). *Male*: Body and wings ecru drab. Forewing: costal edge wood brown; traces of a fine antemedial brownish line; a semihyaline buffish B-shaped spot at discocellular edged with cinnamon brown; outer line from a small chestnut brown spot at costa, then very fine and faint, wood brown, slightly outcurved beyond cell, crenulate wavy, followed by small double lunules between veins 4 and 6; termen shaded with glossy wood brown. Hindwing paler at base; line postmedial, outcurved, faint to vein 6, then dentate crenulate more heavily marked; termen wood brown extending to before line; some scattered benzo brown scales, and a few others, fan-shaped white tipped with benzo brown. Wings below with the line almost subterminal, more distinct, lunular interrupted by veins. The anal angle of hindwing is prolonged. Expanse: 35 mm. Espiritu Santo, Brazil. A specimen from the Mana River, French Guiana has the line on hindwing inbent to middle of inner margin.

7. Genus: **Tolypida** gen. n.

Male: Antenna bipectinate, the pectinations diminishing gradually to tips. Frenulum present. Palpi porrect. Tibiae with long fine hairs. Forewing: apex rounded; termen straight, rounded at tornus; vein 2 beyond middle of cell; 3 near 4; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 moderately stalked; 9 and 11 from cell. Hindwing: termen rounded; anal angle slightly prolonged and rounded; vein 2 close to 3 from near end of cell; 4 from lower angle; 5 from middle of discocellular; 6 and 7 from upper angle. The genitalia differ from any other genus.

Type: *T. amaryllis* Schs.

amaryllis.

T. amaryllis Schs. (= *alboflava* Dogn.). (86 g). *Male*: Head and collar white, the latter edged in front and behind with amber yellow. Body massicot yellow, with amber yellow transverse lines on abdomen dorsally. Wings amber yellow; cilia tipped with white. Forewing: costa white; an antemedial and a postmedial buffy citrine broad line, edged on either side with white; outer space with the veins broadly wax yellow. Hindwing: antemedial line nearer base, downbent, not edged with white; postmedial line as on forewing, straight to inner margin near anal angle, outer space as on forewing. Forewing below with the line more remote, the veins near termen more broadly dark shaded. Hindwing below with the line visible in transparency. Expanse: 29—32 mm. São Paulo, S.E. Brazil; Dutch Guiana.

8. Genus: **Vanenga** *gen. n.*

Male: Antenna bipectinate diminishing near tips. Frenulum present. Palpi very short, slender, hairy. Forewing: apex rounded; termen very faintly incurved; vein 2 from middle of cell; 3 before angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 stalked. Hindwing: termen rounded; vein 2 beyond middle of cell; 3 before angle; 4 from angle; 5 from middle of discocellular; 6 and 7 from upper angle. Genitalia near those of *Lacosoma*.

Type: *V. mera* Dogn.

mera.

V. mera Dogn. (86 g). *Male*: Body and wings pinkish cinnamon; a few black scales on terminal space; line hair brown outwardly shaded with purplish clay colour, more broadly on hindwing, from apex of forewing to middle of inner margin on hindwing. Forewing: a faint dark line on discocellular. Forewing below to line zinc orange; a black line on discocellular; line hair brown, faint, postmedial, slightly outcurved on costa; terminal space vinaceous cinnamon suffused with olivaceous. Hindwing below to line light pinkish cinnamon, the line medial; terminal space as on forewing. Female differs in having the line on forewing above postmedial, as on under side of male. Expanse; male, 22—32 mm; female, 29 mm. Obidos, Amazons; Blumenau, S.E. Brazil; Paraguay.

9. Genus: **Macessoga** *gen. n.*

Male: Antenna with long bipectinations diminishing slightly at tip. Frenulum present. Forewing broad; apex bluntly acute; termen slightly sinuous; vein 2 from before middle of cell; 3 well before angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 on short stalk. Hindwing: vein 2 from beyond middle of cell; 3 close to angle; 4 from lower angle; 5 from middle of discocellular which is oblique; 6 and 7 from upper angle.

Type: *M. fabia* Drc.

fabia.

M. fabia Drc. (88 f). *Male*: Body above flesh-ocher shaded with rufous. Forewing apricot buff to line; base narrowly and costal margin cream colour; an antemedial ferruginous lunular line from a black point on costa, the lunules filled in with yellowish; a large round cream colour spot on outside of discocellular; outer line from a black point on costa, very fine, dark, oblique to vein 7, angled and inbent to inner margin beyond middle, cinnamon brown, narrow; terminal space mostly cream colour; a small ochraceous tawny shade on termen opposite angle of line and some apricot buff shading beyond line; a terminal line and base of cilia buckthorn brown, tips of cilia white. Hindwing: line postmedial, slightly thicker than on forewing outwardly edged with buff yellow, followed at middle by a broad buckthorn brown shade, partly suffusing with a vinaceous rufous shade along termen; base cream colour edged by a curved ferruginous line; inner margin broadly cream colour, and a large similar patch at apex. Both wings well irrorated with black scales. Wings below largely pale maize yellow irrorated with black scales; the line subterminal, fuscous, deeply dentate and partly crenulate; anterior half of forewing to line tawny, and its discal spot pale maize yellow; termen of hindwing largely tawny. Expanse: male, 45 mm; female, 60 mm. Panama (type in Berlin Museum); Carabaya, Peru; French Guiana.

aelfrida.

M. aelfrida *sp. n.* (88 f). The following three forms probably represent a single species. They are not represented in the National Museum so it is impossible to have genitalia slides made for examination. *Male*: Head and collar light pinkish cinnamon. Thorax, abdomen and wings pinkish buff, all with a few scattered black scales. Forewing: a wavy vertical antemedial cinnamon line from a small black spot on costa; two hyaline spots at discocellular separated by vein 5, inwardly edged with cinnamon, outwardly with black; line fine, fuscous black, outbent from a small black spot at costa, angled at vein 7 and faintly inbent; termen partly suffused with cinnamon. Hindwing: a cinnamon antemedial shade; line as on forewing, postmedial; termen narrowly orange cinnamon. Wings below similar with pinkish cinnamon suffusions in cell of forewing, and on termen of both wings. Forewing: the line visible in transparency, very fine, from vein 6 to vein 2, from

costa thicker, black, excurved, then outcurved and crenulate from vein 7 to vein 2, then vertical to inner margin. Hindwing: postmedial line as above, but very fine and faint, followed by an outcurved crenulate line. Expanse: 26 mm. Passa Quatro, Minas, Brazil. The specimen is somewhat worn, but there are indications of the termen being crenulate. — *hyginia* f. n. (88 f) *Male*: Head and palpi bittersweet pink. Collar light pinkish cinnamon. *hyginia*. Thorax and abdomen vinaceous buff with a few black scales. Wings vinaceous buff: a wavy dentate antemedial vinaceous fawn line; outer line as in *aelfrida*, also the discal spot. Forewing: termen opposite cell and at tornus suffused with cinnamon drab. Hindwing: the line preceded and followed by an irregular buffy brown shade; termen narrowly orange cinnamon. Forewing below: inner margin, apex and termen between veins 2 and 4 pale greyish vinaceous, the wing otherwise pinkish cinnamon; the line outcurved, crenulate from vein 8. Hindwing below pinkish buff suffused with light vinaceous cinnamon; the line postmedial, outcurved, crenulate. The termen of both wings distinctly crenulate. Expanse: 29 mm. Passa Quatro, Brazil. — *hoppia* f. n. (88 f). *hoppia*. *Male*: Differs from *M. aelfrida* Schs. in its larger size and the even termen of both wings. On the forewing veins 7 and 8 are from the cell instead of being stalked, probably not a constant character. Expanse: 32 mm. Rio de Janeiro, Brazil. Type in Collection Hopp.

10. Genus: **Zaphanta** Dyar.

Male: Antenna bipectinate, short beyond middle. Palpi short, upturned. Forewing broad; apex acute; termen straight below apex, angled at vein 3; vein 2 from middle of cell; 3 close to angle; 4 from angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 stalked; 9 and 11 from cell. Hindwing: termen straight from apex to vein 3, angled and usually slightly toothed; vein 2 from middle of cell; 3 and 4 close together; 5 from middle of discocellular; 6 from upper angle; 7 from before end of cell.

Type: *Z. infantilis* Dyar.

Z. infantilis Dyar (= *fraterna* Schs.). (88 f) *Male*: Head and thorax clay colour. Abdomen avellaneous, darker on segments posteriorly. Wings warm buff or ocher yellow; base dark vinaceous drab; a purplish marginal shade; some scattered dark scales. Forewing: costal margin from before middle to apex yellowish white; traces of a postmedial crenulate line; a few outbent fuscous lunules from costa before apex. Wings below maize yellow with a few dark irrorations; base more narrowly pale purplish limited by an inbent wavy and interrupted fuscous black line. Forewing with the lunules from costa subterminal below vein 8, well inset below vein 3. Hindwing: a postmedial fuscous crenulate line, upcurved between veins 4 and 2. Expanse: 22 mm. British and French Guiana; Costa Rica; Guatemala. *infantilis*.

11. Genus: **Menevia** gen. n.

Male: Frenulum highly developed. Antenna bipectinate to tips, diminishing from base. Palpi upturned smoothly scaled with slight fringe below. Legs hairy; hind tibiae with short terminal spurs. Forewing: apex falcate; outer margin sinuous; vein 2 from beyond middle of cell; 3 from before angle; 4 from lower angle; 5 from below middle of discocellular, as near vein 4 as is vein 3; 6 from upper angle; 7 and 8 stalked; 9 and 11 from cell; 10 as a short spur from 9. Hindwing: vein 2 from well beyond middle of cell; 3 and 4 well apart; 5 nearer 4 than middle of discocellular; 6 from upper angle; 7 from before end of cell.

Type: *M. lantona* Schs.

M. lantona Schs. (88 f). *Male*: Very similar to *lucara*. Body and wings cinnamon buff: at angle of line on forewing pinkish cinnamon. Forewing: the line very faint on costal margin. Hindwing: the line cinnamon, the suffusions paler near inner margin. Forewing below light drab with pinkish cinnamon suffusions at outer line below costa; the line cinnamon on costa replaced from angle by the white line which is more vertical; below vein 3 the line appears again, threadlike and inbent; discal spot well marked, black. Hindwing below light cinnamon buff; the line almost subterminal, very faint and fine, clay colour; some pinkish cinnamon at anal angle. Expanse: 34 mm. French Guiana; Panama; Muzo, Colombia. *lantona*.

M. lucara Schs. (88 f). *Male*: Head and collar pale drab grey. Body above light drab, the thorax in front cinnamon drab. Forewing vinaceous buff, with some scattered black scales, slightly paler at base limited by an outcurved light cinnamon drab antemedial line; an outcurved whitish fazeia from middle of costa to base of vein 3, with a fine black discocellular line on its inner edge; some cinnamon suffusions postmedially to outer line chiefly within angle of line; line oblique from costa, excurved, snuff brown sharply angled, fuscous to inner margin, with a white line on its outer edge from angle excurved to termen at vein 2, at angle upcurved towards apex, angled and inbent with a fuscous line above it to just below apex where the costal edge is white; termen beyond curved white line drab grey, below the line to tornus purplish grey; cilia tipped with white. *lucara*.

Hindwing like forewing, the line straight; mikado brown suffusions before the line towards inner margin, and beyond the line to anal angle; a whitish shade from near apex to termen at vein 3, then along termen to anal angle. Forewing below light drab, marked as above, the line finer from below angle, more heavily marked on costa. Hindwing below largely pale pinkish buff to line which is paler and outcurved; suffusion at anal angle orange or pinkish cinnamon. Expanse: 36 mm. French Guiana; Amazons; S.E. Brazil.

plagiata.

M. plagiata *Wtr.* (88 g). *Male*: Body pale drab grey, the collar drab grey. Wings partly pale drab grey with a few scattered black scales. Forewing: base except on inner margin suffused with vinaceous buff; an antemedial light cinnamon drab line well outcurved below median to fold; a broad whitish lunule on outer edge of discocellular; outer line orange rufous on costa, outbent and acutely angled below vein 8 then inbent, slightly sinuous, carob brown, inwardly diffuse, edged with auburn, from below vein 5 outwardly with white which branches from angle to termen at vein 8 where it is joined by a white line above vein 8; termen with diffuse light drab shading. Hindwing: inner margin broadly suffused with ecru drab, the termen with light drab; line remote, almost subterminal, slightly sinuous, outwardly edged with white, inwardly with auburn from below vein 4, broadly to near cell, then narrowly near inner margin. Forewing below: the inner margin broadly white, the line not extending below vein 2. Hindwing below light cinnamon drab with more numerous black scales; the line inwardly edged with burnt sienna; an amber brown patch at anal angle. Expanse: male, 44–56 mm; female, 37–77 mm. The Guianas: Bolivia; S.E. Brazil; Paraguay.

12. Genus: **Biterolfa** *gen. n.*

Male: Antenna bipectinate, short on terminal third. Palpi porrect, short, thickly scaled. Legs hairy. Forewing: apex produced; termen incurved below apex and sinuous; vein 2 from middle of cell; 3 well before 4; 4 from lower angle; 5 below middle of discocellular; 6 near upper angle; 7 and 8 well stalked. Hindwing: termen rounded; anal angle acute; vein 2 just beyond middle of cell; 3 well before 4; 4 from lower angle; 5 below middle of discocellular; 6 well below upper angle; 7 from angle. Genitalia similar to those of *Psychocampa*.

Type: *B. althea* *Schs.*

althea.

B. althea *Schs.* (88 g). *Male*: Body and wings pinkish cinnamon; abdomen with a sublateral fuscous line, not reaching base or anal segment. Forewing: a fine orange cinnamon streak from before middle of costa to upper angle of cell and below vein 6, and a similar streak from cell below vein 2; outer line oblique, sayal brown, angled at vein 7 near termen, inbent, bister, subterminal, outwardly edged with purplish grey and a fine hair brown line which extends to apex and bifurcates below vein 3; cilia bister tipped with pinkish cinnamon. Hindwing: line postmedial outcurved at costa and straight to inner margin below middle; followed by a dark shade from costa bifurcating below vein 5, the outer branch fine, downbent to near termen at vein 2. Wings below very similar; no oblique shading at veins: line on hindwing fine, postmedial, evenly outcurved. Expanse: 41 mm. French Guiana.

13. Genus: **Ulmara** *gen. n.*

Male: Antenna bipectinate to tips. Frenulum present. Palpi hairy, porrect. Wings broad, the termen crenulate. Forewing: apex not acute; vein 2 from middle of cell; 3 well before angle; 4 from lower angle; 5 slightly above angle; 6 from upper angle; 7 and 8 on rather short stalk. Hindwing: termen crenulate; vein 2 from middle of cell; 3 before angle; 4 from lower angle; 5 from a little above angle; the discocellular from vein 5 very oblique and upbent to vein 6; 7 from before 6. The genitalia are near those of *Trogoptera*.

Type: *U. rotunda* *Dogn.*

rotunda.

U. rotunda *Dogn.* (88 g). *Male*: Body bister. Antenna tawny olive. Wings drab suffused with neutral grey; cilia verona brown. Forewing: a round fuscous spot at base below cell to vein 1 edged by the fine wavy verona brown antemedial line; a few white scales forming a point on discocellular; outer line fine, lunular dentate, outbent from costa, verona brown inwardly edged with light buff. Hindwing: line as on forewing, postmedial, preceded from vein 5 to inner margin by a broad fuscous shade. Wings below light drab largely mottled with pale silvery grey scales; the line as above, hair brown, fine, without any light buff edging; cilia benzo brown. Expanse: 40 mm. *Female*: A specimen received from Berlin Museum for identification probably belongs to this species, agreeing in the shape of the lines and venation. Body and wings light avellaneous buff irrorated with silvery light buff scales; the wings to line suffused with light drab; the lines cinnamon; the costa of hindwing broadly whitish. Wings below pale, the lines hardly perceptible. Expanse: 46 mm. Monte Tolima and Bogota, Colombia.

14. Genus: **Pamea** Wkr.

Male: Antenna bipectinate to tips. Palpi short, porrect, hairy. Legs hairy; terminal spurs on hind tibiae. Forewing: apex acute; outer margin straight below apex, rounded and inbent at tornus; vein 2 from middle of cell; 3 before angle; 4 from lower angle; 5 from below middle of discocellular; 6 from upper angle; 7 and 8 stalked; 9 and 11 from cell. Hindwing: apex and outer margin rounded; vein 2 from beyond middle of cell; 3 close to angle; 4 from lower angle; 5 from middle of discocellular; 6 and 7 from upper angle.

Type: *P. albistriga* Wkr.

P. albistriga Wkr. (88 g). *Male*: Body sayal brown. Forewing: base cinnamon buff to an pinkish *albistriga* cinnamon antemedial irregular line; medial space to outer line light cinnamon drab. terminal space pale drab grey, all irrorated with snuff brown scales; a fine dark line on discocellular; outer line fine, fawn colour, obliquely excurved from costa, rounded below vein 8 near termen and inbent; costal edge snuff brown; cilia snuff brown, paler at base, and tipped with white. Hindwing: base to line like medial space of forewing; terminal space as on forewing; the line postmedial; cilia as on forewing. Forewing below: cell and above vein 2 to costa and outer line cinnamon, inner margin and terminal space greyish white all irrorated with snuff brown; the black discocellular line more distinct; outer line fine; oblique to vein 7, vertical to vein 3, then inbent; some brownish shading on termen from vein 7 to vein 3. Hindwing below whitish with a few scattered brown scales; line faint, subterminal, slightly crenulate; cilia as above. Expanse: male, 30 mm. Nova Friburgo; Castro. Parana; Rio de Janeiro, Brazil.

P. nana H.-Schäff. (88 g). *Male*: Body and wings drab grey irrorated with fuscous; the outer line fine, *nana*. brownish olive, outwardly broadly edged with white. Forewing: costal edge clay colour; a faint clay colour antemedial wavy and vertical line; some black scaling on discocellular; outer line angled below vein 8 and slightly inbent; termen with fine dark striae from vein 8 to vein 4. Hindwing: line just beyond middle; termen with fine dark striae; cilia mass brown tipped with white. Forewing below: inner margin whitish, otherwise to near line cinnamon; line oblique to vein 7, excurved to vein 4 and again between 4 and 3, then inbent, preceded by white and hair brown shading between veins 2 and 6, outwardly edged with white which extends to termen from vein 3 to close above vein 4; termen otherwise hair brown; cilia fuscous with a pale line at base and tipped with white. Hindwing white irrorated with olive brown; costa suffused with buffy brown; line almost subterminal, snuff brown, crenulate; termen suffused with hair brown; cilia as on forewing. Expanse: 28 mm. Theresopolis, Brazil.

P. dotta sp. n. *Male*: Very similar to *albistriga*. Body and shading before outer line suffused with *dotta*. olivaceous drab; the line sayal brown, more broadly edged outwardly with white. Forewing: medial space light pinkish buff, crossed by a wavy pinkish cinnamon line; costal edge sayal brown; cilia fuscous tipped with white and a pale line at base. Hindwing: cilia snuff brown tipped with white and a cinnamon line at base. Both wings below more heavily irrorated with fuscous. The genitalia are quite different. Expanse: 28 mm. Castro, Parana.

P. ostia Drc. (88 g). *Female*: Body pale pinkish buff. Wings to line light cinnamon buff. Forewing: *ostia*. costa to line whitish interrupted by a wavy, almost medial, pinkish cinnamon line; from costa medially a broad white shade outbent along outer edge of discocellular and inbent to vein 3 at median; a few scattered black scales; line remote, outbent from costa, clay colour, edged above with white, angled at vein 8 near termen, inbent from vein 8, faintly sinuous, fine, verona brown, followed by light cinnamon buff, and a white line from angle at vein 8 outbent from vein 7 and sinuous along termen to anal angle. Hindwing: line mikado brown, post-medial inbent and curved to inner margin; space beyond light cinnamon buff; a broad subterminal dentate white shade; a few black scales. Forewing below pinkish buff; a black line on discocellular; outer line slightly visible from vein 6, with another fine line also from vein 6 outcurved along the subterminal white line, inbent from vein 4 and suffusing with the main line above inner margin; the white line from angle bifurcating to termen. Hindwing below yellowish white, the termen slightly suffused with cinnamon buff; line faintly visible in transparency; a fine cinnamon buff outcurved line. A few black scales on both wings. Expanse: 44 mm. Chiriqui, Panama. Described from type in Berlin Museum.

P. parostia sp. n. *Female*: Almost the same as *ostia*, much smaller in size and the frenulum more *parostia*. developed. The markings on wings reduced, the line finer, ochraceous tawny throughout, on underside of forewing single, more remote. Hindwing below with faint traces of a subterminal line. Expanse: 32 mm. Habitat: Unknown.

15. Genus: **Lurama** gen. n.

Male: Like *Ulmara*. Antenna and palpi as in that genus. Forewing: costal margin straight; apex not acute; termen straight, rounded at tornus; venation as in *Ulmara*. Hindwing: termen rounded; vein 2 from middle of cell; 3 well before angle; 4 from angle; 5 below middle of discocellular; 6 from upper angle; 7 before angle. Genitalia as in *Ulmara*.

Type: *L. penia* Dogn.

penia.

L. penia Dogn. *Male*: Body and wings warm buff with some buffy brown irrorations; costal edge of forewing, lines and cilia sayal brown. Forewing: a thick antemedial line, slightly outcurved; postmedial line thick, outangled at vein 7 then slightly inbent, continued on hindwing from vein 6 to inner margin above anal angle; a dark line on discocellular. Wings below similar, the line on hindwing followed by a similar line from costa, slightly outcurved. Expanse: 26 mm. Bogota, Colombia.

quindiuna.

L. quindiuna sp. n. (88 h). *Male*: Superficially like *penia*, differing in details. The lines finer, on forewing the antemedial outangled on costa, the postmedial more deeply angled, on hindwing slightly outcurved. Wings below as above, the hindwing without a line before the postmedial. Expanse: 32 mm. Paso del Quindiu, Colombia. Vein 5 on forewing near lower angle.

16. Genus: **Alheita** gen. n.

Male: Palpi short, hairy, slightly ascending, not reaching frons. Antenna bipectinate, the tips serrate. Tibiae hairy, the hind tibiae with short terminal spurs. Forewing falcate, the termen sinuous. Vein 2 from before middle of cell; 3 and 4 from lower angle slightly apart; 5 from middle of discocellular; 6 from upper angle; 7 and 8 stalked; 9 absent; 10 and 11 from cell. Hindwing: termen rounded or slightly oblique from apex to vein 5; vein 2 from before lower angle; 3 and 4 from lower angle; 5 from middle of discocellular; 6 and 7 from upper angle.

Type: *anoca* Schs.

anoca.

A. anoca Schs. (88 h). *Male*: Body and wings pinkish buff suffused with olivaceous without darker irrorations; cilia dark faintly tipped with pinkish buff; the line fine, olive brown, followed by a buffy brown narrow shade. Forewing: a fine antemedial line; a dark streak on discocellular; costal edge olive brown, edged below with light pinkish cinnamon; the line inbent from vein 10 to inner margin followed by a narrow olivaceous wood brown shade, expanding from vein 4 to inner margin and a similar terminal shade from vein 3 to vein 8; an olive brown streak below vein 10 to apex edged below with vinaceous buff. Hindwing: the line medial to inner margin below middle followed by an olivaceous wood brown shade. Wings below warm buff with an olivaceous tinge mottled with some darker hairlike scales. Forewing: discal spot larger; termen from vein 10 to slightly below vein 4 raw umber, edged inwardly by a curved pale vinaceous pink line which is outbent to termen above vein 8. Expanse: 34 mm. French Guiana; Amazons.

pulloides.

A. pulloides Dogn. (88 h). *Male*: Very similar to *anoca*. Forewing with the line vertical or slightly outbent to inner margin near tornus, very fine, ochraceous, the veins beyond light buff to near termen, edged above and below with buffy brown; termen with brownish suffusions. Hindwing: the line from costa near apex to below middle of inner margin, followed by a brownish shade and veins marked as on forewing. Forewing below: the dark terminal space edged inwardly by pale vinaceous pink, less curved and not outbent to termen. Expanse: 36 mm. Medina, Colombia.

bercaldia.

A. bercaldia sp. n. (88 h). *Male*: Similar to *pulloides*. Forewing: the postmedial line vertical; terminal space between veins 8 and 9 mottled with pearl grey; on both wings the veins beyond line are not dark edged. Forewing below with the terminal patch narrower, the white edging outbent to termen below vein 9. Hindwing below with a fuscous point on discocellular, and a subterminal darker line double from costa to vein 4. Expanse: 30 mm. Cayuga, Guatemala.

pulla.

A. pulla Dogn. *Male*: Body light cinnamon drab, the abdomen dorsally mottled with darker scales. Wings to line light cinnamon drab mottled with fine natal brown hairlike scales. Forewing: the line fuscous outwardly edged with cinnamon buff and faintly sinuous; a faint outcurved antemedial line; a black point on discocellular; termen broadly verona brown crossed by cinnamon buff veins, the interspaces irrorated with the same colour; a greyish streak below vein 9 to termen. Hindwing: the line verona brown outwardly edged with clay colour; outer space mikado brown, the veins clay colour. Wings below sayal brown; forewing with the terminal patch as in *bercaldia*; hindwing irrorated with verona brown, and with a similar subterminal shade. Expanse: 32 mm. San Antonio, Cali, Colombia.

cymbelina.

A. cymbelina sp. n. (88 h). *Male*: Body avellaneous. Forewing: base to a faint dark antemedial line vinaceous buff consisting of coarse hairlike scales; costa fawn colour; medial space cinnamon drab; a faint black line on discocellular; postmedial line slightly sinuous, cinnamon buff inwardly edged by a fine dark line, outwardly followed from vein 9 by a buffy brown shade expanding to tornus, and a similar terminal shade from vein 8 narrowing to a point at vein 4; a light vinaceous fawn shade incurved from below apex to termen below vein 4. Hindwing: base to line vinaceous fawn, also to termen from below vein 4 to inner margin; line dark, postmedial; termen from apex to vein 4 mostly army brown. Forewing below vinaceous wood brown irrorated

with fuscous hairlike scales; a prominent black line on discocellular finely edged with whitish scales; the dark terminal patch broadly edged above and inwardly with pale vinaceous fawn. Hindwing below like forewing without any markings. Expanse: 27 mm. Taperinha, Amazons; French Guiana.

A. subnotata Dogn. (88 h). *Male*: Body and wings to line light fawn colour, terminal area cinnamon *subnotata*. drab; line vinaceous brown outwardly faintly edged with light russet vinaceous. Forewing: a very faint darker line on discocellular; postmedial line inbent from costa to beyond middle of inner margin; a pale greyish vinaceous streak above vein 8 at termen, and traces of a similar sinuous shade from vein 5 to termen at vein 3 then to tornus. Hindwing: the line postmedial downbent near inner margin. Wings below cinnamon drab irrorated with chestnut brown. Forewing: a thick fuscous line on discocellular; on termen before apex a chestnut brown space from below costa to below vein 4 inwardly edged by a curved whitish line. Hindwing: some white hairs on costal margin; an apical dark patch as on forewing from apex to vein 4 inwardly edged by a curved white line, continued from vein 4 to inner margin as a wavy chestnut brown line. Expanse: 37 mm. Pebas, Amazons.

A. rionica sp. n. (88 h). *Male*: Body and wings deep purplish grey slightly tinged with brown. Forewing: *rionica*. apical third of costa deep chrome and orange; a wavy black antemedial line; postmedial line faint, almost straight and vertical defined by raw sienna spots at veins 3 and 1; an incurved lilacine line from below apex at termen to termen at vein 2, followed by argus brown; cilia tipped with pinkish cinnamon. Hindwing: a raw sienna spot beyond lower angle of cell. Wings below mostly deep mouse grey mottled with darker scales; cilia clay colour. Forewing: a black and whitish line on discocellular; termen from vein 8 to vein 2 fuscous black, inwardly edged with pale drab grey. Hindwing: fuscous black suffusions at apex. Another male with similar genitalia and from the same locality is darker, the raw sienna spots at inner margin of forewing and on hindwing larger; apex of forewing with some chrome markings greatly reduced. A female also from Teffé, submitted by the Berlin Museum, is dark fawn colour with a purplish tinge. Forewing with a fine dark postmedial line and a raw sienna spot at inner margin. Hindwing somewhat darker; a fine medial dark line and a round raw sienna spot beyond lower angle of cell. Forewing below deep vinaceous grey; a large cinnamon buff spot beyond cell from subcostal to vein 3; a black line on discocellular; a dark postmedial line outcurved, well defined, not reaching inner margin; the dark terminal shade without the pale edgeing. Hindwing mostly deep brownish drab; some dark scaling at discocellular; a medial dark line vertical to vein 4 and curved to inner margin. Expanse: male, 32 mm; female, 35 mm. Teffé, Amazons.

A. caudina Schs. (88 i). *Male*: Body fawn colour. Forewing to line buffish fawn colour, with a few scattered black scales; a black streak on discocellular; postmedial line white, slightly incurved from costa and inbent from vein 5; terminal area chiefly liver brown, towards apex pale drab grey. Hindwing: base to line fawn colour; termen sanford's brown; line white, medial. Wings below vinaceous russet with a few black scales. Forewing: a black streak on discocellular; line white incurved from costa, outcurved at veins 4 and 3, then inbent, followed from vein 4 to termen and costa with chestnut brown. Hindwing: a black streak on discocellular; line white, postmedial, vertical from costa to vein 4, then slightly upcurved to inner margin; the anal angle with a tuft of inbent chestnut brown hairs. Expanse: 33 mm. French and British Guiana; Amazons; Venezuela.

A. subrubiginosa Dogn. (88 i). *Male*: Body dusky drab. Forewing: costal edge cinnamon brown; base *subrubiginosa*. broadly deep brownish drab tinged with fawn colour above inner margin; an oblique black line in cell; a medial dark greyish brown shade, outcurved to discocellular spot and inbent to before middle of inner margin; discal spot oval, deep quaker drab followed by a dark splash; postmedial line remote, broad on costa, dark greyish brown, outbent, angled at vein 8, inbent, narrow, sepia, followed by a narrow light brown shade; terminal area deep brownish drab; an incurved chestnut brown shade from termen at vein 8, below vein 4 brick red and expanding to termen at vein 1; costal margin beyond postmedial cinnamon buff; termen very narrowly and cilia brick red. Hindwing deep brownish drab, line fuscous, just beyond middle; a brick red subterminal shade from vein 3 expanding to termen from vein 2 to anal angle. Wings below raw sienna. Forewing: a black spot on discocellular; line very fine and faint, fuscous at inner margin, the fuscous extending to base; a subterminal fine cinnamon brown and broader hair brown shade from vein 8 to vein 4. Hindwing: a fine chestnut brown line on discocellular; line fine, postmedial, slightly outcurved. Expanse: 39 mm. Medina, Colombia; Merida, Venezuela.

17. Genus: **Tarema** Schs.

Male: Antenna bipectinate, the tips serrate. Forewing broad, termen only slightly inbent: vein 2 from before middle of cell; 3 before lower angle; 4 from lower angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 stalked; 9 and 11 from cell. Hindwing: costa slightly convex; termen rounded; vein 2 from beyond middle of cell; 3 close to angle; 4 from lower angle; 5 from middle of discocellular; 6 and 7 from upper angle.

Type: *T. rivara* Schs.

fuscosa. **T. fuscosa** Jones (88 i). *Male*: Body and wings olivaceous drab. Forewing: costal edge light buff; a long dark oblique line on discocellular finely edged with whitish buff; a faint antemedial line; postmedial line more remote than in *rivara*, whitish buff, slightly inbent from costa to vein 5, then more inbent, followed by a parallel white line, diverging from vein 5 to termen at vein 2, the space between from below vein 2, and the termen from apex to vein 3 army brown, the terminal part crossed by a whitish line on vein 7. Hindwing: a small dark streak on discocellular; an army brown line from costa near apex to below middle of inner margin, inwardly pale edged; terminal space somewhat darker with some rufous at line from vein 5 to vein 2. Forewing below hair brown in disc, below cell and vein 2, also close to line irrorated with whitish and massicot yellow; the discocellular spot as above. Hindwing below: a partly double whitish line filled in with dark scaling; some reddish scaling at apex. Expanse: 32 mm. Nova Friburgo; Santa Catherina, Brazil. Easily distinguished by the white terminal line along vein 7 of forewing.

rivara. **T. rivara** Schs. (88 i). *Male*: Head and collar light buff. Thorax buff pink, abdomen light pinkish cinnamon. Forewing: costal edge white to postmedial line; base to postmedial below cell to inner margin and terminal space apricot orange; cell and to costa and postmedial line mottled pale drab grey and buffy brown; a faint outbent antemedial line; an oblique fuscous spot edged with white on discocellular; postmedial line inbent from costa, white, outwardly edged with hair brown; a white line from costa near postmedial slightly incurved and outbent expanding to termen between veins 4 to 2; cilia buff white. Hindwing apricot orange; costal margin whitish to line; a benzo brown line on discocellular; line benzo brown, postmedial at costa, straight to middle of inner margin. Forewing below as above, but the inner margin broadly white to line which is subterminal, double, excurved from costa to vein 4, then outcurved to close to termen, and inbent below vein 2. Hindwing below duller; a round fuscous spot on discocellular; line fine, subterminal and sinuous. Apices of both wings below ferruginous. Expanse: 27 mm. Castro, Parana.

macarina. **T. macarina** sp. n. (88 i). *Female*: Head and collar drab grey, the thorax and abdomen suffused with light pinkish cinnamon. Forewing: costal margin whitish; cell and above vein 2 to line mottled tawny and pinkish buff, below cell to inner margin pinkish cinnamon; discocellular spot, postmedial and subterminal lines as in *rivara*; the terminal space cinnamon brown. Hindwing: costal margin to line white; base below cell pinkish cinnamon; a black streak on discocellular; line from beyond middle of costa to middle of inner margin, whitish, outwardly broadly bister; termen broadly buff grey irrorated with brown, the veins cinnamon buff. Wings below light buff mottled with cinnamon brown, the discal spots and lines as in *rivara*; termen below apex of forewing, and patch at apex of hindwing cinnamon brown; the subterminal line of hindwing closer to termen. Expanse: 27 mm. São Paulo, Brazil. A male of this species is in the Berlin Museum.

18. Genus: **Aceclostria** gen. n. (*Th.-Mieg i. l.*)

Male: Antenna bipectinate, diminishing towards tips. Palpi upturned, short, hairy. Forewing produced, excurved below apex and sinuous. Cell long, two-thirds of length of wing; vein 2 from beyond middle of cell; 3 near lower angle; 4 from angle; 5 from middle of discocellular; 6 from upper angle; 7 and 8 moderately stalked; 9 and 11 from cell. Hindwing with termen rounded; cell half the length of wing; vein 2 from beyond middle of cell; 3 close to angle; 4 from angle; 5 from middle of discocellular; 6 and 7 from upper angle.

Type: *A. mus* Vuill.

mus. **A. mus** Vuill. (= *deprava* Schs.) (88 i). *Male*: Body and wings varying from pale drab to light mouse grey with light drab suffusions and some black irrorations. Forewing: an inbent hair brown antemedial line, inbent from a small black spot on costa; a round hair brown spot at discocellular crossed by a greyish line; postmedial line fine hair brown outcurved beyond cell and sinuous, marked by a black spot on costa; costal edge dresden brown; cilia dresden brown tipped with white. Hindwing: the line postmedial better defined towards inner margin. Wings below: anterior half light cinnamon drab, otherwise pale drab grey, all more thickly irrorated with dark scales. Forewing: the greyish line on discocellular more prominent; postmedial line thicker, less sinuous. Hindwing: the line thicker, outcurved, nearer termen. Expanse: male, 31 mm; female, 35 mm. São Paulo, Brazil; Paraguay; Tucuman, Argentina.

19. Genus: **Adalgisa** gen. n.

Male: Frenulum present. Antenna bipectinate to beyond middle, terminally serrate. Palpi short, upturned, not reaching frons. Tibiae with long tufts. Forewing falcate, the tips rounded; vein 2 from close to end of cell; 3 and 4 stalked; 5 from middle of discocellular; 6, 7, 8 stalked; 9 and 11 from cell. Hindwing: costa and termen evenly rounded; inner margin prolonged at anal angle; vein 2 from near angle; 3 and 4 on short stalk; 6 and 7 from upper angle.

Type: *A. croesa* Schs.

A. croesa *sp. n.* (88 i). *Male*: Body snuff brown with darker scaling at base of abdomen. Wings to *croesa*. line cinnamon drab with a few black scales. Forewing: an antemedial, almost medial snuff brown line, dentate vertical across cell, inbent below cell to near base of inner margin, followed in cell by a fuscous shade to the sinuous fine white line on discocellular; interspaces beyond cell to line fuscous, the veins buffy brown; costal margin to apex buff brown, the costal edge vinaceous fawn; outer line incurved from vein 10 to vein 5 chestnut brown edged inwardly with white, below vein 5 outcurved and crenulate inwardly edged with white from vein 2 to inner margin and between veins 4 and 2 by quadrate hyaline spots; the line is followed from vein 8 to below vein 3 by warm buff irrorated with ochraceous salmon and black; at vein 10 the line is outcurved widening to apex, with an elongated hyaline spot below it to vein 8, this latter white at termen; termen light, cinnamon drab. Hindwing: the line vertical, black from costa to vein 6 inwardly edged with white, from vein 6 to inner margin wavy, crenulate, cinnamon brown inwardly edged with light buff from vein 6 to vein 4, and from vein 2 to inner margin with white; between veins 4 and 2 the line widens and is preceded by a small hyaline spot in fork of veins 4 and 3, and by a larger hyaline spot between veins 3 and 2; between vein 4 and 2 the line is followed by a rufous patch; termen broadly light cinnamon drab. Wings below light cinnamon drab; the edging of lines pinkish buff, followed on hindwing by fuscous shading from vein 7 to vein 4, and small fuscous spots at inner margin. Expanse: 36 mm. Sta. Catherina. Brazil: Oyapock River, French Guiana.

A. stellifera *sp. n.* (88 i). *Male*: Body light cinnamon drab. Forewing: base light drab limited by a *stellifera*. curved inbent fawn colour line outwardly edged with light buff; medial space drab crossed by a fine silvery white inbent line on discocellular; postmedial line cream colour outwardly edged with army brown, incurved from vein 9 to stalk of 7 and 8, then crenulate on each interspace, the line preceded by semihyaline silvery white spots between veins 2 and 4, by army brown to discocellular, and between veins 2 and 4, with some black scales on the army brown; following the line some ochraceous buff in fork of 7 and 8, and some warm buff between 7 and 4 well irrorated with fuscous, from vein 4 to just below vein 2 an expanding light buff shade irrorated with olive grey; termen fawn colour, widest between veins 4 and 8; costa from above discocellular to near apex drab; a white line from postmedial at vein 9 to termen at vein 8. Hindwing: base drab; a medial line as on forewing preceded by a small hyaline spot below vein 3, and a minute spot above 3: no pale shading beyond the line; outer space fawn colour with a round postmedial orange cinnamon spot between veins 3 and 2. Wings below duller. Expanse: 28 mm. Molinas, Paraguay.

20. Genus: **Roelmana** *gen. n.*

Male: Antenna bipectinate, short beyond middle. Palpi upturned to frons, thickly scaled, smooth. Frenulum slight. Forewing: apex acute, falcate, termen slightly sinuous: vein 2 from before middle of cell; 3 close to 4; 4 from lower angle; 5 from middle of discocellular; 6—8 stalked. Hindwing: anal angle bluntly produced; vein 2 well beyond middle of cell; 3 close to 4 at lower angle; 5 from middle of discocellular; 6 from upper angle; 7 before angle. Replaces in the *Lacosominae* *Roelofa* of the *Mimalloninae*.

Type: *R. maloba* Schs.

R. maloba Schs. (88 i). *Male*: Head and collar pinkish cinnamon. Thorax and forewing cinnamon *maloba*. drab. Abdomen and hindwing vinaceous russet. Some fan-shaped white scales along costa of forewing and inner margin of hindwing; discocellular spots hyaline broadly B-shaped. Forewing: an antemedial pinkish cinnamon spot below cell, and similar scaling mottled with vinaceous russet at base of inner margin; line fine from a small black spot on costa, oblique, excurved with bluish white scaling above it, angled and inbent from vein 7, crenulate outwardly, finely edged with bluish white scaling and a cream white spot between veins 6 and 7, and from vein 3 to inner margin followed by a large triangular white patch crossed by a dark dentate line; some terminal blue white scaling from vein 4 to apex. Hindwing: a fine and faint dark line almost sub-terminal followed by white spots at apex and above anal angle. Wings below as above, somewhat duller. Expanse: male, 45—55 mm; female, 57 mm. Guatemala; French Guiana: Amazons: Joinville, S.E. Brazil. Also in the Berlin Museum.

The following two species have not been identified:

Mimallo saturata Wkr. Female: Reddish brown. Thorax with luteous hairs laterally behind. Abdomen red with *Mimallo* yellow hairs and a lateral orange stripe; anal hairs luteous. Forewing: outer two thirds slightly tinged with purplish: discal *saturata*. spot small, testaceous, edged with black; a slender whitish somewhat oblique line outwardly edged with blackish from near tip of costa to inner margin at three fourths. Hindwing: reddish, a very oblique medial purplish line. Expanse: 52 mm. Rio de Janeiro. Type in Fry collection, probably lost.

Perophora albescens Jones. Male: Head, palpi, and antenna ochreous. Body white mottled with ochreous and scattered black scales; dark dorsal tufts on segments 4 to 6 of abdomen. Wings white irrorated slightly with black. Forewing: *Perophora* costa and lines mostly ochreous: a wavy antemedial line more distinct from vein 2 to inner margin; postmedial line irregular. *albescens*.

reddish from vein 3 to costa, projecting at veins 7 and 8, preceded by ochreous suffusion filling medial area below vein 2, except a small triangular space between base of vein 2 and antemedial line; terminal area suffused with ochreous fuscous except a narrow line following postmedial; a darker lunular patch from veins 3 to 5. Hindwing outwardly suffused with ochreous; a very indistinct diffuse, ochreous antemedial line, heavily suffused with reddish brown at inner margin and at veins 3 and 4. Wings below ochreous white irrorated with black; postmedial line distinct; terminal area paler. Expanse: 30 mm. São Paulo, S.E. Brazil. Type in British Museum.

Additions

By the kindness of Dr. SCHAUS we have been enabled subsequently to figure also the following species from water-colour sketches by Mr. NOYES:

<i>Aleyda accipiter</i> (p. 641)	pl. 86 g
<i>Lacosoma asea</i> (p. 662)	pl. 86 g
<i>Lacosoma zonoma</i> (p. 662)	pl. 86 g
<i>Lacosoma valva</i> (p. 663)	pl. 86 g
<i>Tolypida amaryllis</i> (p. 664)	pl. 86 g
<i>Vanenga mera</i> (p. 664)	pl. 86 g

11. Family: Bombycidae.

The American faunistic region, according to our present knowledge, contains about 200 forms which are more or less correctly placed to this group the principal range of which is the Indo-Australian region. For particulars about this family we refer the readers to Vol. X, p. 433. In the palaearctic and Ethiopian regions there occur so few characteristic representatives of this family that we mentioned in a very brief way their systematical morphological relations in Vol. II, p. 189, and Vol. XIV, p. 283. We are sorry to confess that we know almost next to nothing about the biology of the American representatives: the early stages are entirely unknown, so that nothing whatever can be said about the outward appearance of the *Epiinae* (see below) being evidently closely allied to the genuine *Bombycidae* in their early stages. The second subfamily joined with the *Bombycidae*, the *Zanolinae*, differs biologically — only the larvae of 2 North-American representatives are known hitherto — so widely from the usual types of the genuine Bombycid larvae that an unprejudiced observer will at first object to the insects being ranged here. As to the latter divergent group, the *Apatelodes* — presumably named owing to the resemblance of the larvae to the Noctuid genus *Apatela* (= *Acronycta*) — have undergone many systematical changes; they were probably the most correctly inserted by PACKARD in the Notodontid tribe, whilst they were hardly less justly regarded as *Eupterotidae*. According to recent researches, however, they are morphologically so closely allied to the *Bombycidae* that we decided to annex them to this group as a subfamily, although they are hardly connected with them by their outward appearance. The genus *Zanola* resembles more certain *Liparidae*. A much greater external resemblance to the smaller eastern Bombycid forms is exhibited by the *Epiinae*, especially in the shape of the wings. Particularly similar is the genus *Quentalia*, formerly known as *Carthara*. Some representatives of *Colla* recall the *Ocinera* etc. The imagines are exclusively nocturnal insects, being only captured at night on the lantern, where they sometimes appear in great numbers, as for instance the Mexican small species of *Apatelodes*. We had formerly mentioned at another place that the inner margin of the hindwing in the resting insect remains uncovered and consequently exhibits a colouring similar to that of the forewing, in contrast with the otherwise pale hindwing.

As to the early stages we merely know that, as we stated above, the larva of *Apatelodes torrefacta* is very similar to that of the palaearctic *Apatela*; moreover, the entirely flat plateshaped eggs exactly correspond with the disk-shaped flat ones of *Acronycta*, which are partly deposited like tiles one above the other. (M. DRAUDT.)

No typical species of *Bombycidae* occur in America, but the *Epiinae* are well represented in tropical America, though none have been found as yet in the United States. The true *Bombycidae* have vein 8 on hindwing highly arched from base and usually connected with vein 7 by a bar, whereas in the *Epiinae* and *Zanolinae* (DRAUDT) vein 8 is deflected near base, touching vein 7, or anastomosing with it and then continuing almost straight towards apex.

The *Epiinae* and *Zanolinae* can be separated by vein 8 on forewing, which in the former is downbent or down arched as in the *Bombycidae*, whereas in the *Zanolinae* vein 8 is straight or convex; in many species veins 8, 9, 10 on costa are also convex. Nothing is known of the larvae of the *Epiinae*. All the genera have vein 10 absent except *Arotros* in which it is present. (W. SCHAUS.)

Key to the genera of Epiinae.

A. Forewing with apex rounded.

a. Vein 10 absent.

a¹. Vein 3 of forewing well before lower angle.*Epia*.b¹. Vein 3 of forewing close to or from lower angle.*Colla*.

b. Vein 10 present.

Arotros.

B. Forewing with apex not rounded.

a. Forewing with apex produced.

Quentalia.

b. Forewing with apex acute.

a¹. Abdomen not extending beyond hindwing and without tufts.a². Veins 3 and 4 on forewing from cell.*Anticla*.b². Veins 3 and 4 on forewing stalked.*Cheneya*.b¹. Abdomen extending beyond hindwing and with tufts.*Tamphana*.1. Genus: **Epia** Hbn. (=Anthocroea Btlr.)

Male: Palpi short, upturned, smoothly scaled. Antenna bipectinate. Legs and base of tarsi hairy; hind tibia with two terminal spurs. Forewing: costa straight; apex usually rounded; termen slightly inbent; vein 2 from middle of cell; 3 well before angle; 4 from lower angle; 5 from above middle of discocellular; 6—9 stalked; 10 absent; 11 from cell. Hindwing rounded; anal angle faintly acute; vein 2 from middle of cell; 3 well before angle; 4 from lower angle; 5 from just above middle of discocellular; 6 and 7 stalked; 8 connected with 7 near base.

Type: *E. domina* Cr.*domina*.

E. domina Cr. Female: Body and wings cinnamon. Forewing slightly darker at base, and traces of a medial fascia below cell; postmedial line double, the inner broad, broken by veins, the outer fuscous from costa to vein 4 preceded by a white line, followed by large white spots reaching vein 3. Hindwing brighter at anal angle; a well marked postmedial line. The underside according to Cramer dark yellow with four transverse brownish red, outcurved lines. Expanse: 69 mm. Surinam. The figure shows distinctly the characters of venation present in the other species placed in *Epia*.

muscosa.

E. muscosa Btlr. (♂ = *cuneifera* Btlr.) (89 a). Male: Forewing vinaceous drab, vinaceous fawn or pale olive ocher; antemedial line fine, black, outcurved with some olive ocher on either side at inner margin; a large elongated pale olive ocher spot on costa from before middle to close to postmedial line, edged behind with fuscous; an oblique mottled spot from inner margin postmedially to above vein 2, sometimes enclosing a round greenish white spot at vein 2, and edged with hazel or chestnut brown; postmedial line almost vertical, fine, black, partly edged outwardly with white and followed from vein 5 to costa by a narrow fuscous shade; termen usually from vein 2 to costa pale olive ocher, frequently with darker olive mottling. Hindwing variable as on forewing; the postmedial lines approximated at inner margin, the outer line with a small yellow angled line and brazil red suffusions above anal angle which has some terminal yellow scaling. Forewing below very much as above, but the costal spot diffuse, not dark edged behind, its outer edge continued as a first postmedial line. Hindwing below variable in colour, medial pale olive ocher fascia to vein 4 inwardly defined by a long black line on discocellular, outwardly by the postmedial line; some similar colouring at anal angle and slightly at middle of outer margin. Female: Forewing largely ochraceous tawny, the termen except towards apex cinnamon brown; costa, end of cell, medially below cell, and subterminally from vein 5 to near apex oil yellow; antemedial line fine, army brown, outcurved; postmedial line faint sinuous, bifurcating at vein 4, the inner part inbent to inner margin near antemedial, followed from costa by a fine fuscous vertical line partly edged with pale quaker drab. Hindwing vinaceous cinnamon suffused with English red above and beyond a yellowish spot on termen at anal angle; inner margin mottled with white scales and black lines; the outer lines fuscous, wide apart, converging near inner margin, with a yellow spot near it. Wings below mostly mustard yellow. Forewing: space between outer lines and termen except near apex onion-skin pink. Hindwing: a fuscous and purplish streak at inner margin expanding to outer line. Expanse: Male 40 mm; female 56 mm. Guatemala to Bolivia; Amazons; French Guiana.

vulnerata.

E. vulnerata Fldr. (89 a). The species I have identified as *vulnerata* is very similar to *picta*, and the chief difference is its smaller size and the white shading at the anal angle of the hindwing on the underside. FELDER's figure shows a much paler form, the subbasal angled line double and a small spot on costa at apex as in my specimens: in *picta* there is no apical spot on costa and the subbasal line is broad and diffuse. In *madeira* the angled line is single and there is no apical spot, otherwise it approaches *vulnerata* in colour. Expanse: 33—35 mm. Amazons; French Guiana; Peru.

E. picta Schs. (89 a). Male: Body rufous; palpi in front yellow on second joint; antennae light brown, *picta*. the shaft irrorated with white; collar mottled behind with white hairs; a few white irrorations on tegulae. Forewings: base of costa rufous, below it a lilacine shade mottled with brown; basal half of inner margin light brown; a yellowish streak below cell and vein 2 to near termen cut by the rufous lines; a rufous streak below this broadening to inner margin on outer half; a dark brown shade in cell antemedially, extending as a dull grey shade between veins 2 and 3 to termen; above this in cell and between veins 3 and 4 a lilacine grey shade suffusing with a similar broad outer shade from costa, leaving a triangular brownish shade on costa within the postmedial line; antemedial line outcurved, wavy, dark red; a dark medial line below vein 2; postmedial slightly lunular, dark red from veins 5 to 7, and below vein 2 fine, greyish and hardly perceptible on the pale portion of wing; a fine deeply lunular outer dark grey line; some subterminal rufous spots, and a small white spot between veins 2 and 3; termen shaded with dark grey from below vein 6; the tornus rufous. Hindwings rufous brown, becoming dark red at anal angle; the two outer lines fine, fuscous, separated by a yellow shade near inner margin; inner margin fuscous brown with white irrorations. Forewings below pale reddish, the inner margin broadly yellowish white; the costa ochreous yellow; postmedial line straight, fuscous brown and thick, from costa to vein 4; outer line finer, lunulate; apex yellow; termen dark rufous. Hindwing below purplish. the base and costal margin rufous; postmedial line almost straight, the outer line finer, lunular. Female: Body and wings paler rufous; abdomen with darker subdorsal lines. Forewings: a greyish purple shade between veins 2 and 4 from cell to termen; white irrorations on costal margin and broadly at apex; costa ochreous yellow; a faint fuscous postmedial line, finely lunular and hardly in bent. Hindwings: anal angle broadly dark red; fuscous lines only visible near inner margin; whitish shadings medially on inner margin. Forewings below dark grey, becoming brownish yellow at apex and terminally; the costa dark ochreous yellow; traces of a fine dark postmedial line; outer line fine, lunular, well defined to near inner margin. Hindwings below dark brown, the basal half shading to light brown terminally, the disc heavily irrorated with white: postmedial line very faint; outer line fine, lunular, well defined. Expanse: Male, 45mm; female, 60 mm. Antioquia, Colombia (elevation, 5 000 feet).

E. madeira Schs. (89 a). Near *vulnerata*. Male: Head reddish brown; palpi in front buff. Thorax *madeira*. lilacine brown. Abdomen reddish brown. Forewings chiefly grey, the inner margin below vein 2 pale reddish brown; costa reddish brown streaked with white; a yellowish white space at base limited by a reddish brown line, from costa at base to vein 2 near cell, sharply angled and in bent to submedian; basal third of inner margin below submedian yellow; geminate medial and postmedial fine lines from vein 2 to inner margin; a black line on discocellular followed by a similar oblique streak to costa, edged anteriorly by an olive buff shade; a fine dark outer dentate line being part of the geminate postmedial line; faint subapical yellowish shading; a subterminal white spot between veins 3 and 4, and a similar point below veins 3. Hindwings pale reddish forming a darker subterminal shade, which is more pronounced and reaches termen from vein 2 to inner margin; a fine fuscous outer line shaded on either side with yellow. Forewings below pale roseate buff, the costa and space above vein 4 reddish brown, crossed by a short black streak on discocellular; a postmedial in bent black line and a lunular outer line; the subterminal white spots as above. Hindwings below roseate, the costal margin reddish brown; the postmedial and outer lines faint; a dark streak below cell and vein 2 from base to postmedial line. Expanse: 38 mm. Rio Madeira, Brazil.

E. intricata Drc. "Male: Head, antennae, collar, tegulae, thorax, and abdomen pale olivebrown. Forewings *intricata*. pale olive-brown, crossed from the costal to the inner margin by two rather wide dark olive-brown bands, which are united just below the cell; the base and the apex of the wing olive-brown; a greyish-white marking on the outer margin above the anal angle and a black dot at the end of the cell; the cilia yellowish brown: hindwings pale yellowish fawn colour, with some dark markings on the inner margin. Expanse: $1\frac{3}{4}$ inch. S. E. Peru; Santo Domingo, 6 000 feet."

E. casnonia Drc. (89 a). Male: Head light vinaceous cinnamon. Collar pale greenish buff. Thorax dark *casnonia*. olive buff. Abdomen above vinaceous fawn. Forewing cream buff; inner margin except at base suffused with fawn colour to median and vein 3; lines army brown; antemedial outcurved, vertical below vein 2; a faint paler parallel medial line bifurcating below vein 2 and enclosing a round spot of ground colour, its outer edge really part of inner postmedial line; postmedial double, vertical; termen with dark suffusions especially between veins 4 and 5. Hindwing cinnamon buff with a greenish tinge, almost cinnamon at anal angle; medial line vertical, faint, in bent at inner margin, the postmedial parallel with it, army brown well defined. Wings below largely isabella colour, the outer lines well marked, wider apart; anal space of hindwing partly white. Female: Forewing to postmedial, also apex, orange cinnamon; antemedial and postmedial lines hardly traceable, between them below cell a dark purple shade; termen from vein 6 to inner margin, also space between postmedial lines, suffused with dark purple; small cream coloured spots on outer edge of line between veins 3 and 4, and 5 and 6. Hindwing orange cinnamon, the lines black. There is considerable variation especially in the male which sometimes has the forewing drab grey. Expanse: Male 34 mm; female 44 mm. Guatemala to Costa Rica.

E. lebethra Drc. Male: Forewing: costal margin to postmedial olivaceous, below it from base of inner *lebethra*. margin a broad creamy white fascia, also to postmedial, edged behind by a fuscous line, the triangular space

below it, also between postmedial line and partly on termen, cinnamon drab faintly tinged with olivaceous; postmedial line double, the first line heavily marked, the second line very fine diverging somewhat towards inner margin; small cream coloured spots on termen between veins 3 and 4, and 5 and 6, and similar mottling towards apex. Hindwing vinaceous tawny; first postmedial line darker slightly incurved, the second line hair brown slightly outcurved and well marked; termen narrowly pale orange yellow. Forewing below greenish yellow, the hindwing partly suffused with vinaceous tawny, the lines as in *casnonia*. Female: Forewing: the fascia below costa and apical space vinaceous fawn, the costa, triangular space above inner margin, and termen below vein 5 deep brownish vinaceous. Hindwing orange cinnamon, the lines faint. Expanse: Male 34 mm; female 45 mm. The Guianas.

hiemalis.

E. hiemalis *Bltr.* Male: Head cinnamon. Body above dark vinaceous drab, underneath usually orange cinnamon. Forewing mostly bay, the inner margin suffused with chestnut; costal edge orange cinnamon; cell except base and a large apical space irrorated with white hairs; some white hairs on costal margin above a dark postmedial patch; antemedial dark line outcurved and dentate on veins; postmedial line single, fuscous, lunular preceded by dark olive between veins 2 and 4, and a small spot below vein 2, also followed by some small greenish spots; a large round greenish spot medially below vein 2 at antemedial line. Hindwing bay or ochraceous tawny, the postmedial fine, sinuous, the medial broader and diffuse. Forewing below deep brownish drab or buffy brown, the costal edge and postmedial line as above. Hindwing below brownish drab or buffy brown, the lines as above. Female: Forewing rather brighter than the male, the markings more confused, the greenish spots above vein 1 larger, but sometimes absent; traces of two postmedial lines well defined on underside; no white scales in cell nor at apex. Hindwing usually orange cinnamon darker shaded along inner margin. Expanse: Male 30 mm; female 47 mm. French Guiana; Amazons.

lunilinea.

E. lunilinea *Schs.* (89 a). Male: Head: palpi brown; frons whitish buff; some brown hairs at base of antennae; shaft of antennae white, the pectinations brown. Body and wings dull purplish grey. Forewings with the lines slightly darker; antemedial line geminate, wavy, slightly outcurved; a medial lunular line outbent and touching the dark discocellular line, the lunules inverted and touching the postmedial, forming indistinct spots; postmedial geminate, lunular. Hindwings tinged with whitish on costal margin; a postmedial geminate line, hardly visible; some dark shadings on inner margin. Wings below duller with only the postmedial lines faintly indicated. Expanse: 58 mm. Rockstone, Essequibo River, British Guiana.

erdae.

E. erdae *sp. n.* (89 b). Male: Body above dark greyish brown mottled with olivaceous buff hairs, underneath light buff with dark transverse lines. Forewing acute, the outer margin straighter, hair brown, the inner margin and termen suffused with fuscous; the disc more thinly scaled; costal edge drab; postmedial line fuscous double, slightly inbent, lunular; termen narrowly and cilia light drab irrorated with fuscous; cilia on inner margin avellaneous on basal half. Hindwing chaetura drab, the disc pale drab grey, semihyaline; cilia on inner margin avellaneous; the two lines near termen only defined on underside where the anal angle is partly orange buff. Expanse: 33 mm. Upper Amazons, Brazil. Type in U.S. Nat. Museum Washington.

2. Genus: **Colla** *Wkr.*

Male: Palpi short, upturned, hardly reaching frons; hind tibia with 2 terminal spurs. Forewing: apex rounded; termen usually rounded, in male of *glaucescens* straight and inbent; vein 2 from beyond middle of cell; 3 close to or from angle; 4 from angle; 5 from near upper angle; 6—9 stalked; 10 absent; 11 from cell or sometimes stalked with 6—9. Hindwing: vein 2 well beyond middle of cell; 3 and 4 from lower angle; 5 above middle of discocellular; 6 and 7 stalked; 8 connected with 7 near base.

Type: *C. glaucescens* *Wkr.*

rhodope.

C. rhodope *Dru.* (= *opalina* *Bltr.*) (89 b). Male: Body above isabella colour; tegulae partly white; abdomen laterally and below white. Wings rather thinly scaled, white. Forewing: costal edge antemedially and postmedially isabella colour, the markings light greyish olive; an antemedial spot in cell and an inbent line below cell; a fine line on discocellular; an inbent double and irregular postmedial line, outbent below vein 3; a marginal macular line; a terminal line. Hindwing: inner margin densely scaled; a dark spot above angle sometimes preceded below vein 2 by a postmedial and subterminal spot, more distinct on underside. Forewing below showing most of the markings in transparency. Female: Forewing: the markings similar to male but all broader; outer postmedial line lunular, also the marginal line. Expanse: Male 39 mm; female 40—48 mm. Mexico to Paraguay; the Guianas.

netrix.

C. netrix *Stoll.* Female: Body above yellow ocher. Thorax with a lateral white line; abdomen laterally white. Wings white. Forewing: lines yellow ocher; antemedial fascia wide on costa outcurved ending in a

point on inner margin; a broad postmedial fascia; broad subterminal and terminal lines. Hindwing; a postmedial line from costa to inner margin; a short line at inner margin above anal angle. Expanse: 40 mm. Surinam. It is possible that this species is the same as *rhodope*, but for the present I prefer to keep them separate as I have seen no specimens agreeing with STOLL's figure.

C. glaucescens Wkr. (= *margaritacea* Mschlr., *blandatrix* Fldr.) (89 b). Male: More intensely marked *glaucescens*. than *rhodope*, the termen of forewing more oblique, the hindwing longer on inner margin. Female: The markings greyish olive, forming a large antemedial patch at costa and thick double lines below cell; postmedial fascia broad the lines largely suffusing, tinged with cinnamon buff on inner margin; the broad marginal line usually interrupted at vein 5; terminal line broad. Hindwing: a double or a single line not reaching costa tinged with cinnamon at inner margin; a subterminal macular line and sometimes a broken marginal line. Wings below with the markings showing in transparency. Expanse: Male 39 mm; female 50–65 mm. Guatemala; Costa Rica; Colombia; Rio de Janeiro, Brazil.

C. gaudialis Schs. (89 b). Male: Head and thorax white. Abdomen lilacine brown above, white below; *gaudialis*. anal hairs brown. Forewing: basal two-thirds brownish white; the costal margin olivaceous, extending into cell antemedially, interrupted medially by a buff shade, also buff at apex; a silvery white streak on discocellular; a faint ochreous medial shade on inner margin; ochreous shades on veins beyond cell; a silvery white line from costa at three-fourths from base curved to vein 4, and preceded by a broad greyish shade and silvery points on veins, also preceded by grey on inner margin; the outer margin white with a subterminal and a marginal grey shade. Hindwing thinly scaled, white, a dark medial spot on inner margin; reddish-brown shades subterminally at and near inner margin. The cilia ochreous red at anal angle. Expanse: 29 mm. St. Jean, Maroni River, French Guiana.

C. coelestis Schs. (89 b). Male: Legs white shaded with brown. Palpi brown. Head and thorax white; *coelestis*. some brown on frons. Abdomen olivaceous brown above, laterally and underneath white. Wings white opalescent. Forewing: some antemedial and postmedial ochreous spots on costa; a broad subterminal space from vein 4 to costa broken by the veins and divided by a fine white line; a single subterminal spot between veins 2 and 3, these spots are apparently grey but also opalescent in the proper light; a marginal grey shade, not opalescent, cut by the veins, a terminal white line; cilia white outwardly, grey basally. Hindwing: some olivaceous-brown spots on inner margin, a grey spot above anal angle, and some marginal grey spots between angle and vein 4. Female: Wings dirty white. Forewing: a basal space, and two antemedial smoky shades, slightly curved; a geminate postmedial shade curved from costa to vein 4, partly coalescing, followed by a broader similar shade, interrupted between veins 3 and 4. Hindwing as in the male. Expanse: Male 27 mm; female 34 mm. Sixola River, Costa Rica.

C. lilacina Dogn. (89 b). Female: Head and collar white. Thorax vinaceous buff. Abdomen vinaceous *lilacina*. buff above and below, laterally white. Forewing thinly scaled, light brownish drab; costal edge white; termen pale ecru drab beyond a fine outer army brown line, lunular from costa to vein 6, outbent to vein 4, inbent along vein 4, excurved and outbent to vein 3, downbent to vein 2 and slightly inbent below; in places a fine white line precedes this brown line, this latter broader at costa; inner margin light buff; traces of subbasal, antemedial, and medial outcurved lines which are well defined on inner margin; a white spot on discocellular. Hindwing white suffused with pinkish buff on disc to postmedial line and inner margin; from beyond base to postmedial the inner margin is cinnamon brown cut by white lines; postmedial line very faint; a terminal pale smoke-grey shade. Forewing below paler, iridescent, the pattern of upperside visible in transparency. Hindwing below cream colour, the postmedial line with an army-brown spot near inner margin. Expanse: 33 mm. French Guiana.

C. micacea Wkr. (= *albescens* Schs.). Male: White. The abdomen above reddish brown. Forewing: *micacea*. the costa finely light brown; a grey spot on inner margin near base; a small grey spot between veins 2 and 3; an interrupted grey postmedial shade; an interrupted subterminal grey line below vein 4; a marginal grey shade between veins 2 and 7; a terminal fine ochreous line; cilia grey between 2 and 7. Hindwing: inner margin spotted with olivaceous brown; a grey subterminal spot near inner margin; some faint grey marginal spots. Expanse: 22 mm. St. Jean, Maroni River, French Guiana.

C. opalifera Dogn. (= *manni* Schs.) (89 b). Male: Body white: a dark greyish olive spot at base of *opalifera*. abdomen dorsally; anal segment cinnamon. Wings white, thinly scaled. Forewing: a line of silver scales on submedian fold, on discocellular, and on vein 5, not reaching termen, and interrupted by a postmedial square dark greyish olive spot with some black on the vein; costal edge light buff; double greyish olive postmedial marks on costa, the spot on vein 5 sometimes divided; subterminal dark greyish spots, and a broken marginal line. Hindwing: medial and postmedial dark spots on inner margin, and marginal greyish spots from below vein 4 to anal angle. Female: Similar to male. Expanse: Male 24 mm; female 30 mm. French Guiana; Upper Amazons.

umbrata. **C. umbrata** Schs. (89 c). Male: Palpi brown. Head and thorax white. Abdomen pale brown above, white underneath. Wings white. Forewing: the costa finely light brown, a greyish basal shade on inner margin; a greyish medial shade from cell to inner margin; a greyish postmedial shade not extending above vein 5, but continued as two fine brownish lines from vein 4 to costa; an olivaceous spot on the inner line at vein 5; outer margin broadly shaded with grey; a large terminal olivaceous patch from veins 5 to 7; cilia olivaceous. Hindwing shaded with grey below vein 4; the inner margin light brown and olivaceous. Expanse: 23 mm. Amazons.

amoena. **C. amoena** Dogn. (89 c). Male: Frons light buff. Collar white. Thorax buffy olive. Abdomen above tawny olive, laterally and below white. Wings white. Forewing: the lines greyish olive, the costal edge dark olive buff; an outcurved antemedial line followed by a double medial parallel line; a double slightly outcurved postmedial line, closely followed by a short narrow band, and from below 6 by an expanding shade suffusing with a broad terminal shade, this latter also upbent to vein 7 and connected with costa by a fine line. Hindwing: three short lines medially on inner margin and cilia, and some similar darker lines postmedially. Hindwing below with a dark olive elongated spot below vein 2, cut by a fine white line. Expanse: 29 mm. São Paulo de Olivença, Amazons. When faded the markings become paler and more of an olive buff.

similis. **C. similis** Fldr. Male: Body and wings as in *amoena* but the white space on forewing between medial and postmedial lines narrower and the termen with more white above tornus. Expanse: 29 mm. Locality unknown. If FELDER's figure is not correct the species will probably have priority over *amoena*.

klagesi. **C. klagesi** Warr. Female: Forewing: very pale mealy green, thinly scaled and semitransparent, stained with dull rufous olive as far as the submarginal line, which is irregularly waved and lunulate, from costa shortly before apex to anal angle, forming a strong sinus inwards between veins 3 and 4; just before the edge of this stain a slightly darker fascia can be traced, the edges of which are marked with darker on the veins; the marginal area, a narrow costal space, and the discocellular streak remain of the pale greenish ground-colour; cilia pale green slightly mottled with darker; inner margin with darker rufous olive marks. Hindwing: pale green, with the inner margin and a curved submarginal line rufous olive. Underside pale green; the forewings with an opalescent pink sheen beneath the stained area above; hindwings with a double rufous blotch where the submarginal line crosses the submedian fold. Head, shoulders, and patagia pale green; abdomen and tips of patagia rufous olive. Expanse: 30 mm. Suapure, Caura River, Venezuela. This species is unknown to me; the genus *Agriochlora* Warr. has been created for it.

aminula. **C. aminula** Drc. This species is unknown to me. "Forewing and hindwing quite hyaline; the costal, outer, and inner margins and the veins yellow; the base of the costal margin white; the hindwing with a small black spot on the inner margin a little above the anal angle. The head greyish; collar yellow; thorax and abdomen dark reddish brown; antennae and legs yellowish brown. Expanse: $1\frac{1}{4}$ inch. S.E. Brazil. A distinct species, allied to *opalina* Butl."

aerila. **C. aerila** sp. n. (89 c). Female: Head and collar pale drab grey. Thorax and abdomen drab grey. Forewing pale drab grey irrorated with ecru drab and white; costal edge pinkish buff; inner margin pale cinnamon pink; lines light vinaceous cinnamon except those from vein 4 to costa; subbasal, antemedial, and medial lines outcurved; medial space from vein 3 to fold somewhat hyaline and iridescent; lines above vein 4 dark olive buff; postmedial outcurved, lunular, closely followed by a finer parallel line and four small quadrate spots edged with white; some olive yellow before postmedial and between the lines irrorated with golden primrose-yellow scales; below vein 4 the lines are lunular wavy and very fine. Hindwing: costal margin broadly whitish, then light cinnamon drab suffused with fuscous drab on termen; a faint dark medial line; inner margin light ochraceous buff crossed by cinnamon and white lines above anal angle. Hindwing below buff-white irrorated with hair brown on outer half; postmedial hair double, lunular. Expanse: 30–32 mm. São Paulo de Olivença; Upper Amazons. Type in U.S. Nat. Museum Washington. A paratype in STAUDINGER collection from Upper Amazons.

3. Genus: **Arotros** Schs.

Male: Antenna bipectinate to tips. Palpi porrect extending slightly beyond frons, thickly scaled, the third joint almost hidden in hairs. Hind tibia with two pairs of spurs. Forewing broad, the apex and outer margin rounded; vein 2 from beyond middle of cell; 3 near 4; 5 from middle of discocellular; 6–10 stalked; 11 from cell. Hindwing: costa slightly convex; apex and outer margin rounded; vein 2 from middle of cell; 3 and 4 apart; 5 from middle of discocellular; 6 and 7 stalked; 8 anastomosing shortly with cell near base.

Type: *striata* Schs.

striata. **A. striata** Schs. (89 c). Male: Body light ochraceous buff, the collar fuscous shaded in front. Abdomen with fine cinnamon buff lines from base to tip. Forewing light ochraceous buff, the veins and lines on interspaces finely cinnamon buff; base suffused with dark mouse grey, its outer edge inbent from costa before middle to inner margin near base; a faint postmedial cinnamon buff shade. Hindwing light buff; veins and lines on interspaces fainter than on forewing. Expanse: Male 40 mm; female 44–50 mm. Nova Friburgo, Brazil; Tucuman, Argentina.

4. Genus: **Quentalia** *nov. gen.*

Male: Palpi short porrect. Antenna shortly bipectinate. Legs hairy, two spurs on hind tibia. Forewing with apex produced; termen excised below apex, rounded at vein 4 and slightly inbent; vein 2 from just beyond middle of cell; 3 and 4 from lower angle; 5 from middle of discocellular; 6—9 stalked; 10 absent; 11 from cell. Hindwing: costa nearly straight; termen rounded; anal angle rounded or slightly produced; vein 2 beyond middle of cell; 3 and 4 from lower angle, sometimes slightly stalked; 5 from middle of discocellular; 6 and 7 stalked; 8 connected with 7 near base. This genus will contain the many species described under *Carthara* Wkr. which was first used in Cat. Lep. Het. B. M. 33, p. 914 and does not belong to the *Bombycidae*. In Vol. 35, p. 1871 WALKER again used the name *Carthara* for a species of some other family and on page 1984 substituted the name *Synadia* for it.

Genotype: *Pamea vittata* Walk.

Sect. I. Hindwing rounded. Postmedial and subterminal lines of forewing connected between veins 4 and 6 by a triangular spot.

Q. vittata Wkr. (89 c). Male: Head and collar ochraceous salmon, vertex white. Thorax pale pinkish buff crossed by a fine tawny line. Abdomen pinkish buff. Forewing pale pinkish buff; inner margin suffused obliquely to termen at vein 3 with light tawny olive, and similar shading on basal third of costa; an antemedial tawny olive line very oblique from costa and outangled near end of cell closely followed by a wavy medial line; two black points on discocellular; postmedial line tawny olive, oblique, inbent, lunular from vein 4 to inner margin, between veins 4 and 6 followed by an oblique and triangular brownish olive patch; subterminal line white, vertical from costa, inwardly edged with tawny olive, more broadly so distally and extending to apex, below vein 4 the line is tawny olive, lunular and parallel with postmedial; cilia tawny olive. Hindwing cream colour; a broad fuscous fascia from base to termen between veins 4 and 6; fine medial and postmedial wavy lines and cinnamon terminal shading. Forewing below cream colour with dark suffusions beyond postmedial in place of the triangular patch. Hindwing below irrorated with cinnamon, the dark fascia not reaching termen, the lines more heavily marked. Expanse: 31 mm. S. E. Brazil.

Q. orizava Schs. (89 e). Male: Head and thorax pallid mouse grey. Collar light cinnamon drab. Abdomen drab grey. Forewing pale ceru drab, the base suffused with light cinnamon drab; antemedial and medial lines close together, wavy, almost vertical, drab grey; two black points on discocellular; postmedial from a dark costal spot followed between veins 4 and 6 by a benzo-brown quadrate spot; subterminal whitish between 4 and 6, outwardly edged from vein 6 to costa by benzo-brown expanding towards costa; below vein 6 both lines lunular, parallel; cilia at sinus below apex benzo-brown. Hindwing largely colonial buff, the termen broadly drab grey; medial line faint; subterminal fine, distinct, defined by white near inner margin. Forewing below mostly drab, the inner margin whitish. Hindwing below largely suffused with light pinkish cinnamon; a dark line on discocellular; medial line outcurved distinct; postmedial line and termen as above, some dark shading between the lines from vein 2 to near anal fold. Expanse: 33 mm. Orizaba, Mexico.

Q. altura Schs. (89 e). Male: Very much like *orizava*. Body and wings darker, the forewing suffused with brownish, the lines more distinct. Hindwing suffused with vinaceous cinnamon, darkest on termen; the lines fine, and rather faint; inner margin mottled with mikado brown and white hairs. Forewing below with basal half cinnamon buff, outer half sayal brown; inner margin white. Hindwing below cinnamon; a fine black line on discocellular; postmedial and subterminal lines verona brown, connected by a similar shade before inner margin, the subterminal with a white line at outer edge near anal angle. Expanse: 34 mm. Volcan Santa Maria, Purula, Guatemala.

Q. maevia Drc. (= *umbrata* Schs. ♂, nec ♀; = *subrufa* Schs.) (89 d). Male: Body above dark greyish brown mottled with white hairs. Forewing: base and terminal third brownish drab with paler mottlings; medial space clearer, light cinnamon drab; the antemedial and medial line wavy as in previous species; postmedial line well defined, outangled and faintly sinuous, not lunular like the subterminal; the patch between veins 4 and 6 fuscous. Hindwing cinnamon, the disc somewhat yellowish; costal margin cream colour; dark suffusions on inner margin, especially at anal angle; the two outer lines well defined. Forewing below orange cinnamon, the inner margin white; costa yellowish to subterminal, the apex English red; the lines fine, fuscous, outcurved not reaching below vein 2; some white scaling along termen from vein 3 to vein 7. Hindwing below burnt sienna partly mottled with orange rufous; the two lines fine, fuscous, parallel, preceded and followed by some light buffish scaling below vein 2; a fuscous streak from base to termen before anal fold. Expanse: 34 mm. Costa Rica; Chiriqui, Panama.

Q. tolima Dogn. (89 d). Male: Body above brown, varying in intensity. Forewing above very similar to *maevia*, the lines and patch between veins 6 and 8 similar. Hindwing largely cinnamon rufous, the costal margin hardly paler; the lines fine, slightly curved, smooth; some fuscous shading at veins 4—6 between lines, also between lines below vein 2. Forewing below drab, the basal half suffused with vinaceous buff; lines distinct at costa; apex English red; inner margin whitish. Hindwing below burnt sienna; postmedial line smooth,

black, outcurved; outer line finely erenulate, outwardly edged with white; fuscous shading at veins 4—6 between lines, and again below vein 2, this last extending to termen. Expanse: 32 mm. Tolima, Colombia.

subumbrata.

Q. subumbrata Dogn. (89 d). Male: The type very similar to *maevia*, the basal two thirds of forewing more pale buffish, the terminal third cinnamon drab; the postmedial line below vein 4 straight. Hindwing above as in *maevia* with a little less yellow in disc. Forewing below from base to postmedial naphthaleneyellow with a reddish streak below costa and a distinct black line on discocellular; postmedial line outcurved beyond cell, slightly inbent from below vein 4; terminal space orange rufous, thickly irrorated with white except at apex; a burnt sienna terminal line partly edged inwardly with white. Hindwing below as in *maevia*, the basal half and inner margin more vinaceous. Expanse: 36 mm. Colombia. Some specimens have the hindwing largely suffused with pale yellow extending on terminal space.

moratina.

Q. moratina sp. nov. (89 d). Male: Body deep olive buff. Forewing pale olive buff to postmedial; antemedial pale line defined by citrine drab shading on either side; two black points on discocellular; postmedial line dark, sinuous below vein 4, the patch between veins 4 and 6, and towards apex deep olive; subterminal line fine, white, sinuous from costa to vein 4, then lunular; space between lines and termen olivaceous grey. Hindwing pale olive buff on basal half and along costal margin; outer space from below vein 6 olivaceous grey crossed by the parallel lines, the subterminal edged with white near inner margin; anal angle with dark suffusions. Forewing below deep olive buff, thickly irrorated with white hairs; costa and inner margin yellowish white; line on discocellular very faint; postmedial line outcurved beyond cell, smooth, the subterminal faint, outcurved and lunular. Hindwing below deep olive buff; a long dark line on discocellular; lines black, lunular, the space between buffy olive, still darker between veins 4 and 6, and below vein 2 where this colour extends to anal angle; the white line below subterminal very distinct. Expanse: 33 mm. Chiriqui, Panama; Juan Vinas, Costa Rica; Volcan Santa Maria, Guatemala. What I described as *umbrata* ♀ belongs to this species. Type in U.S. Nat. Museum.

melchthala.

Q. melchthala sp. nov. Male: Allied to *moratina* to which it bears a strong resemblance. Forewing similar in colour; antemedial line black, oblique from costa to median, then downbent, sinuous, inwardly edged with white from cell to vein 1; postmedial below vein 4 lunular, but less so than subterminal, the dark spots following it between veins 6 and costa much smaller. Hindwing with the two lines distinctly lunular. Forewing below to postmedial yellowish mottled with dull red, especially below costa; inner margin yellowish white to termen below vein 2; a dark streak on discocellular; postmedial line fuscous, well outcurved beyond cell and crenulate; terminal area dull red, clearer at apex; subterminal line fine, black, crenulate, almost vertical; some white terminally between veins 4 and 5. Hindwing below yellowish thickly irrorated with orange cinnamon hair; a black line on discocellular; the two lines fuscous, conspicuously erenulate, the subterminal with some white edging near inner margin; anal angle suffused with mikado brown. Expanse: 42 mm. Rio Songo, Bolivia; Medina, Colombia; Cachi, Costa Rica. Type in U.S. Nat. Museum.

sheila.

Q. sheila sp. nov. (89 d). Male: Body above cinnamon buff, the collar cinnamon. Forewing light ochraceous buff; antemedial line cinnamon brown, inwardly pale edged, defined by a darker basal shading; a dark medial shade most distinct on costa; an interrupted cinnamon brown line on discocellular; postmedial line broader from costa, outangled at vein 4, slightly incurved to vein 1 and inbent; the patch between veins 4 and 6 orange citrine, also the costal shade edging postmedial line, this line fine, white, with darker edging, lunular from vein 4 to inner margin; space between lines and termen darker shaded, with terminal white shading between veins 4 and 7. Hindwing pale apricot buff, the costal margin and base to postmedial line yellowish, except on inner margin. The lines fine, fuscous, very slightly wavy. Forewing below: costa narrowly, inner margin broadly cream colour; cell and beyond to postmedial peach red mottled with yellowish hairs; postmedial fuscous, thick, slightly outcurved and faintly incurved below vein 4; terminal space, except costa, mottled mars orange and fuscous; faint traces of subterminal line; termen narrowly white opposite cell. Hindwing below light cinnamon rufous; a pale yellowish streak from base and below vein 2; lines black, heavily marked, the subterminal somewhat lunular. Expanse: 34 mm. Merida, Venezuela. Type in U.S. Nat. Museum.

lapana.

Q. lapana Schs. (89 d). Male: Head and thorax light cinnamon drab. Abdomen pinkish cinnamon. Forewing ecru drab, the half below cell and vein 3 suffused with light pinkish cinnamon; antemedial and medial lines faint, wavy; a dark line on discocellular; postmedial line from a small, dark, costal spot, outangled at vein 4, inbent, wavy to inner margin, the quadrate patch olive brown; postmedial line white from costa to vein 4 outwardly edged with sayal brown, below vein 4 dark, fine, lunular; termen narrowly dark brown from apex to vein 4. Hindwing whitish yellow suffused with pinkish cinnamon between veins 4 and 6 from postmedial line to termen, also along termen from apex to anal angle. Forewing below costa narrowly, inner margin broadly pale yellow; otherwise suffused with cinnamon becoming orange cinnamon at apex; some whitish mottling terminally between veins 3 and 5. The lines faintly indicated. Hindwing below pinkish cinnamon; postmedial line orange cinnamon; subterminal line fuscous with some white before inner margin. Expanse: 30 mm. Jalapa, Mexico. The female has the general tone of the male with markings less distinct, the postmedial patch on forewing very faint. Expanse: 42 mm.

Q. lapanensis *sp. nov.* (89 e). Male: Head ochraceous buff, some cinnamon mottling on frons. Collar *lapanensis*. English red tipped with light buff. Thorax dark naphthalene violet shaded in front with light ochraceous buff. Abdomen dorsally dusky drab. Forewing pale ochraceous buff; lines orange cinnamon on costa otherwise dusky avellaneous; antemedial double, wavy, outbent to vein 2, and downbent; black points on discocellular; postmedial line connected with natal brown patch between veins 4 and 6, not interrupted as in the closely allied *lapana*; postmedial fine outwardly edged with light buff and a narrow orange cinnamon shade to vein 6, the last two lines parallel, lunular to inner margin. Hindwing pinkish buff; lines fine, lunular, hair brown; a dark point on discocellular; some mikado brown on inner margin at lines and anal angle; a faint dusky shade from cell to termen between veins 5 and 6. Forewing below as in *lapana*; the hindwing below somewhat paler than in that species, the lines closer together and connected by a fuscous black patch below vein 2, also with white edging below it. Female: Head and thorax brownish drab. Abdomen vinaceous cinnamon. Forewing pale vinaceous drab below cell and vein 3 and beyond cell to postmedial, otherwise buffy brown; antemedial line darker, outangled at median and vein 2 and followed by a duller shade to medial which is outcurved from costa; a dark line on discocellular; postmedial fine outcurved to vein 4, then wavy; whitish to vein 4 followed above vein 6 by some olive brown, below vein 4 deeply lunular; some white scaling on termen between veins 4 and 7. Hindwing orange cinnamon, the lines fuscous, the first faint, the second well defined lunular dentate distally edged with white near inner margin. Forewing below fawn colour, the inner margin white; a dark medial line outbent from costa to inner margin; postmedial line fuscous, wavyly lunular from costa to vein 4, followed to apex by a large apical English red space; some white terminally between veins 4 and 6. Hindwing below: basal half light pinkish cinnamon irrorated with orange cinnamon; a black line on discocellular; postmedial line mikado brown followed by orange cinnamon to outer line, this latter black, lunular outwardly edged with white; termen orange cinnamon with some light greyish scaling on termen between veins 4 and 7. Expanse: Male 28—30 mm; female 47 mm. Male type from the Berlin Museum without locality. Female type from Eastern Colombia.

Q. ojeda *Dogn.* (89 e). Male: Body and forewings pinkish buff (Type) or greyish. Forewing: antemedial *ojeda*. line fine, outangled at median, then vertical; medial diffuse, outcurved; two fuscous points on discocellular; postmedial on costa and outer edging of subterminal from costa to vein 4 Kaiser brown, the quadrate patch argus brown; below vein 4 the postmedial is almost straight, the subterminal faint, lunular. Hindwing light ochraceous buff (Type) or greyish; lines distinct, fine; inner margin with dark and white mottling. Forewing below ochraceous buff, the inner margin whitish; a short dark streak on discocellular; postmedial line clay colour, outbent from costa to vein 4, then incurved; subterminal almost vertical to vein 4, edged on costa with white, below vein 4 slightly incurved. Hindwing below buckthorn brown; a black line on discocellular; postmedial fuscous, outcurved, smooth; subterminal finer, black, outwardly narrowly edged with white, outcurved and faintly lunular; the white below vein 2 broader. Female: Usually greyish avellaneous, the lines darker, all well defined, the shading beyond subterminal from vein 4 to costa much broader. Expanse: Male 29 mm, female 35 mm. Loja, Ecuador.

Q. napima *sp. nov.* (89 e). Male: Wings above similar in colour and markings to *pamina* but larger. *napima*. Forewing below vinaceous cinnamon, the inner margin whitish; apex orange cinnamon; a fuscous patch above vein 6 outwardly edged by a subterminal, black, lunular line, very faint towards vein 2; termen suffused with fuscous, expanding between veins 3 and 6. Hindwing below cinnamon, a pale, fine, smoke grey streak on discocellular edged with black; lines rather close together, black, lunular, the subterminal edged with white near inner margin, the termen below it garnet brown. Expanse: 31 mm. Joinville, S.E. Brazil. Type in U.S. Nat. Museum.

Q. subrubicunda *Dogn.* (89 e). Male: Forewing vinaceous tawny; a reddish shade at base; lines distinct; *subrubicunda*. antemedial and medial outcurved, wavy, parallel; outer lines both wavy below vein 4; subterminal from costa to vein 4 vertical, white; the quadrate patch and outer edging of subterminal walnut brown. Hindwing testaceous, costa whitish; lines faint, the subterminal better defined with black between veins 4 and 6, and with black and white near inner margin; anal angle mars orange. Wings below mars orange. Forewing slightly paler, inner margin whitish yellow; subterminal line fine, black from costa to vein 3; slight dark terminal suffusions. Hindwing: postmedial faint; subterminal black, lunular well defined; a streak of dark mottled scaling before inner margin; black streaks on discocellular of both wings. Expanse: 30 mm. São Paulo, Brazil.

Q. pamina *Schs.* (89 e). Male: Very similar to *lapana*, but smaller. The thorax darker. Forewing *pamina*. differs in having postmedial line from vein 4, inbent, straight, not wavy. Hindwing vinaceous tawny; costal margin paler; lines very faint, better defined between veins 4 and 6; the subterminal edged with white above anal angle; inner margin with mahogany red and white lines, the fold with light buff hairs; anal angle brazil red. Forewing below onion-skin pink, the costa and inner margin whitish, the markings very faint. Hindwing below buff pink; a black streak on discocellular; the lines faint, wavy, well defined with black near inner margin where the subterminal is edged with pale vinaceous pink, and again with black. Female: Body and forewing cinnamon drab; space between antemedial and medial lines, and between postmedial and subterminal from vein 4 to inner margin vinaceous brown. Hindwing dull russet vinaceous, the lines faint. Expanse: Male 25 mm; female 35 mm. Castro, Parana, São Paulo, Brazil.

crenulosa. **Q. crenulosa** Dyar. (89 e). Male: Similar to *lapana*. Forewing: the patch beyond cell very small, sayal brown; outer edge of subterminal towards costa cinnamon, narrow; the postmedial at costa orange cinnamon. Hindwing orange cinnamon; costal margin and hairs along inner margin light buff; lines faint except near inner margin where they are suffused into a fuscous patch. Forewing below tawny; inner margin whitish; costa light buff, not reaching apex with a postmedial and a subterminal small tawny patch. Hindwing below uniform clay colour; the lines black, distinct, connected by a black spot near inner margin; the subterminal faintly edged outwardly with light buff, near inner margin with white. Expanse: 24 mm. Zacualpan, Mexico.

coarya. **Q. coarya** sp. nov. (89 e). Male: Body above vinaceous fawn. Forewing vinaceous buff, suffused on basal third and along inner margin with vinaceous fawn; lines all fawn colour; antemedial and medial lines outbent from costa, slightly inbent below cell, both wavy; a fuscous line on discocellular; postmedial forming a triangular spot on costa, below vein 4, smooth, slightly incurved, the patch between veins 4 and 6 small; subterminal line inbent from costa, fine and lunular below vein 4. Hindwing brownish vinaceous, the outer margin from apex to vein 2 broadly hair brown on interspaces; lines barely visible. Forewing below benzo-brown, the basal third, inner margin, and subterminal line light russet vinaceous; costal margin light pinkish buff. Hindwing below coral pink to medial line; a black line on discocellular; medial line black, well marked, downbent near inner margin; outer half dark brownish vinaceous with some white scales; outer line fine, black, slightly lunular. Expanse: 30 mm. Coary, Amazons, Brazil. Type in U.S. Nat. Museum.

drepanoides. **Q. drepanoides** Wkr. Male: Thorax and forewing vinaceous fawn. Abdomen fawn colour. Forewing with paler suffusions below and beyond cell to postmedial; lines fawn colour; antemedial line bluntly outangled; medial line outcurved; a black line and point on discocellular; postmedial very oblique to vein 4, forming with the incurved white postmedial a large triangle from costa filled in at its apex with chestnut brown, below vein 4 the postmedial is incurved, the subterminal lunular faintly defined by white; the outer edge of subterminal towards costa bordered with chestnut brown. Hindwing ochraceous tawny, darkest on termen; postmedial line faint; subterminal fine, fuscous outwardly edged with white. Hindwing below etruscan red, the lines as above, but connected below vein 2 by a black patch. Expanse: 30 mm. Mexico to Southern Brazil. The above description is made from a Bogota specimen, the locality of WALKERS type, which also has an expanse of 30 mm.

surynorta. The type of — **surynorta** Schs. (89 f) is from Mexico and has the forewing greyer. There are 35 males in the National Museum, and they may represent several species when the genitalia are examined. As yet only a slide has been made of a Mexican typical specimen of *surynorta*.

numalia. **Q. numalia** sp. nov. (89 f). Male: Similar to the greyish form (*surynorta*) of *drepanoides*, but larger, and the genitalia very different. Expanse: 38 mm. Juan Viñas, Costa Rica. Type in U.S. Nat. Museum.

The genitalia differ markedly from those of *drepanoides* in details of the harpe, aedoeagus, and in the shape of the sternite and tergite of the eighth abdominal segment. (In the *Bombycidae* the eighth abdominal segment is highly chitinized, strikingly modified and involved with the genitalia proper.) In *drepanoides* the harpe (or what also might be interpreted as the ventral arm of the harpe) has a long thorn like projection from costa near apex, marking the apex two pronged; while in *numalia* the harpe is simple and bluntly pointed. The aedoeagus is similarly shaped in both species, but in *numalia* the apex is considerably more enlarged. In *numalia* the heavy plate of the sternite is produced caudally into a pair of widely separated, long, slender horns; while in *drepanoides* this part has a central projection which is roughly T shaped, with the base of the T broadened. The tergal plate in *numalia* is produced into a strong, short, broad central hook; in *drepanoides* its caudal margin contains four very stout, evenly spaced spine-like projections. (C. HEINRICH.)

viridans. **Q. viridans** Dogn. (89 f). Male: Head and collar honey yellow; tegulae and abdomen dorsally mottled hair brown and glaucous grey, the abdomen otherwise honey yellow. Forewing: base dark olive buff; end of cell and beyond to postmedial honey yellow, also the inner margin before postmedial; antemedial line hair brown, wavy, and outangled below cell, partly suffusing with a dark olive buff medial line; fuscous points on discocellular; some glaucous grey mottling on basal half of inner margin and medially below cell; postmedial line chestnut brown at costa, vertical to vein 8 well outcurved and inbent to vein 4, then vertical lighter brown to inner margin, followed above vein 6 by a large glaucous grey patch; between 4 and 6 a fawn colour shade; subterminal line lunular from costa to vein 4 outwardly edged with light buff, below vein 4 fine, buffy brown, lunular; space between lines from below vein 4 dark olive buff with glaucous grey irrorations between veins 3 and 4; similar irrorations on the terminal space. Hindwing honey yellow; inner margin chestnut brown crossed by white lines; costa paler; lines barely visible, very fine. Forewing below ceru olive; lines fine, fuscous; a line on discocellular; postmedial slightly outcurved from costa; subterminal slightly lunular. Hindwing below chamois; a black line on discocellular with some white on edge; lines olive brown, the postmedial faint, the subterminal lunular well marked, outwardly edged with white. Expanse: 32 mm. Rio Songo, Bolivia.

pallida. **Q. pallida** Maass. Male: Body and wings light buff. Forewing: subbasal and medial lines light ochraceous buff, diffuse, outcurved. Antemedial line, fine, more distinct, angled at median; postmedial outbent, fuscous,

postmedial almost vertical from costa finely defined by fuscous, both lines lunular and parallel from vein 4 to inner margin; the small patch between veins 4 and 6 dark or obsolete, two black points on discocellular; terminal space from postmedial below vein 4 to tornus and beyond subterminal from vein 4 to apex suffused with dark olive buff. Hindwing: the lines fuscous finely wavy, lunular, and distinct. Forewing below warm buff; a faint dark line on discocellular; the outer lines fuscous, partly lunular. Hindwing below largely suffused with cinnamon buff; a black line on discocellular; the two lines fuscous, distinct, lunular, sometimes with a fuscous shade between veins 4 and 6. Expanse: 33—42 mm. Peru; Loja, Ecuador.

Q. paminella Dogn. (89 f). Male: Head and part of collar light ochraceous buff. Thorax cinnamon drab, *paminella*. Abdomen reddish cinnamon. Forewing vinaceous brown; a medial and a postmedial ochraceous buff streak on costa; costa, cell, and beyond to postmedial line light russet vinaceous limited below by a vinaceous grey line from base of inner margin upcurved to subterminal at vein 4; a dark antemedial and medial, outbent to below cell, then vertical; a sinuous black line on discocellular; a dark postmedial line outangled at vein 4, then slightly inbent, straight; the patch and broad outer shade of subterminal suffusing, maroon indistinctly edged with black; the costal space above patch light drab; postmedial line white at costal edge, then very faint to vein 6 and outbent, still fainter to vein 4, below 4 defined by light buffish points on veins; termen from apex to vein 4 light vinaceous drab. Hindwing ochraceous tawny; postmedial line very faint, the subterminal fuscous partly defined by whitish near inner margin; anal angle burnt sienna. Hindwing below with the lines well defined, fuscous, the subterminal outwardly edged throughout with white; a large fuscous patch between the lines near inner angle. Expanse: 30 mm. Medina, Colombia.

Q. incurvata Dogn. (89 f). Male: Head and body deep brownish vinaceous. Forewing vinaceous *incurvata*. cinnamon, paler beyond cell to postmedial and below the lines at vein 4 to near termen; a darker medial shade outangled below median; two black spots edged with whitish on discocellular; postmedial very oblique to near termen at vein 4, the patch small, maroon; subterminal fine, white, incurved, and outbent, broadly edged outwardly with maroon and black to close to apex on costa; below 4 the line is extremely fine and faint with pale dark edged points on veins. Hindwing cinnamon, the lines not visible; cilia tipped with dark livid brown at anal angle. Wings below vinaceous tawny. Forewing: inner margin pale vinaceous; some whitish marks on costa at lines, these latter very faint. Hindwing: the lines fine and well defined fuscous, the subterminal wavy lunular outwardly edged with white; a slightly darker shade between the lines towards inner margin. Expanse: 34 mm. Peru.

Q. oaxacana Schs. (89 f). Female: Body pale ochraceous buff. Forewing light buff; tornal area to *oaxacana*. vein 3 and obliquely from middle of wing suffused with greyish buff; a diffuse medial deep olive shade outangled below cell; two dark points on discocellular; postmedial line brownish grey very oblique to vein 4 and subterminal close to termen, the subterminal whitish, incurved, and oblique, the space between with avellaneous and light drab suffusions, but no distinct patch between veins 4 and 6; subterminal from vein 6 to apex outwardly followed broadly by sayal brown and yellow ocher. Hindwing ochraceous buff with some greyish shading, especially between the lines between veins 4 and 6, and below vein 2; the postmedial very faint, the subterminal defined by distal white edging; termen from vein 2 to inner margin drab. Forewing below largely isabella colour, the inner margin whitish, also termen narrowly from vein 3 to apex. Hindwing below honey yellow; a fine line on discocellular; postmedial line isabella colour, the subterminal drab with white edging from vein 2 to inner margin; dark shading below vein 2 from postmedial to termen. Expanse: Male 37 mm; female 35—42 mm. Oaxaca, Mexico. Cocoons found on bark of trees; they are long and thickly woven.

Q. dolorosa Jones. (89 f). Female: Head and thorax ecru drab, the collar fuscous in front. Abdomen *dolorosa*. light cinnamon drab. Forewing pale ecru drab irrorated with hair brown, the lines fine drab; antemedial and medial lines outcurved; an interrupted streak on discocellular; postmedial line outbent and sharply angled at vein 4, then incurved; postmedial only slightly outbent, curved and inbent. Hindwing drab with buffish shading at base; the first line medial, the second postmedial, faint, hair brown, the postmedial with a little white on outer edge near inner margin. Forewing below about the same as above, but postmedial line very faint. Hindwing below pale vinaceous buff irrorated with hair brown; both lines fine, distinct. Expanse: 31 mm. Castro, Parana, Brazil.

Q. minasa sp. nov. (89 f). Female: Head and front of collar light buff, remainder of collar and thorax *minasa*. dark purple drab. Abdomen above with alternating fuscous and buffy brown lines. Forewing falcate, light purplish grey; costal edge to just beyond postmedial cinnamon; cell, inner margin narrowly, antemedial and vein 3 to outer line black, conspicuous; postmedial outbent benzo-brown suffusing with a similar shade between medial shades benzo-brown; discocellular, a line on vein 2 and veins 4 and 6; postmedial line light buff slightly outbent and curved at vein 4, then more faintly marked, wavy; median and veins 4, 6, 7 beyond postmedial mottled with buff; a benzo-brown shade beyond postmedial from vein 4 to costa; cilia on sinus

below apex fuscous. Hindwing brown, the costal margin and veins cinnamon brown. Forewing below hair brown, the termen suffused with drab grey. Hindwing below mottled cinnamon drab and deep mouse grey partly irrorated with whitish; the lines dark, fine, the outer line wavy partly edged with white distally. Expanse: 34 mm. Passa Quatro, Minas, Brazil. Type in coll. W. HOPP-Charlottenburg.

granisca. **Q. granisca** Schs. (89 g). Female: Head: frons dark purple; vertex brown mottled with white hairs; palpi brown tipped with yellow. Thorax light reddish brown, the collar and tegulae dark purple with some white hairs. Abdomen above reddish brown, underneath paler. Forewings purplish brown; base mottled with olive yellow, except around purple spot; first antemedial line fuscous, outcurved to vein 2, slightly incurved below it; second line less curved, and not so distinct; medial space narrow, paler, but broadened beyond cell; two black points on discocellular; postmedial line outbent to vein 4, then inbent along this vein to lower discocellular point below which the line is almost straight to inner margin; outer line remote on costa, somewhat lunular and slightly oblique to vein 4 then deeply lunular to inner margin outwardly finely edged with whitish especially on costa; termen broadly lilacine from vein 4 to costa leaving a brown shade beyond the outer line. Hindwings brownish red; postmedial line fine, black, hardly visible; outer line indistinct, but thickening to black shades between veins 4 and 6 and below vein 2 to postmedial; a distinct white line outwardly runs along this last black shade and is upbent to inner margin at postmedial line. Forewings below dull purplish, the termen shaded with red, the inner margin pale reddish. Hindwings below dark brownish red; a black line on discocellular; postmedial fuscous surmounted by white scaling on a dark streak below vein 2; postmedial line fuscous, with some white scaling between veins 4 and 6, and a distinct white line from vein 2 to inner margin; some white irrorations at anal angle. Expanse: 55 mm. Purula, Guatemala.

purulhana. **Q. purulhana** Schs. (89 g). Female: Palpi reddish; frons purple brown. Collar reddish brown. Thorax and abdomen above dark slate mottled with white hairs. Body below pale reddish brown. Forewings dark slate colour, the veins, costa, and inner margin finely reddish brown; base of inner margin yellowish; a fine fuscous streak on discocellular followed by a greenish yellow shade between veins 4 and 6; the geminate antemedial line hardly visible; a fine postmedial dark line outcurved around the yellow postdiscal shade, geminate, and hardly visible below vein 4; the outer portion of line reddish brown from vein 4 to costa edged on either side with greenish yellow; cilia purple brown, shaded with black toward apex. Hindwings slate colour, the veins, cell, and interspaces near cell between veins 2 and 4 pale reddish; a dark grey streak from base to termen below cell and vein 2; a dark red brown streak along inner margin with the cilia mottled black and white; cilia on termen black tipped with yellow. Hindwings below purple brown; a yellowish medial shade; a yellow streak below cell and vein 2; first outer line almost medial, dark, well defined, the second line fine and indistinct; a dark red brown shade at anal angle. Expanse: 43 mm. Purula, Guatemala.

tremulans. **Q. tremulans** Schs. (89 g). Male: Head and thorax buff. Collar and abdomen light reddish brown. Forewings reddish brown mottled with yellow scales, except on base; first antemedial line inwardly edged with yellow, the second line darker, ill defined; postmedial line darker outcurved on costa, wavy below vein 4; a subterminal yellow line, almost straight to vein 4; then slightly lunular to tornus its inner edge faintly dark shaded; termen shaded with grey from apex to just below vein 3. Hindwings pale reddish; the outer line fuscous, finely wavy, outwardly edged with yellow; a faint yellow shade at end of cell; a dark reddish brown shade at anal angle; hairs on inner margin yellow spotted with brown. Forewings below red, the apex broadly shaded with fuscous grey, crossed by a subapical whitish line, the inner margin yellow. Hindwings below red shaded and irrorated with yellow; postmedial line reddish; outer line fuscous, outwardly edged with yellow becoming white near inner margin and there crossing a dark shade from anal angle to postmedial line; a fine red streak on discocellular. Expanse: 28 mm. Jalapa, Mexico.

demerida. **Q. demerida** Schs. (89 g). Male: Head rufous shading to white on vertex; shaft of antennae white, the pectinations brown streaked with white close to shaft. Collar dark rufous. Thorax pale rufous brown mottled with white hairs. Abdomen pale rufous, with small dark brown subdorsal spots on basal segments. Forewings light ochre buff, with rufous irrorations; a white streak on costa at base, followed by antemedial and medial dark reddish brown streaks separated by white scaling, and a smaller dark spot postmedially; lines very fine, darker, almost imperceptible, the antemedial geminate, slightly outcurved across cell, the postmedial geminate, wavily lunular; a fine dark streak across discocellular, cilia dark brown. Hindwing pale rufous, dark streaks on inner margin; dark rufous shading at anal angle. Forewings below rufous darkest at apex, the inner margin yellow; costa yellowish, the dark spots very small; some whitish shading at middle of outer margin. Hindwings below rufous, the costa shaded with dark grey; a black streak on discocellular; a lunular, geminate postmedial fine black line terminating at a dark streak before inner margin which extends to termen; a small white spot on outer edge of the line adjoining the dark streak. Female: Body and wings yellowish buff. Forewings: the lines more distinct filled in with a slightly darker shade, the postmedial marked with minute rufous spots on costa; some whitish shading at middle of outer margin. Hindwings slightly tinged with rufous; an antemedial rufous spot on inner margin; a postmedial geminate line as on forewing, but less lunular. Wings below yellowish

buff, the hindwings with a geminate postmedial dark line, outcurved, the two lines almost meeting on inner margin where they are shaded with lilacine white; a dark shade on termen at anal angle. Expanse: Male 32 mm; female 40 mm. Volcan de Santa Maria, Guatemala.

Q. intranea *Dogn.* (89 g). Male: Head avellaneous. Collar and thorax mottled clay colour and pinkish cinnamon with some white hairs. Abdomen pinkish buff, with chestnut brown dorsal tufts on basal half. Forewing: base tawny mottled with rufous on costa, and some benzo brown and white scales on base of median; traces of an antemedial rufous line; cell and beyond to postmedial light buff faintly suffused with pale olive; a fine medial line, rufous from costa to median, then fuscous and double to inner margin; two black points on discocellular; postmedial line inbent from costa, slightly sinuous, tawny; subterminal parallel with postmedial, lunular, fuscous outwardly edged with white; space between lines partly cinnamon, between veins 4 and 6 irrorated with fuscous; termen cinnamon, darker on sinus below apex, towards inner margin partly cream colour. Hindwing cream colour; a black discal spot; inner margin narrowly ferruginous; postmedial line pale tawny, distinct; subterminal faint and very fine and lunular; an orange cinnamon space at anal angle. Wings below cream colour; forewing with a cinnamon shade below costa at base; discal spot on hindwing black, well defined, the subterminal line better defined than above and with a dark spot near inner margin, and sometimes another near anal angle. Expanse: 30—40 mm. Cali, Colombia. *intranea.*

Q. lividia *Dre.* (89 g). Male: Head and body extremely variable through all shades of grey and brown. the abdomen with or without darker, transverse lines, sometimes interrupted by a pale dorsal line. Forewing usually light buff or whitish, the base and termen with cinnamon mottling; antemedial and medial lines cinnamon, parallel, bluntly outbent at median and incurved to vein 1; a fine dark line on discocellular; postmedial from a cinnamon spot on costa outcurved to vein 5, but usually interrupted to that point, where it is close to the subterminal which is slightly lunular from costa; below vein 5 both lines are parallel and deeply lunular, sayal brown; space between lines benzo-brown, drab grey, or light cinnamon drab; the termen is also variable. Hindwing hair brown, cinnamon drab or vinaceous cinnamon, frequently only the basal half suffused with ochraceous tawny. Female: Body and forewing hair brown or cinnamon drab, the subterminal line outwardly edged with cinnamon brown from vein 4 to costa; hindwing usually benzo-brown. Expanse: Male 31—39 mm; female 45—53 mm. Mexico to Colombia, Venezuela, Amazons, Peru. Of the 35 males in the National Museum, genitalia slides have been made of the more variable forms showing them to belong to one species. *lividia.*

Sect. II. Forewing denticulate.

Q. denticulata *Schs.* (89 g). Male: Frons light brown. Vertex fuscous brown. Collar brown. Thorax grey-brown; fuscous shadings on patagia. Abdomen dark ochreous brown. White irrorations on vertex and patagia. Forewings dull greyish brown, with a few scattered white scales; the costa, inner margin narrowly, and veins ochreous brown; the lines dark brown except on costa where they are reddish; the medial sinuous; the postmedial almost coalescing with medial at vein 2 and on inner margin; the outer line dentate lunular; the outer margin produced at veins 3 and 4; cilia ochreous brown, tipped with white between 3 and 4, and 5 and 7. Hindwings broadly fuscous brown on costal and outer margins; from base and vein 4 to inner margin a large yellowish space shaded with brown and crossed by reddish; finely dentate postmedial and outer lines, the latter outwardly shaded with yellowish white; the termen crenulate from vein 4 to anal angle. Forewings below brownish; the inner margin luteous; the costa ochreous yellow irrorated with red, and with origin of lines red; terminal interspaces fuscous. Hindwings below fuscous brown with a few white irrorations; the lines reddish, outwardly whitish shaded on inner half; some reddish and yellow suffusions below cell and vein 4 to inner margin. Expanse: 28 mm. Tuis, Costa Rica. *denticulata.*

Q. excisa *Maass.* (89 g). Male: Frons russet. Collar brownish drab. Thorax and abdomen dorsally deep brownish drab, abdomen laterally fawn colour. Forewing: costal margin clay colour; base to postmedial tawny olive with benzo-brown suffusions antemedially above inner margin; faint traces of an outangled medial line; two black points on discocellular; postmedial outcurved, subterminal sinuous, both very faint, fuscous; termen from postmedial to just above vein 6 benzo-brown. Hindwing benzo-brown, the disc and inner margin suffused with pinkish cinnamon; lines very faint, the subterminal defined with white near inner margin, which is narrowly streaked with fuscous. Forewing below saccardo's umber, the costa clay colour; a faint trace of postmedial line. Hindwing below pecan brown; a black line on discocellular; postmedial line wavy, fuscous, the subterminal tawny, both marked with English red near inner margin where the subterminal is also edged with white. Female: Body and wings vinaceous buff or drab, the termen more narrowly benzo-brown; the lines well defined, the medial double. Expanse Male: 30 mm; female 34 mm. Incachaca, Bolivia; San Antonio, Colombia. *excisa.*

Sect. III. The following species have the discal spot on underside of hindwing white.

Q. roseilinea *Schs.* (= *secata* *Dogn.*) (89 h). Male: Forewing light brownish drab, the lines partly deep brownish drab; a pale pinkish line from base along median and veins 3 and 4 to termen, the space between these veins pallid, mouse grey; the lines across wing interrupted by the pinkish line; a subbasal line: antemedial *roseilinea.*

and medial lines outbent on costa and cell; postmedial outbent, the patch beyond and outer shading of subterminal tinged with dark olivaceous; subterminal fine, white to vein 3, slightly outbent; both lines inset, vertical, wavy, dark below vein 3; termen narrowly white from apex to vein 3. Hindwing dull cinnamon drab, costa whitish; a hair brown fascia from discocellular to termen between veins 4 and 6; postmedial line indistinct; subterminal line fine, fuscous, outwardly whitish between 4 and 6, and below vein 2. Forewing below benzo-brown, the inner margin whitish, the costa light buff; lines very faint; termen irrorated with white from near apex to vein 2. Hindwing below benzo-brown; inner margin and termen partly drab grey; a white streak on discocellular; lines fuscous outcurved, downbent above anal angle and connected by black scaling. Expanse: 30 mm. Castro, Parana, Brazil. The type of *secata* and a specimen from São Paulo have the hindwing partly russet vinaceous.

secalina. **Q. secatina** *sp. nov.* (89 h). A series of specimens from Peru and Colombia including a specimen labelled *secata* (co-type) differ in the following respect. Male: Forewing: base cinnamon; medial space clay colour; space between veins 3 and 4, and termen partly drab grey; antemedial, medial, and postmedial lines mikado brown, the latter outbent to vein 4, then slightly inbent; the patch between 4 and 6 sayal brown; postmedial line cinnamon buff, below vein 4 lunular, darker edged inwardly, the subcostal patch mahogany red. Hindwing light orange cinnamon; lines fuscous, connected by darker shades between veins 4 and 6, and below vein 2, the subterminal partly edged outwardly with white. Forewing below cinnamon, the lines fuscous almost vertical; inner margin light vinaceous cinnamon; termen with lilacine shading. Hindwing below orange cinnamon; a white streak on discocellular; postmedial mikado brown; subterminal black, well edged outwardly with white. Expanse: 32 mm. Carabaya, Peru (Type); Pacho, Colombia. The Colombian specimens are not so vivid.

macerina. **Q. macerina** *sp. nov.* (89 h). Male: Frons ochraceous buff; vertex whitish; collar pinkish cinnamon in front, then sayal brown tipped behind with white. Thorax drab grey. Abdomen cinnamon buff. Forewing: base citrine drab crossed by darker basal, subbasal, antemedial, and medial lines, the antemedial fine and well defined, fuscous, the medial diffuse outangled below cell at vein 3; space beyond to postmedial avellaneous; postmedial sayal brown outcurved from costa, below vein 4 hair brown nearly straight; space between lines buffish on costa, the patch benzo-brown, below vein 4 to inner margin citrine drab; postmedial line white, very faintly outcurved, more vertical than in any other species of the genus, below vein 4 lunular; termen largely suffused with citrine drab below vein 4; a terminal white line from vein 4 to apex, expanding to postmedial line at vein 5. Hindwing mostly cinnamon buff; a mikado brown fascia from base to subterminal line between veins 4 and 6; postmedial line dark, the subterminal broadly edged with white and down angled above anal angle. Forewing below dark olive buff, inner margin whitish; lines dark, faint; terminal white markings as above. Hindwing below cinnamon buff irrorated with white hairs; the fascia of above fuscous, from near base, on its upper edge a small black and white spot; postmedial line sayal brown lunular dentate; subterminal line lunular from below vein 6 outwardly edged with white. Expanse: 29 mm. A specimen without locality received from the Berlin Museum.

callinicia. **Q. callinicia** *sp. nov.* (89 h). Male: Body avellaneous. Forewing; some black and white scales at base of costa; costal margin to subterminal, base and space below cell clay colour, except a light drab streak above vein 1; a snuff-brown streak at cell; a black line on discocellular surrounded with some light drab scaling; space between veins 2 and 4 drab grey, between 6 and 7 fuscous with some white scales; postmedial sayal brown, outcurved and suffusing with the sayal space between veins 4 and 6, below 6 faint and slightly inbent; subterminal distinct, incurved and outbent, rounded at vein 4 near termen, and sinuous to inner margin, white to vein 3, then hair brown edged outwardly with mikado brown which expands to costa, between veins 3 and 1 followed by a cinnamon shade. Hindwing dull, pinkish cinnamon with a dark fascia from within cell and between veins 4 and 6 to termen; postmedial line very faint; subterminal line black, coarse, outwardly edged with white below vein 2. Forewing below light cinnamon drab, darker towards termen, the inner margin paler; lines sinuous, very faint. Hindwing below buckthorn brown with some warm buff mottling; a white line on discocellular; lines fuscous, both well outcurved; the postmedial faint, the subterminal partly edged with white; a fuscous patch below vein 2 with an inbent branch. Expanse: 29 mm. Brazil. Described from a specimen in the Berlin Museum.

caulea. **Q. caulea** *sp. nov.* (89 h). Male: Head buffish. Collar and thorax tawny olive. Abdomen light greyish buff. Forewing: base pale olive lake with some white scales before antemedial line; the antemedial benzo-brown wavy, outbent, angled at vein 2, inangled on fold and again outangled on vein 1, followed by a fainter paler parallel line, more distinct from vein 2 to inner margin; cell and beyond to postmedial olive lake; a black line on discocellular; costal margin medially white; postmedial line benzo-brown outbent to vein 4 followed by a benzo-brown patch between 4 and 6, faint to vein 3 then distinct and vertical to inner margin; space between veins 3 and 4 between lines pale drab grey irrorated with white; postmedial line fine, white, lunular inwardly edged with black inwardly and followed at costa by a brownish olive spot; termen white suffused with glaucous grey from vein 4 to apex; from vein 4 to inner margin a subterminal broken, olive lake shade. Hindwing drab grey, the costa white, the termen broadly buffish; a wavy fuscous outer line; inner margin light buff with

transverse black and cinnamon lines; anal angle cinnamon. Forewing below drab, the inner margin white. Hindwing below drab; the termen paler; a black and white spot on discocellular; first line buffy brown, second line fuscous, lunular, the lines connected by a fuscous black spot near inner margin with some white scaling above and below it. Expanse: 24 mm. Passa Quatro, Minas, Brazil.

Q. ragna *sp. nov.* (89 h). Male: Body light drab; vertex whitish; frons, collar in front and abdomen dorsally sayal brown. Forewing greyish avellancous, the lines and discocellular spots cinnamon drab; antemedial and medial lines outcurved, wavy; postmedial line well outbent and curved, inbent from vein 4, faintly sinuous; subterminal line benzo-brown, lunular, outwardly edged with whitish scales, followed from costa to vein 6, and from vein 4 to inner margin by some pinkish cinnamon shading; some drab and cinnamon shading between veins 4 and 6; cilia pinkish cinnamon. Hindwing light drab on interspaces, the veins and termen narrowly vinaceous cinnamon; lines very faint, the subterminal distally edged with white near inner margin. Forewing below vinaceous cinnamon dark shaded at apex, the inner margin whitish. Hindwing below dull cinnamon buff; a black and white spot on discocellular; lines fine, distinct, wavily dentate connected by a verona brown patch near inner margin, with white scaling above postmedial and outwardly on subterminal. Female: Thorax light drab. Abdomen avellancous. Forewing: base and space between antemedial and medial lines dull cinnamon drab, the two lines slightly darker, parallel angled on median between veins 2 and 3, and inbent; space to postmedial prominently ecru drab; dark points on discocellular; postmedial line hair brown, outangled at vein 4 and inbent; subterminal hair brown outwardly slightly edged with pale drab grey, incurved, remote from origin of postmedial, the triangular space from costa to vein 4 between the lines buffy brown; below vein 4 the subterminal lunular, the space between the lines to inner margin drab; subterminal followed from costa by sudan brown, broadly on costa, then diminishing; termen between apex and vein 4 pale drab grey. Hindwing as in male, but duller. Forewing below drab with faint traces of outer lines. Hindwing below light cinnamon drab, the lines fuscous, distinct; a black streak with a few white scales on discocellular. Expanse: Male 28 mm; female 31 mm. Passa Quatro, Minas, Brazil. Type in the Berlin Museum.

Q. medinara *sp. nov.* (89 h). Male: The wings above like *lapana*. Forewing below also similar. Hindwing below differs in having a broad white line edged with fuscous on discocellular. Expanse: 25 mm. Medina, Colombia. Type in U. S. Nat. Museum.

Q. punctilinea *Dogn.* (89 h). Male: Head light ochraceous buff. Collar and tegulae ochraceous tawny. Thorax drab. Abdomen russet, the basal segment liver brown. Forewing: space below cell to terminal points drab mottled with cinnamon rufous forming lines and a broad medial band separated by some buffish scaling; costa with basal third ochraceous buff, medial third light buff, apical third partly light drab; cell cinnamon rufous; a buff line on discocellular with fuscous point at lower angle; space from cell to postmedial light greyish olive; space between veins 3 and 4 to subterminal pale violet plumbeous, also between 2 and 3 from cell to postmedial; postmedial, quadrate spot, and outer edging of subterminal fuscous, the enclosed space above vein 6 between lines fuscous irrorated with pale violet plumbeous; postmedial outbent to vein 4 fuscous, from vein 3 to inner margin inbent; postmedial slightly incurved from costa to vein 6 lilac grey then to vein 4 naples yellow followed by a broad naples-yellow shade not reaching termen; from vein 3 to inner margin with cream colour streaks on veins; termen between 4 and 7 narrowly lilac grey, below vein 4 hair brown; cilia mostly fuscous with a whitish line at base. Hindwing chiefly deep purplish grey, the inner margin mottled with fuscous and sudan brown (Type), sometimes with morocco red; lines rather faint, the postmedial diffuse black, the subterminal defined by some pale scaling. Forewing below hair brown, inner margin with white hairs; lines between 4 and 7 defined, followed by the same colours as above. Hindwing below benzo-brown; a well marked white spot on discocellular; a broad cream colour streak medially near inner margin; the lines faint, the subterminal defined by faint white scaling, and a cream colour spot near inner margin. Expanse: 33 mm. Rio Songo, Bolivia.

Sect. IV. Wings broader, the forewing more deeply excised below apex.

Q. veca *Dre.* (89 h). Male: Head cinnamon. Thorax vinaceous drab. Abdomen cinnamon with dark greyish brown dorsal crests. Forewing nearest vinaceous fawn tinged with pale purplish brown, the lines snuff brown; antemedial outangled on median inwardly edged with whitish and some brown basad; medial line fuscous on costa and discocellular, then paler, inbent; postmedial outcurved to a small fuscous spot between veins 4 and 6; subterminal pinkish buff, sinuous to vein 4, outwardly followed below costa by some Hay's russet, below vein 4 both lines sinuous to inner margin; a curved shade on termen from vein 3 to tornus. Hindwing cinnamon rufous; inner margin mottled with fuscous, at angle with Hay's russet; lines very faint, the subterminal with some white near inner margin. Wings below largely cinnamon rufous. Forewing with inner margin buffish. Hindwing: a black and white streak on discocellular; the lines faint, becoming fuscous and downbent near inner margin with some whitish scaling. Female: Forewing light cinnamon drab; inner lines very faint; a dark line on discocellular; postmedial outcurved to vein 4 then lunular; subterminal pinkish buff; straighter than in the male, outwardly edged with fuscous to vein 4, then lunular, parallel with postmedial. Forewing below drab; hindwing below cinnamon rufous; the lines and discal spot as in male. Expanse: Male 26 mm; female 38 mm. Panama; Costa Rica.

chromana.

Q. chromana *sp. nov.* (89 i). Male: Head and front of collar cinnamon brown. Thorax Prout's brown irrorated with pale silvery blue hairs. Abdomen chestnut. Forewing benzo-brown thinly irrorated with pale silvery blue scales, the lines verona brown placed as in *veca*; subterminal line fuscous suffusing with fuscous shading between veins 4 and 6; the space between veins 3 and 4 sometimes light greyish olive; termen largely greyish olive partly edged by a submarginal fuscous line below vein 4 and costa. Hindwing silky benzo-brown, the costa pale drab grey; termen narrowly and inner margin more broadly Sanford's brown. The lines black, very faint. Forewing below hair brown, the costa and apex English red. Hindwing below dull English red, brightest on termen; a small black and white discal spot; lines fine, black, with some white on subterminal near inner margin; a raw-umber shade at anal angle. Female very similar to *veca*, but darker and with scattered pale silvery blue scales. Expanse: Male 29 mm; female 37 mm. Tuis, Costa Rica; Chiriqui, Panama.

amisena.

Q. amisena *Drc.* "Male: Primaries dull brown, crossed by three waved darker brown lines, and close to the apex an elongated reddish-brown spot. Secondaries brown, with three short white streaks along the inner margin. The head, thorax, and abdomen yellowish brown; antennae dark brown. The female is considerably larger and much darker in colour, the primaries being much irrorated with grey scales; the secondaries are also blacker. Expanse: Male $1\frac{3}{4}$ inch.; female 2 inches. Ecuador, Sarayacu (Buckley, Mus. Druce). A very distinct species, allied to *veca*, from the Volcan de Chiriqui." This species is unknown to me.

reissi.

Q. reissi *Maass.* Male: Only known to me by the figure in STÜBEL Reise. Forewing drab grey with lines as in *veca*. The underside of hindwing shows a black point without any white. Similar in size to *veca*. Colombia.

figus.

Q. figus *H.-S.* (= *cachiana* *Schs.*) (89 i). Female: Head, collar, and thorax greenish buff. Abdomen ochreous; a dark grey dorsal line and transverse black band on basal segment. Forewings: basal third greenish buff, limited by the inner line, which is whitish, finely edged with fuscous grey, oblique to median between veins 2 and 3, angled and inwardly oblique; space to outer line greyish, tinged with green on costa, crossed by a medial and a postmedial fuscous shade; the outer line whitish, tinged with lilacine, straight to vein 4, then slightly inbent and faintly lunular between veins; the outer margin greenish from vein 5 to costa, below 5 silvery grey, leaving a greenish shade along outer line from 3 to inner margin; a subterminal brownish shade from 5 to 7; veins 5—7 terminally brownish. Hindwings dull greenish buff; the inner margin dark olive-green, crossed by a white antemedial line, and a downbent semioval white line postmedially; a fuscous postmedial shade followed by lilacine shading from vein 2 to inner margin; the outer line lilacine white, edged with fuscous, terminating at anal angle, which is considerably produced. Wings below greenish ochre, the apical area of forewings and outer margin of hindwings brighter; a fuscous postmedial line; the outer line whitish; a white discal spot on hindwings. The line on underside of hindwings is more like the line on the species of *Anticla*. Expanse: 57 mm. Cachi, Costa Rica.

5. Genus: **Anticla** *Wkr.*

Palpi slender, smoothly scaled, upturned to frons. Antenna bipectinate. Legs moderately hairy. Forewing: costa slightly curved, apex acute; termen nearly straight; vein 2 from middle of cell; 3 and 4 from lower angle; 5 from middle of discocellular; 6—9 stalked; 10 absent; 11 from cell. Hindwing: termen rounded; inner margin somewhat prolonged, the anal angle slightly produced; vein 2 from beyond middle of cell; 3 and 4 stalked; 5 from middle of discocellular; 6 and 7 well stalked; 8 and 7 connected near base.

Type: *A. antica* *Wkr.*

flavaria.

A. flavaria *Cr.* (= *flavifuscula* *Hbn.*) (89 i). Male: Body and forewing pinkish buff. Forewing: fine darker antemedial, medial, and double postmedial lines, the first two wavy, the last lunular followed on costa by a large saccardo's olive spot reaching vein 6 and edged with whitish; postmedial line below vein 3 filled in with tawny olive, and a similar broad terminal shade; a dark point on discocellular. Hindwing pinkish buff, the costa suffused with cream colour, the termen with light vinaceous cinnamon; cilia drab tipped with white; double olive brown lines on inner margin. Forewing below antimony yellow; costa and apex broadly ochraceous salmon preceded by a dark olive grey shade. Hindwing below drab grey to outer line; some warm buff shading from base to postmedial line below cell; termen mostly antimony yellow; the postmedial line faint, the outer line fine, hair brown downbent to inner margin above angle. Female: Forewing isabella colour suffused with purplish; base antimony yellow, also the costa expanding before apex and on terminal space at postmedial line from vein 4 to vein 1; the lines as in male; a dark point on discocellular; cilia white at base on interspaces. Hindwing deep chrome, the inner margin and anal angle brownish drab cut by white lines; transverse lines faint. Wings below deep chrome, the lines fine, benzo-brown well marked. Forewing: a large purplish triangular space on termen, hindwing with a similar shade at anal angle. Expanse: Male 28 mm; female 34 mm. French Guiana; Amazons.

A. antica Wkr. (= *rutula* Drc., *carya* Drc., *amycla* Drc.) (89 i). Male: Very similar to *flavaria*. Forewing *antica*. with the costal spot smaller, and forming two spots one above and one below vein 7. The colour varies from pale drab grey to avellaneous and light buff. Postmedial line usually filled with darker colours below vein 4. Female: Also very similar to that sex of *flavaria* but the base of cilia on interspaces is never white. Expanse: Male 24 mm (average); female 34—40 mm. Costa Rica; Panama; Colombia; Venezuela.

A. ortygia Drc. (= *ampea* Drc.) (89 k). Male: Forewing acute, slightly falcate; veins 3 and 4 on hindwing *ortygia*. sometimes from angle. Forewing pale vinaceous fawn or pinkish buff suffused below cell with pinkish cinnamon; lines dark and very similar to *antica*; a black point or line on discocellular; dark triangular shading on termen opposite cell. Hindwing usually vinaceous cinnamon, the lines faint; inner margin with a light buff spot and similar short lines alternating with chestnut-brown lines. Wings below mostly vinaceous cinnamon. Forewing with dark smoky shading from costa before apex oblique to termen. Hindwing: a black line on discocellular; medial line very fine, faint, to inner margin beyond middle; postmedial line slightly curved, dark olivaceous brown outwardly edged with white, reaching inner margin in a little above anal angle. Female: Forewing ochraceous tawny, the lines slightly darker; antemedial vertical, double; outer lines lunular, wider apart on costa, the subterminal with clusters of white scales at veins. Hindwing rufous or orange buff, only the outer line distinct. Expanse: Male 38 mm; female 35—38 mm. Costa Rica; Colombia; Peru.

A. limosa Schs. (89 k). Male: Forewing light greyish buff, the inner margin suffused with light *limosa*. ochraceous buff; faint traces of a slightly darker lunular line; two fuscous spots on discocellular; postmedial line double, well apart, fine lunular with black points on veins; termen narrowly buffy brown from vein 3 to apex. Hindwing light ochraceous salmon; a fine outer line near inner margin, the latter zinc orange and white. Forewing below avellaneous; costa ochraceous salmon; a subapical fuscous shade. Hindwing below avellaneous, the inner half somewhat whitish; a faint darker medial line; outer line more distinct somewhat punctiform. Expanse: 26 mm. Rio de Janeiro, Brazil.

A. tarasia sp. nov. (89 k). Male: Body vinaceous buff with some ochraceous buff mottling on collar *tarasia*. and tegulae. Forewing light olivaceous drab; antemedial and postmedial lines hair brown, double filled in with drab; costal edge tawny cinnamon; some white mottling below costa and on veins of termen; an interrupted terminal black line. Hindwing avellaneous suffused with vinaceous fawn on termen; inner margin tawny cinnamon crossed by white lines; lines very faint, fuscous. Forewing below avellaneous, the apical third suffused with fuscous; costa tawny; a black line on discocellular. Hindwing below vinaceous buff, the lines hair brown, distinct; a hair brown line on discocellular. Expanse: 21 mm. Santa Catharina, Brazil. Type in STAUDINGER collection (Berlin Museum).

A. symphora sp. nov. (89 k). Male: Antenna black. Head and thorax vinaceous buff. Abdomen light *symphora*. ochraceous salmon. Forewing cinnamon drab; base narrowly and costa clay colour; a double antemedial fuscous line, outbent on costa to median; postmedial line double, fuscous, outcurved on costa and vertical, the outer part lunular; a narrow terminal dark shade from vein 2, bifurcating above vein 4. Hindwing zinc orange with dark terminal shading at anal angle. Wings below ochraceous orange, the apex of forewing broadly buckthorn brown. Expanse: 21 mm. Petropolis, Brazil. Type in U.S. Nat. Museum. This species is of delicate build, the antenna with very long pectinations and the abdomen not reaching beyond middle of inner margin of hindwing, otherwise agreeing with *Anticla*.

6. Genus: **Cheneya** gen. nov.

Male: Palpi short, porrect. Antenna bipectinate, the pectinations long. Forewing: costa arched at apex, excised below apex. Vein 2 from beyond middle of cell; 3 and 4 stalked; 5 from middle of discocellular; 6, 7, 8, 9, 11 stalked; 10 absent. Hindwing: termen rounded slightly prolonged at anal angle; vein 2 from near end of cell; 3 and 4 well stalked; 5 from middle of discocellular; 6 and 7 on long stalk; 8 anastomosing with 7 near base.

Type: *Ch. morrissa* Schs.

Ch. morrissa sp. nov. Male: Body vinaceous fawn, underneath avellaneous. Forewing rather thinly *morrissa*. scaled, vinaceous fawn; faint traces of darker antemedial double, and medial wavy lines; a dark point at lower angle of cell; postmedial line double, lunular; terminal fawn colour shading at sinus. Hindwing thinly scaled pinkish buff; scaling denser on inner margin fawn colour with whitish transverse lines medially and post-medially. Expanse: 20 mm. St. Jean, French Guiana.

Ch. irrufata Dogn. Male: Body and forewing pale honey yellow, the wings thinly scaled. Forewing: *irrufata*. costa cinnamon buff; two tawny olive points on discocellular; a remote whitish outer line well outcurved, below vein 4 incurved to vein 2 then slightly outcurved, defined on inner edge by slightly darker honey yellow.

Hindwing: a tawny olive point on discocellular; a subterminal whitish line, incurved between veins 4 and 2. Wings below paler with markings as above. The termen is evenly rounded. Expanse: Male 22 mm; female 29 mm. Pacho, Quindiu, Colombia. The female is more of a smoke grey. The type specimen bears a label of WARREN saying it belonged to his genus, *Agriochlora*, but it does not agree with his diagnosis.

rovena. **Ch. rovena** *sp. nov.* (89 k). Male: Superficially like some of the species of *Quentalia* but in venation belonging to *Cheneya*. Head and collar pinkish cinnamon; thorax pale pinkish buff. Abdomen cinnamon. Forewing mostly sayal brown irrorated with white hairs, the lines darker; antemedial and medial wavyly outcurved, the former with pale scaling on inner edge; an incurved black line on discocellular; space beyond to postmedial patch cinnamon buff; postmedial outbent suffusing with cinnamon brown patch between veins 4 and 6, below vein 4 wavy; outer line white to vein 4 slightly inbent and followed by cinnamon brown widest at costa, below vein 4 lunular; base between veins 2 and 3, between veins 3 and 4 to beyond postmedial, above patch to costa, and broadly on termen more thickly irrorated with white; veins from postmedial to termen irrorated with light ochraceous buff. Hindwing cinnamon rufous; a black spot on discocellular, and fuscous shade from it to termen; a fuscous outer line distally edged with white between veins 4 and 6 and near inner margin; cilia cinnamon brown tipped with white. Forewing below sayal brown; fine parallel outer lines. Hindwing below cinnamon; a fuscous line with some white hairs on discocellular; the lines as in *Quentalia* fuscous, lunular, connected by a chestnut brown patch near inner margin with white scaling above and below it. Expanse: 25 mm. Oaxaca, Mexico (type); another specimen without locality.

7. Genus: **Tamphana** Schs.

Male: Palpi upturned, reaching frons, hairy well fringed in front, the third joint small, porrect. Abdomen extending beyond hindwing with lateral and anal tufts. Forewing with termen slightly rounded; venation as in *Anticla*. Hindwing with anal angle prolonged; vein 2 from beyond middle of cell; 3 and 4 from lower angle; 5 from middle of discocellular; 6 and 7 stalked; 8 and 7 contiguous near base.

Type: *T. marmorea* Schs.

marmorea. **T. marmorea** Schs. (89 k). Male: Forewing largely fawn colour; consisting of fine striations on a pale drab grey ground; antemedial and medial lines fine black, the former from subcostal to vein 1, the latter from costa to inner margin, the space between them pale drab grey inbent on inner margin to base; a white spot on discocellular; postmedial line slightly outcurved, fine, double, chestnut brown, somewhat lunular; a large apical space on costal margin whitish crossed by an inbent light drab grey fascia from costa to vein 5; a small fuscous spot at tornus; a white streak beyond postmedial between veins 2 and 3. Hindwing fawn colour; some chestnut brown and white mottling on inner margin; anal angle benzo-brown; cilia mottled with white. Wings below vinaceous buff, the termen darker; forewing with a whitish streak from apex; hindwing with lines buffy brown, the medial sinuous downbent near inner margin, the postmedial outcurved; a hair brown patch at anal angle. Expanse: 27 mm. Palmeiras, S. E. Brazil; Amazons; Panama.

lojanara. **T. lojanara** *sp. nov.* Male: Very much like *marmorea*. Forewing: a white spot at base below cell; a fine antemedial whitish outcurved line and a more erect medial line converging towards inner margin, the space between buffy brown; two white points on discocellular; the apical white space more quadrate crossed by a sinuous subterminal buffy brown shade; the white space between veins 3 and 2 cut by a dark line and extending to tornus. Hindwing cinnamon drab; cilia tipped with white. Wings below partly suffused with wood brown; the outer line fawn colour minutely wavy; hindwing with a less distinct medial line and some marginal darker shading. Expanse: 31 mm. Loja, Ecuador.

inferna. **T. inferna** Dogn. Male: Head and body mars brown. Forewing: costal and inner margins and a broad antemedial space Prout's brown; base, disc, and termen subterminally above vein 3 to apex dull ochraceous tawny; a white point at upper angle of cell; postmedial line fuscous, indistinct; a similar sinuous subterminal line edging outwardly the ochraceous tawny shade. Hindwing cinnamon brown. Wings below cinnamon drab. Forewing: a white point on discocellular followed by a fine darker, vertical line; the outer line fine, fuscous, almost vertical, preceded and followed on costa by some light ochraceous buff. Hindwing below suffused with buff to outer line; medial line cinnamon brown; postmedial line benzo-brown; russet tufts of hair on inner margin postmedially. Expanse: 28 mm. French Guiana.

maoma. **T. maoma** Schs. (89 k). Male: Palpi dark brown. Antennae light brown. Head, collar, and thorax lilacine brown; a fuscous dorsal line on collar and thorax. Abdomen dull brown. Forewings brown faintly tinged with lilacine and with a few scattered black scales; an antemedial, inbent, fuscous shade; a white point on discocellular; a fine geminate, lunular, postmedial line, indistinct and scarcely darker than ground colour;

small subterminal semihyaline black spots between veins 4 and 7. Hindwings brown; inner margin white with white cilia; the produced anal angle darker shaded. Wings below bone colour shaded with brown terminally. Forewings: the postmedial lines straighter, brown; the subterminal spots as above. Hindwings: some scattered black points; a black spot on discocellular; two brown outer lines, lunular dentate. Expanse: 30 mm. St. Jean, French Guiana.

T. orion Dogn. Male: Body as in *maoma*. Forewing: basal third cinnamon buff followed by a vertical *orion*. mikado brown stripe edged with verona brown; a white point on discocellular. Wing beyond cinnamon buff shading to pinkish buff on terminal space from vein 5 to inner margin; postmedial line faintly inbent, double, lunular. Hindwing cinnamon, somewhat paler on base and termen; verona brown mottling on inner margin. Wings below pinkish buff; black points on discocellular. Forewing: first postmedial line sayal brown, broad, the second line very fine; a subterminal fuscous spot between veins 5 and 6; cilia sayal brown. Hindwing: first line medial, inbent from vein 3 to inner margin; outer line fine, very faint. Expanse: 30 mm. French Guiana. DOGNIN's co-type is the same as *maoma*. The two species are closely allied.

T. praecipua Schs. (89 k). Male: Head and thorax violaceous brown. Abdomen reddish brown. Fore- *praecipua* wing brown, darkest at base, and shaded with lilacine below cell and vein 4; a buff spot on costa before middle, followed by a dark line, angled at end of cell, inwardly oblique to inner margin at one third from base, and followed by a reddish brown parallel line; a postmedial curved, finely dentate, reddish brown line, followed below vein 7 by a blackish lunular line; some buff on costa before apex, shaded below with reddish brown. Hindwings reddish brown. Underneath pale buff, with fine brown lines; a postmedial and subterminal line on forewings; a medial and a postmedial line on hindwings. Expanse: 26 mm. St. Jean, Maroni River, French Guiana.

2. Subfamily: Zanolinae *subf. nov.*

Vein 8 of forewing straight or concave towards costal margin.

1. Genus: **Apatelodes** Pack.

Palpi well developed, thickly haired, stout, erect and projecting beyond the broad frons, last joint very small, hidden. Antennae pectinate to the tips. Forewing broad triangular, with a sharp, often almost falciform apex before which the costal margin is sometimes excavated, distal margin below it likewise with a low indenture, between 5 and 6 with a more or less distinct angle. Vein 2 behind the centre of the cell, 3 shortly before the lower angle, 4 from the latter, 5 from the centre of the cross-vein, 6 and 7 on a short stalk, 7—10 close together from the same stalk, 11 from the cell. Hindwing broad, outside rounded or slightly angular, as long as or shorter than abdomen; 3 and 4 from the same place or separated, 6 and 7 on a rather long stalk, cross-vein rather oblique. Hind tibiae uncommonly broad, of an oval shape and very densely haired. Larva densely clad with long soft hairs, on the 2nd, 3rd and 10th rings with one long thin dorsal pencil each, between them shorter dorsal pencils.

Type: *A. torrefacta* Abb. & Sm.

A. torrefacta Abb. & Sm. (104 a). Greyish-brown, in the ♂ in the costal half more light silvery or *torrefacta*. violettish-grey, near the base of the inner margin with a large chestnut-brown spot, behind it 4 fine brownish transverse lines, the postmedian line bent around the cell, below it slightly incurved, subterminal line dentate, behind it a small subapical hyaline spot. Hindwing red-brown, at the inner margin whitish with small chestnut-brown spots and a fine light median line. Larva yellow, adult larva mostly with white or grey hair, pencils black, dorsal spots black. It lives on numerous foliage trees, preferably Prunus, willows, ash-trees etc. Widely distributed in the U.S.A. from New York to Texas and Florida. The form from Florida: — **floridana** H. Edw. *floridana* has a redder ground-colour, weaker lines, a distinctly prominent whitish discal spot; under surface fox-coloured.

A. adrastris Drc. (= *diffidens* H.-Edw.) (140 a). light greyish-brown, more or less tinted yellowish *adrastris*. ochreous, lines much like those of *torrefacta*, from the first quarter of the costal margin a dark line extends towards the anal angle; the basal inner-marginal spot broadly parted by vein 1, red-brown with a bronze tint; a whitish discal spot rather distinct. Hindwing somewhat lighter, otherwise of the same tint. Mexico, Guatemala. — **costaricensis** f. n., from Costa-Rica, are greyer, smoother and glossier, lines more regular, not so strongly wavy. *costaricensis*.

inviolata. **A. inviolata** Dogn. (140 a) is somewhat like *adrastris*. Forewing above yellowish-grey, transverse lines hardly darker and rather indistinct; before the centre 2 lines, the extrabasal one twice angled and strewn with black, the exterior one bent, wavy; the postmedian line excurved behind the cell, the undulately dentate subterminal line blackish with more prominent vein-dots and, like *adrastris*, with a deeply dentate antemarginal line between 4 and the apex; above the whitish-scaled cross-vein a light reddish spot; subterminal and marginal areas strewn somewhat darker. Hindwing somewhat more reddish, at the inner margin marked brown with a white oblique streak above the anal angle. Expanse of wings: 44–48 mm. San Antonio, Cali, Colombia.

sublunulata. **A. sublunulata** Schs. (140 a) is very similar to *adrastris*, ground-colour more whitish; basal area defined by a white line extending very obliquely distad from the 1st fifth of the costal margin, returning acute-angled on the median and then almost vertically to the inner margin; the inner-marginal spot is almost entirely absent and only indicated by a brown border of the white line; lines as in *inviolata*; a white subterminal line extends from the costal margin to 6 vertically downwards and is then interrupted by a spot of darker irroration, below it undulately dentate again and widened. Hindwing ochreous with a fine double postmedian line filled with white. Under surface not so red as in *adrastris*, the black, distally white postmedian line of the hindwing is wavy between 5 and the inner margin. Venadio, Sinaloa, Mexico.

brückneri. **A. brückneri** sp. n. (140 a) resembles a pale *sublunulata*, of a soft greyish-brown colour, without any trace of the oblique line from the costal margin to the anal angle; lines as in the preceding species, but all very fine, the two median ones double, somewhat faded and in feebly darker brownish clouds; the two basal inner-marginal spots are situate one above the other and punctiform; the subapical small white hyaline spot is very small, outside pupilled black. Hindwing somewhat lighter, at the inner margin whitish with 3 brown strigiform spots near the anal angle. Under surface very pale and indistinctly marked. Guatemala. Type 1 ♂ in the Berlin Museum.

banepa. **A. banepa** Drc. was not before me. According to the kind information by SCHAUSS it is very near to *heptaloba*; greyer, the dark basal inner-marginal spot very distinct; postmedian line bifurcating below the costal margin and expanded into a triangle with dark spots and a small hyaline spot. South-Eastern Peru, S. Domingo.

heptaloba. **A. heptaloba** Drc. (= *bunca* Dyar) (140 a) is larger than the preceding ones, in marking almost the same, in colour red-brown with a cinnamon pink tint; the basal inner-marginal spots reduced to two narrow streaks one above the other, behind the antemedian line with an obsolete broader wavy shadow which is connected below the cell with the similar postmedian shadow by similar irroration. Subterminal line fine undulately dentate with a blurred spot-like parallel shadow behind it; below the apex a small white subapical spot. Hindwing lighter pinkish-brown with 2 indistinct obsolete nebulous antemedian and postmedian bands being darkened like spots at the inner margin. Mexico. According to the kind information by TAMS the figure in the Biologia is not good, the inner margin of the hindwing in the type shows the usual marking and is not without markings.

sericea. **A. sericea** Schs. (= *erecta* Dogn.) (140 b) has narrower wings than the preceding species, the apex not produced, with a uniform distal margin. Forewing light reddish-brown, marked very much like *heptaloba*, the fine antemedian line rectangularly angled on the median, from there almost vertical to the inner margin, double, filled with lilac white, interior line bordered with dark brown, exterior line distinctly blackish-brown, slightly notched, behind it in the feebly darker inner-marginal shading 2 transverse streaks of lilac white scales. Brazil (Rio de Janeiro, São Paulo).

palma. **A. palma** Drc. (140 b) is much larger than *heptaloba*, with more elongate wings, colour of wings more blackish-brown with a more yellowish tint, marking the same though somewhat less distinct, in the distal inner-marginal half shaded with blackish, with 2 very large velvety black basal inner-marginal spots, the lower one wedge-shaped with the point basad, the upper one more oval. Hindwing with a slight reddish tint, a large black subanal spot, and a short white line below it. Colombia, also from the Songo (Bolivia).

milma. **A. milma** Dyar (140 b) is very much like *heptaloba*, but almost by two thirds smaller, of a duller and lighter colouring, less red, markings very similar though much finer. Hindwing but little lighter. Mexico.

sadisma. **A. sadisma** Dyar (140 b) is still somewhat lighter, similarly coloured and marked as *milma*, the basal 2 inner-marginal spots which are small, strigiform in *heptaloba*, are represented here by dull brownish grey clouding; two small, subapical, white, semitransparent triangular spots, inwardly bordered by blackish-brown.

schreiteri. Mexico, Misantla. — **schreiteri** Schs. (140 b) of which there are several specimens before me from Argentina is hardly a different species, although the far remote patiae are very remarkable; still somewhat smaller with somewhat finer markings; I can find no other difference. The origin of 3 and 4 from the same place, as it is stated for *schreiteri*, or separated, varies in both forms and is no constant mark of distinction.

velutina. **A. velutina** Schs. (140 b). Head and tegulae violettish grey, mesothorax dark brown, the brown abdomen scaled grey on the posterior edges of the segments. Forewing basally light brown, bordered by a dark line which is strongest at the costal margin; it extends obliquely to below 2, whence it turns towards the inner

margin, the basal inner-marginal spot before it appears as a dark brown shadow; median area velvety grey with a light streak at the cell-end and outside bordered by the dark undulate postmedian line; at the distal margin reddish mixture; a dark subapical velvety brown spot inside bordering on 2 small transparent white spots. Hindwing reddish brown, anally much darker, above it with the beginning of a transverse line. Described from 1 ♀ with an expanse of 38 mm, from São Paulo.

A. zikani *sp. n.* (140 b) is very closely allied to *velutina*, somewhat larger, greyer, but otherwise with *zikani*. the same scheme of markings; the basal inner-marginal spot is larger, more distinctly defined blackish-brown; the oblique stripe extending from the first quarter of the costal margin towards the anal angle is particularly stronger in the upper half; at the cell-end there is a small heap of more whitish scales; at the margin between 3 and 7 some copper-bronze shading, being broadest on 5. Hindwing somewhat redder than forewing with a feebly darker median band which is almost rectangularly angled on 5 and outside bordered by a fine light line. Passa Quatro, Minas, Southern Brazil; type a ♂ in coll. J. ZIKAN.

A. thinaha *sp. n.* (140 c) is near to *brückneri*; more coarsely scaled, of a darker blackish-brown ground- *thinaha*. colour, the oblique costal-marginal stripe is merely a fine nebulous line, instead of the basal inner-marginal spot there is only a very hazy, small, hardly darker cloud; the fine undulately dentate exterior line is much straighter and not indented behind the cell as in its allies; the exterior median line forms a broad, faded, dark median shadow; subapically only a small white triangular spot on both sides bordered with blackish-brown. Hindwing almost darker greyish-brown than forewing, at the inner margin with a distinct white postmedian oblique streak, above and below bordered by blackish-brown. Passo Quatro, Minas. Type 1 ♂ in coll. ZIKAN.

A. lacetania *Drc.* (= *hiantha* Dyar) (140 c). Light grey, feebly strewn with brownish; anterior transverse *lacetania*. line double, indistinct, at the inner margin it forms 2 small lunular spots one above the other, inside bordered with black; the costal-marginal oblique streak is outside shaded with brownish grey, it is crossed on 2 by the slightly curved postmedian line; the exterior transverse line is undulately dentate as in the preceding species; a short white subapical undulate line to which an isolated round white spot is attached between 6 and 7, inwardly bordered by long, strong black wedge-streaks; marginal area feebly darkened. Hindwing slightly redder with a curved whitish median line which turns whiter at the inner margin, above and below bordered with blackish-brown here. Mexico, Zacualpan; somewhat smaller, browner and darker from Mexico City, apparently very variable.

A. parvula *Schs.* (140 c) is smaller than the preceding species; body brownish-grey; base of abdomen *parvula*. and 2 transverse bands on the thorax darker; forewing grey, strewn with brown, the basal inner-marginal spot very large, dark brown, not reaching the base, outside feebly bordered light; the oblique band from the costal margin brownish, not reaching the anal angle; the veins situate outside the oblique band are all lighter than the ground; at the cell-end a light patch; exterior transverse line distinct whitish, indented behind the cell; 2 semitransparent small subapical spots inside bordered with blackish-brown. Hindwing brown, inner margin greyer and darker, with a whitish postmedian line. Expanse of wings: 28 mm. Castro, Parana; Paraguay.

A. amaryllis *Dyar* (140 c) is a larger beautiful species, olive grey, with distinct light veins, of the two *amaryllis*. basal inner-marginal spots the upper one is extended almost to the base as a long black wedge-streak, the lower one only half as long and more indistinct; anterior transverse line whitish, in the costal half as the interior border of the darker oblique band; of the two distal transverse lines the interior one is fine olive brown, the exterior one white, forked to the costal margin on 6, enclosing a black triangle parted by white between. Hindwing lighter with a slightly darker median band, distally bordered by a white line which is angled submedianly and on 5. Mexico.

A. pudefacta *Dyar* (= *uvada* Barnes) (140 c) is light grey, with black basal inner-marginal spots, the *pudefacta*. lower one larger, outside bordered with whitish, then again dark; the white oblique costal-marginal streak borders on a brownish oblique band which is widened at the inner margin towards the anal angle; at the cell-end a whitish patch; the interior line of the two distal transverse lines is quite indistinct and hardly darker, the exterior one white and shaped as in *amaryllis*. Hindwing likewise as in *amaryllis*. — **doramia** *Dyar* is only a *doramia*. more brownish form from the same habitats, with all kinds of transitions. Arizona to Mexico.

A. jessica *Dyar* (140 c) is extraordinarily similar to *pudefacta*, but from the same patria without any *jessica*. transitions, for which reason it is regarded a distinct species. Altogether smaller, greyer, the basal inner-marginal spot small, of a dull brownish grey, obsolete, not distinctly bipartite, the interior one of the two distal lines finer and more distinct than in *pudefacta*; the whitish median line on the hindwing uniformly bent, not angular. Mexico (Zacualpan). — **maudamia** *Dyar* is a northern form from Sinaloa, approximating more *pudefacta* by *maudamia*. the more curved line on the hindwing and the distinct blackish-brown basal inner-marginal spot on the forewing; the white distal line is less distinct and the blackish-brown subapical spots are outside not bordered by 2 separate white spots, but by a white short undulate line. — **floramia** *Dyar*, from Guatemala, likewise approxi- *floramia*. mates *pudefacta*, but the oblique white line from the costal margin cuts here the dark distal line and is prolonged to the white subterminal line near the anal angle; on the hindwing the white line is angular as in *pudefacta*, far proximad remote from the margin and proximad to it there is a parallel dark line.

lescambia.

A. lescambia Dyar (140 c) resembles *jessica*, but it is much smaller, with narrower wings, the distal margin not so convex. Light grey, base of abdomen with a dark belt. Forewing basally lighter, the very broad white oblique costal-marginal line extends along 2 as far as the white subterminal line, where it forms a very pointed tooth, returning on the submedian fold to the oblique white antemedian line, on the inside of which the indistinctly bipartite basal oblique inner-marginal spot is situate; behind the white distal line which is inside finely bordered with dark there is another white subterminal line parallel to the margin, touching the preceding line above the anal angle and on 5; in the fork there are two small black triangular spots. Hindwing somewhat more brownish with a eurved whitish median line. Mexico (Tehuacan).

paraguayana.

A. paraguayana Schs. (140 g). Forewing pale yellowish loam-coloured, in the median area dusted with olive grey, the basal inner-marginal spot a long narrow black spot obliquely distad above, the feeble antemedian line angular behind the end of the spot, the postmedian line rectangular on 5, below it distinctly black, towards the margin somewhat concave; the subapical dark spot inside indistinct; outside straightly bordered with white, the apex behind it feebly darkened. Hindwing olive-grey, in the costal half with a slight chestnut-red reflection, with a strong whitish postmedian line above which there is a small black spot at the inner margin. Paraguay.

batima

A. batima Dyar, described after a ♀, is ashy grey, forewing clouded with olive brown, the basal inner-marginal spot brown, parted lighter, behind it the brown, eurved, interrupted interior line extending on the median vein and 2 towards the anal angle; the brown median line is inwardly shaded; at the cross-vein a pale spot; the interior one of the two distal lines is brown, shaded, behind the cell far excurved and submedianly somewhat less, the exterior line is finer, blackish, behind the cell likewise excurved and submedianly somewhat less, the exterior line is finer, blackish, behind the cell likewise excurved; subapically two white punctiform spots, inside bordered with brown, below them brown shading at the distal margin. Hindwing suffused with dull reddish with a white line and before it a feeble reddish line, both intensified at the inner margin. Expanse of wings: 44 mm. Iguala, Guerrero, Mexico.

gladys.

A. gladys Dyar (140 d) is very closely allied to *batima*, but the forewing is dark brown with a reddish cinnamon tint, with fine lines, the two distal ones excurved behind the cell and very feebly waved between the veins; the oblique line from the costal margin extends along 2, whence it turns, distally shaded, between the two distal lines vertically to the inner margin, with dull basal inner-marginal spots; a small round white subapical spot. Hindwing hardly more reddish with a feeble median line angular between 5 and 6, intensified at the inner margin. Mexico, Zacualpan.

verena.

A. verena Drc. (= *horina* Schs.) (140 d) is larger than the preceding species, with somewhat more elongate wings, more blackish grey, similarly marked though well discernible by the double postmedian line the parts of which are hardly more than 1 mm distant from each other, feebly excurved behind the cell, inwardly concave between 2 and 4, slightly excurved again below 2; two basal inner-marginal deep velvety brownish black spot one above the other, the oblique costal-marginal line rather indistinct. Hindwing marked as in the allies. Mexico.

turrialba.

A. turrialba Schs. (140 d) is very similar to *verena*; palpi velvety blackish brown, head and thorax brownish mixed with grey, on the hindhead blackish; abdomen somewhat lighter. Forewing grey, transverse lines and vein 2 finely black; 3 antemedian lines close together, the innermost oblique from the costal margin to 2, then undulate to the inner margin, before it 2 small black spots above and below the submedian fold, the median line being faint and interrupted, the exterior line feebly bent, distinct; 2 postmedian distantly separated lines, obliquely from the costal margin, feebly bent below 4, between them a fine indistinct dark double shadow; between 6 and 7 a small white subterminal spot. Hindwing basally dark grey, behind it a broader still darker median shadow, angular on 6 and submedianly; distal half somewhat lighter silky-glossy grey; at the anal angle white-sealed with a blackish inner-marginal shadow above it. Volcano of Turrialba (Costa Rica), from an altitude of 5800 ft.

firmiana.

A. firmiana Stoll (140 d) introduces a group of externally very similar large species with yellowish-grey forewings with darker transverse lines. *firmiana* is characterized by the very feebly developed subapical triangular dark costal-marginal spot which may be almost absent; the basal inner-marginal spot is blackish-brown, large, not parted and above rounded; the first olive grey, somewhat feebler transverse line forms a very pointed angle distad above the submedian fold, the second (antemedian) line forms on 2 a rectangular angle or a more rounded curve; the postmedian line extends from close behind the centre of the costal margin to close before the anal angle in a feeble distally convex curve, the median area between the two latter often being strewn somewhat olive grey; the subterminal line arises about 5 mm farther outside, forming a larger curve and extending directly into the anal angle; the subapical triangle is but very feebly darkened, outside bordered by a straight whitish streak behind which the upper marginal half is darkened olive grey. Hindwing blackish-brown with a slight copper reflection and a light, on 5 angular postmedian line; in the lower inner-marginal half a dark brown spot above and below bordered with light; a feeble darker antemedian band is mostly very indistinct. Beneath on the forewing with a short discal streak, a rather straight line behind it and a bronze brown subapical marginal triangle which is proximad straightly defined by whitish; hindwing with a bronze brown triangle below the cell from the base to the subterminal line which is concave here towards the margin. Guiana, Colombia, Brazil to Sa. Catharina. In the Berlin Museum there is a very small specimen of an expanse of only 36 mm, from Colombia.

A. diana Dogn. (140 e) has broader wings and is darker, the first transverse line is only somewhat angular *diana*. on the median vein, the 2nd antemedian line is almost quite straight, the postmedian line as in *firmiana*, but it ends farther before the anal angle, the subterminal line is less bent, dying away more and more towards the costal margin; a large subapical blackish-brown spot, inwardly faded, distally somewhat angular and bordered by a purer white. Hindwing slightly darker brown, without distinct lines. Beneath on the forewing the red-brown apex is traversed by 2 white subapical streaks; on the hindwing the postmedian and subterminal lines form an irregular V, being broad at the costal margin and united at the inner margin; the red-brown wedge is smaller. Colombia.

A. mehida Drc. I do not know, according to the kind information by TAMS the type was not to be found; *mehida*. it must be very similar to *diana*, but the red-brown hindwing shows above an undulated light greyish-brown band from the centre of the costal margin to the centre of the inner margin. Beneath the hindwing is dark red-brown, with a light submarginal line, and the abdomen beneath is dark brown. South-Eastern Peru.

A. dianita Dogn. (140 e) is above yellowish greyish-brown on the forewing, the basal inner-marginal spot *dianita*. is bipartite, the lower half a long wedge extending almost to the base; the first antemedian line in its upper portion somewhat wavy, inside bordered by a lighter shade; the 2nd antemedian line and the postmedian line are almost straight, between them often a discal dot, the subterminal line angular between 6 and 7, the subapical triangular spot inside sharply defined, outside adjacent to its white border mostly yet a punctiform spot between 6 and 7. Hindwing greyish-brown, the light postmedian line on 5 with a distinct angle. Beneath on the hindwing the postmedian line is situate farther towards the margin, inside of it the hindwing is blackish-brown, distally lighter. Bolivia (Songo).

A. princeps Dogn. (140 d), described after a female, is very similar, browner, the basal inner-marginal *princeps*. spots smaller, more distinctly separated, outside bordered by an almost pure white colour; the 2nd antemedian line is more bent, the postmedian line S-shaped, between both a distinct cell-end dot or streak. Hindwing hardly darker than forewing, the light postmedian line less bent, not angular. Hindwing beneath brown, with a darker median band outside bordered with light, inside with dark. Colombia. The figured browner ♂ from the Coll. W. HOPP-Charlottenburg from Chachatoy, Colombia, undoubtedly belongs to it.

A. ilia Dogn. (140 e) is likewise very similar to *firmiana* from which it chiefly differs in the large *ilia*. subapical blackish-brown triangular spot of the forewing, which is surrounded by the white fork of the straight subterminal line; in *firmiana* the median area, in *ilia* the space between the postmedian and subterminal lines is darkened. Hindwing: the whitish postmedian line is quite straight between the costal margin and the submedian fold, or it shows a slight angle on 6. The larger ♀ is mostly lighter yellowish-grey. Hindwing beneath also similar as in *firmiana* in which, however, the median band forms a very pointed distal angle on 5, whilst here it extends as above, rather concave towards the margin. Colombia, Brazil.

A. imparata Dogn. (140 f) looks like a small specimen of *ilia*; ground-colour much lighter; the basal *imparata*. inner-marginal spot and the subapical triangular spot are much smaller and paler, the former more strigiform. On the feebly reddish hindwing the light, somewhat bent transverse line is much nearer to the margin. Described from Paraguay.

A. quadrata Jones (140 g) is somewhat like *imparata*; forewing very light greyish-yellow, the basal inner- *quadrata*. marginal spot very large, deep velvety brownish-black; the two antemedian lines feeble, the postmedian line more intense; the subapical triangular spot is bipartite, the upper portion smaller. Hindwing reddish-brown, the marking from beneath feebly showing through, this marking being very characteristic and forming a large chestnut-brown trapezoid spot with a tail-like appendage between 5 and 6 almost to the margin, another one to the white-dusted inner margin near the anal angle, and a very short one to the costal margin behind the centre; the spot itself begins pointed at the base. Brazil; before me from S. Paulo.

A. pandara Drc. (140 e) the female type of which is before me from Panama (Chiriqui) c coll. STGR. is *pandara*. most similar to *ilia* which it resembles almost entirely in the marking; but the colour is quite different, on the forewing reddish light brown, on the hindwing distinctly red-brown; on the forewing the first antemedian line is continued analwards as an oblique stripe along vein 2, as it is the case e. g. in the *adrastria*-group. Beneath likewise marked as *ilia*, but the colour is a warm red-brown. Panama to South Brazil.

A. pandarioides Schs. (140 e) is very similar, on an average somewhat smaller, more pinkish-brown. *pandarioides*. the postmedian line almost quite straight. Hindwing beneath the same, but much more clearly and distinctly marked, especially the almost pinkish-white postmedian line. Guiana, Amazons to Brazil.

A. pithala Dogn. (140 f) resembles *pandarioides* in the colour, but the wings are more stretched with *pithala*. an obliquer rounded distal margin; the basal inner-marginal spot is very large, the subapical triangular spot, however, altogether absent; all the lines only feebly marked, slightly bent, the subterminal line which is outside

finely bordered with light not angular on 6 but rounded. Beneath the dark wedge below the cell of the hindwing is indistinct. Bolivia.

lapitha. **A. lapitha** Drc. (140 f) is very much like *pithala*, but with a less red tint, and purple grey dusting towards the anal angle and margin; the fine light subterminal line is inwards hardly bordered with dark, being situate much nearer to the margin, much straighter and forming a very short fork between 6 and 7, in the angle of which there is a tiny dark dot; also on the hindwing the subterminal line is much nearer to the margin. Mexico to Colombia.

kotzschi. **A. kotzschi** n. sp. (140 f) is presumably the Brazilian representative of *lapitha*. Wings still more stretched, with an obliquer distal margin forming a slight angle on 5. The colouring is more loamy, not so pink; the marking otherwise very similar excepting the whitish subterminal line which is much obliquer and extends straight into the apex and does not bifurcate below the costal margin; behind it the marginal area is intensely darkened blackish-brown as far as into the apex, in *lapitha* the apex itself remains light. On the hindwing the fine light postmedian line is much more removed into the centre of the wing. Type: 1 ♂ from Sa. Catharina e coll. WERNICKE-Dresden.

cirna. **A. cirna** Drc. (140 f) shows resemblances to the 3 last species; ground-colour light ash-grey, at the costal margin much lighter, at the inner margin tinted ochreous, the basal inner-marginal spot large, pointed towards the base, outside rounded, here finely bordered with white, with 2 fine red-brown short lines behind it, the exterior line finely crenulate; the two transverse lines very fine and feeble, the exterior line angular on 5; at the cell-end a very fine dark dot, marginal area somewhat darkened. Hindwing monotonously ash-grey, at the lighter inner margin with 2 fine brownish-black angular streaks near the anal angle, the lower one being outside bordered with a purer white. Mexico.

cerrita. **A. cerrita** sp. n. (140 f) cannot be compared with any other species. Basal area light cinnamon-brownish, central area light chocolate, marginal area lighter and more yellowish than the basal area; from the first quarter of the costal margin a very thick oblique stripe extends to vein 2 and along it to the exterior transverse line; instead of the basal inner-marginal spot a very large irregularly roundish spot strewn with black and somewhat more distinctly bordered with black; before the double, finely dentate exterior transverse line, which begins close before the apex, 2 black oblique costal-marginal streaks, behind it between 6 and 7 two small hyaline spots; marginal area in the upper half dusted somewhat grey. Hindwing unicoloured light red-brown, at the inner margin two dark spots interrupted by light. Tegulae of the colour of the basal area, before their black margin with a black parallel line. Described after 2 ♂♂, type from Passa Quatro, Minas, Brazil, in the Coll. ZIKÁN, eo-type in the Senckenberg Museum at Frankfurt on the Main.

singularis. **A. singularis** Btlr. (140 g) is likewise a very peculiar species, originally described as a Geometrid (*Endropia*). Light brownish, in the marginal area more whitish, at the costal margin at about equal distances 4 narrow, small, black longitudinal spots; the basal inner-marginal spot as in *paraguayana* very long and thin, outside accompanied by a fine parallel line; the antemedian line is very irregular, forming a very wide bow, below the cell behind it a somewhat thicker spot; in the cell and behind it along vein 5 a dark longitudinal wedge to the margin; postmedian line angular on 5, above it indistinct, below it towards the margin concave, fine, a little dotted on the veins; the outermost costal-marginal spot is situate in a white arcuate line which belongs to the otherwise hardly visible subterminal line. Hindwing somewhat darker reddish-brown with a broad lighter median band on both sides bordered with a darker colour. Not mentioned where it was found.

datanoides. **A. datanoides** n. sp. (140 g) is a small species looking exactly like a small *Datana*; cinnamon red-brown with 3 darker transverse lines, the first on the median vein with a rounded angle, the second being postmedian, almost straight, thicker than the others, the third about 2 mm behind it somewhat concave towards the margin; fringe somewhat darker brown. Hindwing hardly lighter, without lines with darker fringe and the usual small inner-marginal spots. According to 2 males from Mexico (exact habitat not stated); type in the Berlin Museum.

castanea. **A. castanea** Jones I do not know, it may belong near to the preceding species. Body chestnut-brown, thorax suffused with purple, the basal abdominal segments with purple brown rings. Forewing chestnut with distinct dark feebly excurved antemedian and postmedian transverse lines; above 6 a small white subapical spot, and at the cross-vein a small dark dot. Hindwing chestnut, towards the base ochreous. Beneath on the chestnut forewing the basal half, excepting the costal margin, dusted with grey, the white subapical spot larger than above. Expanse of wings: 40 mm. Castro. Parana.

erubescens. **A. erubescens** sp. n. (141 a) is quite isolated. Forewing light reddish-yellow, strewn with red-brown, the most densely in the basal inner-marginal spot, in the median area as far as the subterminal line and before the margin, the space behind the subterminal line remaining purest yellowish; a curved antemedian line is very indistinctly traceable, the somewhat more distinct reddish-brown postmedian line extends from close behind the centre of the costal margin to shortly before the anal angle and it is slightly undulated outwards between the veins; the subterminal line distinctly borders on the dark median area, being obtusely angled on 5 from where it runs in a straight line to the anal angle. Hindwing paler with a slightly darker median and

marginal band, both being darkest at the inner margin. Beneath the hindwing is somewhat darker cinnamon brownish and besides a fine dark median line as on the forewing with a whitish submarginal line being inside bordered with a darker colour. Type a ♀ from Brazil in the Berlin Museum.

A. paulista Jones is not before me, but it may belong to this group. Palpi red-brown; head and thorax grey, abdomen yellowish-brown. Forewing grey, strewn with yellowish brown, with a light brown undulate antemedian band and a broader similar postmedian band the outer border of which is darker and undulately dentate; marginal area dusted with brown, fringe brown, at the cell-end a whitish spot. Hindwing yellowish-brown with indistinct median and postmedian lines and grey fringe. Beneath the forewing is yellowish-brown with faded brown median and postmedian lines, behind the latter a brown shadow. Hindwing similar, the postmedian line angular on 5; marginal area suffused with grey, a white discal spot. ♀ similar, darker. Expanse of wings: ♂ 47, ♀ 57 mm. South Eastern Brazil (S. Paulo).

A. striata Drc. (140 f) is quite a different species. Body and forewing fawn, forewing with 6 angular lines near the apex; at the apex a white spot and near the base of the inner margin a small black spot; fringe fawn. Hindwing fawn with lighter veins. Under surface light fawn, hindwing in the centre with 2 undulate light lines and at the apex with a large brown spot. Peru, La Union, Rio Huacamayo, from an altitude of 2000 m.

A. corema Schs. (140 g) is light reddish-brown with undulate greyish-white antemedian and postmedian transverse lines, between them a fine black discal dot; at the costal margin between the lines with 4 small whitish diffuse spots, the lower half of the median area dusted with greyish-white; between 4 and 6 two small submarginal hyaline spots, below them a rather straight subterminal line. Hindwing monotonously reddish brown. South-Eastern Brazil (S. Paulo), described after a ♀.

A. paratima Schs. (140 g) is very light yellowish grey, with hardly any transverse lines, only their beginnings at the costal and inner margins being indicated by small blackish-brown spots, in the disc a small central dot, subapically with the white subterminal fork in which there are two small black triangular spots. Hindwing somewhat darker and more reddish with a feeble whitish submarginal line on both sides shaded darker. Costa Rica to Colombia (before me from Mocoa c coll. Hopp). — **lilacina** Jones (140 g) is a darker Brazilian form; forewing tan-coloured yellow, strewn with olive brown, the basal inner-marginal spot much larger, the transverse lines more distinct, especially the curved postmedian line, and behind it a sharply crenulate fine dark subterminal line. Hindwing chestnut with a distinct whitish subterminal line. South-Eastern Brazil; Amazons (Tonantins).

A. xanthapex sp. n. (141 a) is evidently very closely allied to the preceding species, but easily discernible by the golden yellow upper marginal half, below it the margin is smoked greyish-brown. Colour of the wings as in *paratima*, the basal inner-marginal spot much larger, extending to the base; the very fine transverse lines are blackish-brown, the antemedian line angular on the median vein, the postmedian line begins with a larger costal-marginal spot, bends round the fine discal dot and runs then finely crenulate towards the margin feebly concave to the inner margin. Subterminal line wavy, with fine black vein-streaks, terminating below the costal margin with a large white spot which sends a branch to the apex; in this fork a large blackish-brown triangular spot. Type: 1 ♂ from Passa Quatro (Minas) in the Coll. ZIKÁN. — **garleppi** f. n. (141 a) I range here for the present, it corresponds to the form *lilacina* of the preceding species. Forewing on the golden yellow ground densely strewn with brown, only the apex remains purely golden yellow though less extensively than in *xanthapex*; linear marking very indistinct in the densely strewn ground, the subapical black triangular spot is parted in two by a broad white vein. Hindwing chestnut with a fine white submarginal line. Type: 1 ♂ from Huayabamba (Peru) in the Berlin Museum (Garlepp leg.)

A. hierax Dogn. (141 a). Forewing grey, behind the base and at the costal margin hued with reddish-brown, the basal inner-marginal spot large; transverse lines indistinct, only their beginnings at the costal and inner margins are marked red-brown; 3 white subapical spots inside bordered with red-brown; subterminal line hardly more distinct than the other lines. Hindwing light red-brown, at the margin hued with grey, with a feeble lighter median line. Described after a ♂ from Joinville (Brazil).

A. anna Schs. (141 a). Forewing violettish-grey, suffused with reddish-brown; anterior transverse line feeble, somewhat dentate, rising from a small darker costal-marginal spot, the posterior line somewhat more distinct, often darkened like a band, slightly angular on 5, below it concave towards the margin; at the cell-end a black dot; 2 large subapical hyaline spots inside bordered with dark, below them a third though not hyaline, whitish patch; marginal area subapically darkened. Hindwing more reddish-brown. Guiana; Colombia.

A. martia Cr. (♀ = *bombycina* Fldr.) (140 h). Like the following *albipunctata* the sexes of which undoubtedly belong together, CRAMERS and FELDERS species also belong together. Forewing of ♂ purple grey, in the basal area, a median band and at the margin especially apically chestnut-red, between them wavy transverse lines and subapically a small white hyaline spot. Hindwing somewhat lighter red-brown. The ♀ — a specimen exactly fitting the ♀ type of *bombycina* is before me — is almost quite the same as *albipunctata*-♀,

but the colour is deeper purple brown, the transverse bands and lines have a straighter course. Guiana; Amazons (Pebas). The figure denoted as ♂ of *bombycina* most positively does not belong to it and looks more like *gaveta* Dogn.

albipunctata. **A. albipunctata** Drc. (140 h) is hardly to be separated specifically from *martia* and probably its northern representative; on the whole larger, lighter, otherwise very similarly marked, the transverse lines more curved and more notched, more distinctly greyish-white, the median band in the ♂ broader and more sharply defined. Mexico.

concerpta. **A. concerpta** sp. n. (140 h) is closely allied to the two preceding species, but much larger, more slender and more extensively chestnut-red or better deep Pompeian red, so that torn greyish-white colouring only appears yet at the apex and subterminally, beside the two strongly and irregularly notched transverse lines and the small discal spot; the marginal area below the apex is also Pompeian red. Hindwing somewhat lighter reddish-brown, marked as in *albipunctata*. Type 1 ♂ from Sa. Catharina in the Berlin Museum. — **fucosa** f. n. (141 a) I reckon to be a form of it; here the last greyish-white colour has disappeared altogether, only instead of the transverse lines there are single light scales, and subterminally below the hyaline spots there is a feeble brightening; all the rest is of a deep brownish red, the hindwing as in the typical form. Type: 1 ♂ from Passa Quatro (Minas) in the Coll. ZIKÁN.

ardeola. **A. ardeola** Drc. (140 h). The figure in the Biologia has been made according to a ♀ and exactly corresponds with ours according to a ♀ from Leopoldina (Esp. Santo) from the Berlin Museum. Forewing grey, basal area and a broad median band deep purple brown, the basal area outside dentately bordered with grey, with a purple brown dentate line behind it; in the median band at the cell-end a narrow grey streak; subterminal line fine, crenulate, double, the inner portion on the veins inwardly projecting with small pointed dents, the exterior portion broader, forming distally faded purple brown bows, bordering above 6 on a large hyaline spot which forms the beginning of a submarginal line extending to almost below 3. Hindwing Pompeian red, at the anal angle greyish-white. SCHAUUS ranges here as ♂ his — **vitrea**, described from Costa Rica: thorax above dark violettish-brown, abdomen red-brown; forewing dark brown, below the cell and 4 blackish-grey, otherwise dusted with reddish; instead of the antemedian line scanty whitish scales, below 5 a fine crenulate lilac grey subterminal line, behind it lilac scales; between 6 and 7 a large hyaline spot, between 7 and 8 a smaller one; distal margin above 6 and below 5 somewhat incurved. Hindwing dark reddish-brown, at the anal angle scaled whitish and spotted darker brown. Expanse of wings: 34 mm. I should much rather consider — **mediana** Schs. (140 h), from Paranà, to be the ♂ belonging to *ardeola* the colouring and marking of which fully corresponds with its ♀ type; our figure originates from a Brazilian specimen. *ardeola* was originally described from Panama and the Amazons.

nina. **A. nina** Cr. (141 b) is a small light grey species with a slight reddish tint, the reddish-brown basal area shaped as in *ardeola*; instead of the median band only 2 chestnut-red spots at the costal and inner margin; subterminal line likewise as in *ardeola*, extending almost straight to close before the anal angle; between it and the hyaline spot a red triangular spot at the costal margin; submarginal line as in *ardeola*. Hindwing lighter red-brown, analwards whitish-grey. Guiana to Brazil.

moresca. **A. moresca** Schs. (141 b) is extraordinarily similar, though larger and much darker on the whole; the grey colouring is less reddish, the red-brown colour deep purple brown; course of subterminal line not so straight but rather somewhat concave towards the margin. Hardly to be separated specifically from *nina* and probably its westernmore representative in Peru and Colombia.

lepida. **A. lepida** Schs. (141 b) also belongs yet to this group. Forewing of a soft light grey, the basal area not darker, outside bordered by a fine notched line, adjacent to the latter at the costal and inner margins one dark red brown spot each, the median area remaining light, at the cell-end a fine black streak; at the costal margin a large postmedian red-brown trapezoid spot; postmedian line very indistinct, with fine vein-dots, an irregular subterminal line is somewhat better marked, between 6 and 7 a hyaline spot; fringe dark brown. Hindwing as in the preceding species though less red. Described from Dutch Guiana.

tropea. **A. tropea** Schs. (141 b), described as *Thelosia*, is now ranged here by SCHAUUS; it looks exactly like a small *Olceclostera*. Forewing grey, in places dusted with brownish and strewn with blackish-brown, with a notched brownish, finely darker edged antemedian band, a light grey cell-end streak, and a brown postmedian band; the interior very dark border-line is not notched, only feebly bent, the exterior line regularly notched, on the outside of it below the costal margin a small white spot and faint traces of a short dark submarginal line in the upper half of the distal margin. Hindwing very light, brownish-white, fringe somewhat darker. Castro (Paranà).

pervicax. **A. pervicax** Dogn. (141 b) was described as *Zanola*; forewing light yellowish red-brown with 3 almost straight transverse lines, the antemedian and postmedian ones on the averted sides bordered with whitish, the

median one at the cell-end distally angular, before the margin a cucullate line as in *Zanola* and *Colabata*. Hindwing hardly lighter with a distinct brown sinuous postmedian line. ♀ of a somewhat lighter and greenish shade. Colombia.

A. infesta Dogn. (141 b) belongs to the same group. Shape of wings narrower; forewing yellowish red-brown with 3 parallel darker brown, almost straight transverse lines, at the cell-end with a fine dark dot; subterminal line inside with traces of a fine parallel double line and outside indistinctly bordered with red-brown, at the costal margin darker in the shape of a spot, likewise with a cucullate line before the margin. Hindwing hardly lighter with a fine discal dot and 2 postmedian lines obtuse-angularly bent between 4 and 5. Colombia (Mt. Tolima, 3200 m), described after a ♀.

A. narda Schs. (141 b) looks different and was described as *Colabata*. Variable. Forewing whitish, more or less densely dusted with ochreous yellow, in some specimens the median area remains whitish with a feebly flesh-coloured tint, traversed by 3 oblique slightly bent parallel lines, the antemedian line inwardly bordered with whitish, the median line plainly red-brown, passing behind the black discal dot, the postmedian line far outside, looking like a white-filled double line, outwards fadedly bordered with brown; before the margin a feebly notched cucullate line. Hindwing white, with or without a rather distinctly defined brownish marginal band, sometimes besides with a fine feeble line before it and a blackish discal dot. Brazil (Castro, Paraná; Minas).

A. gaveta Dogn. (141 c) is only known to me from the figure; it was described as *Datana*, but it probably belongs to this place here and may be a smaller darker form of *narda*. Ground-colour darker cinnamon-reddish, with a broad red-brown antemedian band; the median area with the black discal dot remains lighter; the median line appears here also double like the exterior line, though not filled with white as the latter, but darkened; marginal area behind the cucullate line lighter. Hindwing light reddish brown. Ecuador, Loja.

A. satellitia Wkr. (141 c) is very different from all the species; forewing light violettish-grey, strewn with brownish, at the costal margin, basally, and in an oblique patch from the centre of the lower cell-end behind the centre of the inner margin of a purer bluish grey. Transverse lines fine and indistinct, subterminal line with fine vein-dots; at the cell-end a bean-shaped purple brown spot in a whitish ring; subterminally a purple brown spot comes down from the costal margin, inwardly faded, outwardly bordered by 3 white triangular hyaline spots, outside bordered with reddish-yellow. Hindwing and abdomen reddish-brown. Widely distributed in Brazil.

A. ennomoides Wkr. (141 c) initiates quite a different other group. Forewing light yellow with 2 narrow, very feeble reddish-brown antemedian and postmedian transverse bands, the anterior one being almost straight, the posterior one distally angular behind the cell and submedianly, between them a fine black discal dot; traces of an undulate-dentate subterminal line with vein-dots; marginal area darkened reddish-brown, subapically between 4 and 6 with two small white hyaline dots; fringe dark brown crossed by light. Hindwing lighter, at the margin brownish, with 2 brown straight parallel lines. Guiana to Brazil (Pará).

A. tuisa Schs. (141 c) is very similar to *ennomoides*, strewn with somewhat more brownish, the anterior transverse band consists of but one line which only bifurcates below the costal margin; the discal dot is distinctly white-ringed; postmedian line as in *ennomoides*, between the small hyaline spots spotted red-brown, also at the costal margin subapically a red-brown strigiform spot. Hindwing with a distinct median spot and a curved line close behind it and a less curved line farther outside. Costa Rica.

A. pertuisa Dogn. is similar to the preceding ones, somewhat more intensely marked. Forewing light ochreous yellowish, especially basad strewn darker, the antemedian transverse band blackish, very irregular, behind it 2 very irregular brownish lines with a brownish shadow between; the blackish postmedian line is notched and, behind the cell, strongly angled; margin strewn with brown. Hindwing as in *tuisa*. Venezuela.

A. taperinha Dogn. (141 c) is marked the same, the ground-colour somewhat more whitish, the marking blackish, with cloud-like spots, especially the antemedian band; discal spot larger, oval; the two postmedian lines are distant from each other, both undulate-dentate; of the two lines on the hindwing the interior one is feeble, brownish, the exterior one stronger and blackish. Amazons; Novo Friburgo.

A. olaus Schs. (141 d) almost resembles a *Thelosia*; forewing on the ochreous ground densely strewn with purple brown and lilac white, with 4 brown transverse lines; the two antemedian ones parallel, little curved, the 2nd thicker than the first; median line thickest, feebly S-curved and at the cell-end interrupted by the lilac-white cellular spot; postmedian line fine, rectangularly broken on 6, below it feebly undulate-dentate; behind it another whitish submarginal patch from the apex slightly towards the margin concave to the anal angle. Hindwing ochreous with 2 faint darker lines. Argentina.

A. signata Drc. was not before me, but according to the insignificant description it evidently belongs near *olaus*. Forewing dark brown, densely and finely strewn with whitish-grey, with but one feeble antemedian line; at the cell-end a light spot and behind it a curved dark brown line from the costal margin to the inner margin; a submarginal bent light grey band from the apex to the anal angle; hindwing reddish-brown with 2 feeble brown lines. Expanse of wings: ♂ 2.4, ♀ 3 inches. South-Eastern Peru. S. Domingo, at an altitude of 6000 ft.

2. Genus: **Thelosia** Schs.

Very near to *Apatelodes*, distinguished by the somewhat more produced, more pointed apex of the forewing and the rounded or straighter, on 5 produced distal margin. Neuration exactly as in *Apatelodes* or *Colabata*, but sometimes vein 9 of forewing is absent or it is stalked with 10 on 8. Hindwing of ♂ rounded with a straight costal margin, of ♀ more elongate.

Type: *Th. phalaena* Schs.

phalaena. **Th. phalaena** Schs. (141 d) ♂ above without any markings dark reddish brown; beneath duller brown, at the costal margins in both wings densely strewn with chrome, with black cellular dots and a brown distal transverse line. The ♀ is above dull brown with 2 darker brown almost straight transverse lines which are outside very broadly strewn with light violettish grey like the basal area and the thorax. Abdomen and hindwing light yellowish ochreous with an indistinct cellular dot and a brown postmedian line parallel to the margin. Brazil (Novo Friburgo).

camina. **Th. camina** Schs. is in the female very similar to *phalaena*, but the exterior line is bent from the costal margin to 2 from where it extends straight to the inner margin; the violettish-grey dusting is absent, the forewing is more fawn-coloured, finely strewn with a darker brown. Hindwing with an indistinct dark median line. The median area is sometimes prominently darker brown. Expanse of wings: 38 mm. Castro (Paraná). ♂ still unknown.

resputa. **Th. resputa** sp. n. (141 d). Forewing of ♀ on the very light yellowish grey ground densely strewn with brown with 2 very faint darker brown transverse lines, the anterior one slightly bent, broad, faded, the posterior one narrower, obliquer than in *phalaena* from close before the apex to the last quarter of the inner margin, outside edged somewhat lighter; between them at the cell-end a whitish discal dot. Hindwing light ochreous with a very faint median spot, the postmedian line parallel to the margin. Type: 1 ♀ from an unknown habitat c coll. STGR. in the Berlin Museum.

postflavida. **Th. postflavida** sp. n. (141 d). Thorax brownish-grey, abdomen ochreous. Forewing of ♂ on the light greyish-yellow ground densely strewn with blackish with 3 indistinct darker purple brown nebulous lines, the broadest close behind a faded discal spot, behind it another subterminal line. Hindwing lemon-coloured, two thirds of the inner margin transversely irrorated with blackish, with 2 black transverse shadows obliterating towards the costal margin and running parallel to the distal margin, the median one being strongest, the subterminal one much fainter. Type: 1 ♂ from Passa Quatro, Minas, Brazil in coll. J. ZIKÁN.

truvena. **Th. truvena** Schs. (141 c) ♂ light greyish-brown, finely strewn darker, with a straight brown antemedian line and a brownish shadow behind it; at the cell-end a small black dot with a straight brown line behind it; before the margin besides 2 very fine, rather indistinct lines with darker scales between them. Hindwing light fawn with 2 very indistinct brown transverse lines. South Eastern Brazil, Sao Paulo.

truncata. **Th. truncata** Schs. (141 e), described as *Trabala* also belongs to this place. Forewing of ♂ yellowish brown, with an indistinct basal and an irregular median brown transverse line; a stronger straight brown oblique postmedian line and behind it another feeble one. Hindwing brownish yellow with an indistinct brownish median line. Castro, Paraná. — **rectilinea** Dogn., according to the information by SCHAUS, is merely a local form of it, of a similar colouring, but behind the straight postmedian line we miss the following finer line; nor are the two feeble antemedian lines mentioned in the description. Bolivia (Songo).

jorgenseni. **Th. jorgenseni** Schs. (141 e) is similar though darker, particularly the hindwing. Forewing cinnamon-brownish, the basal area darker, at the cross-vein a small blackish-brown dot; the dark brown postmedian line is quite straight, with a fine somewhat wavy line behind it; another fine submarginal cucullate line from 7—2. Hindwing darker loamy brown, at the margin cinnamon-brownish with a feeble discal dot and a brown indistinct median line. Paraguay.

minois. **Th. minois** Schs. (141 e) is still much darker, deep red-brown, with very faint traces of a darker antemedian line, an indistinct discal dot and a stronger but also nebulous postmedian line which runs as in *jorgenseni*, though it is very feebly concave towards the margin; an antemarginal wavy line. Hindwing still darker brown with golden brown fringe. Brazil (Petropolis).

meldola. **Th. meldola** Schs. (141 e) would almost fit better to *Apatelodes*, but SCHAUS places it here. Forewing basally and at the margin grey, the median area bordered by two light transverse lines is dark reddish-brown, in it a fine oval light-encircled discal spot; subterminal area lighter reddish brown, between 5 and 6 a small light spot; the veins from the antemedian line to the grey marginal area distinctly light. Hindwing almost whitish, at the margin somewhat smoky. Castro, Paraná.

3. Genus: **Falcatelodes** gen. n.

Closely allied to *Apatelodes*, but separated by the quite different shape of the wings resembling that of the following genus *Drepatelodes* from which it differs in the stronger, *Apatelodes*-like structure and the different

neuration. Apex of forewing obtusely falciform. Distal margin very oblique with traces of a slight projection on 5. Hindwing with a long inner margin and a somewhat roundly produced anal angle. On both wings the lower cell-end is produced like a lobe, especially long on the hindwing, and it only despatches vein 4, whilst 3 rises far from it in both wings. 6 and 7 stalked in both wings. Only 1 species:

F. anava *Drc.* (= *laffonti* *Dogn.*) (141 d). Forewing fawn with a slight pinkish tint, dusted darker brown; a light almost straight antemedian and submarginal transverse band; in the median area 2 almost parallel somewhat faded brown transverse lines, behind them a fine, distally light-edged, towards the margin concave subterminal line with fine black vein-dots which, beginning from 5, are enlarged into small black dents; between 5 and 6 a submarginal triangular white hyaline spot; marginal area more darkened. Hindwing pale fawn with 2 oblique brown parallel transverse lines, inner margin darker haired; fringe especially in the lower marginal half very dark. Ecuador; Peru; Bolivia.

4. Genus: **Drepatelodes** *gen. n.*

Closely allied to *Apatelodes*, but the structure is weaker, the body smaller and more slender. Forewing at the costal margin bent towards the apex and terminating in a falcate point, the margin sometimes with faint traces of denticulation. On the forewing 6 is very shortly stalked with 7 + 8 and 3 + 4 (the latter not always), on the hindwing 3 + 4 and 6 + 7 rise on long stalks, 3 + 4 rising with 2 almost from the same place.

Type: *D. tanais* *Drc.*

D. tanais *Drc.* (141 e), originally described from 1 ♀ the type of which from the Berlin Museum could be examined, is brown with 3 almost straight oblique stripes, the two inner ones towards the base, the outer one towards the margin feebly bordered with a lighter shade; behind them follows a strongly undulate-dentate subterminal line rising directly before the apex, its dents on 2 and 3 almost touching the margin and between them receding in a bow. Hindwing with similar lines, subterminal line very irregular. Panama, Chiriqui.

D. friburgensis *Schs.* (141 c) is similar to *tanais*, with much more distinct blackish transverse lines, all 4 of them basally light-edged, not so straight, especially the 3rd somewhat concave towards the margin, the subterminal line hardly visibly notched, obliterated analwards. Hindwing towards the margin darker, the 3 lines rather indistinct. Novo Friburgo.

D. ostenta *Schs.* Forewing yellowish-reddish with a slight lilac shade, scantily strewn dark brown, with 3 fine dark brown oblique lines, the first antemedian one angular on the median vein, the second from close behind the centre of the costal margin to the centre of the inner margin, the third from $\frac{3}{4}$; at the margin a number of light oblique streaks outside bordered with blackish-brown from the end of vein 7, incurved to 4 and then straight to 2; at the cell-end a blackish spot. Hindwing in the basal third light brown, behind it darker brown with a lighter brown postmedian band. Expanse of wings: 36 mm. French Guiana.

D. umbrilinea *Schs.* (141 e) looks like *friburgensis*, lilac brownish, in the marginal area the forewing is of a purer grey, with fine white veins; transverse lines quite similar as in *friburgensis*, the median line more excurved below the costal margin, outside shaded darker brown, the third straight, the subterminal line more distinctly dentate, not so far incurved, i. e. nearer to the margin. Hindwing more greyish-brown. French Guiana.

D. trilineata *Dogn.* is very near to *umbrilinea* and to *tanais*, the ground-colouring without the lilac tint, yellowish reddish-brown, and the median line is quite straight, not bent below the costal margin. It may be only a form of *umbrilinea*, since it originates from the same habitat in French Guiana. Both have an almost entirely white under surface.

D. quadrilineata *Schs.* (141 e) is larger than the preceding ones, light yellowish-brown, with 4 almost parallel oblique lines, all of them inwardly bordered with a somewhat light colour, only the outermost slightly concave towards the margin. Hindwing still lighter, with a feeble median line, and between 3 and 6 with small dark submarginal spots. From the Rio Madeira (Brazil).

5. Genus: **Olceclostera** *Btlr.*

It shows exactly the same structure as *Apatelodes*, but the margin of the forewing is slightly dentate below 5, though often hardly noticeable. Hindwing not so round, but mostly somewhat prolonged at the anal angle, or if that be not the case, the margin is very little dentate. The genus contains quite a number of extremely similar and hardly separable, mostly insignificant grey species, also a North-American representative.

Type: *O. irrorata* *Btlr.*

- truncata*. **O. truncata** Wkr. (141 f) is the most easily discernible species; forewing above yellowish-grey with a slight olive shade and 4 lighter transverse lines, the first from the first third of the costal margin straight to the inner margin and like the second somewhat narrower and more indistinct line distally bordered with brown, the 3rd and 4th subterminally near together and between them with a darker filling; close behind the distal line between 4 and 5 a small dark brown spot, and above 5 a hyaline spot; fringe speckled somewhat darker. Hindwing darker brown with a light median line which is very distinct beneath. Rather common, from Brazil.
- irrorata*. **O. irrorata** Btlr. (141 f) is somewhat smaller, reddish-brown, with dark red-brown scales; and basally and in the proximal half of the inner margin strewn with large lilac-whitish scales, with 4 dark brown transverse lines, the first as in *truncata* inside bordered with lilac white, the second near behind it, somewhat wavy, and distally angled on 1; then follows a fine light cross-vein streak distally bordered with dark; postmedian line curved round the cell-apex, subterminal line angular between 5 and 6, with a hyaline spot behind it. Hindwing somewhat lighter and more reddish. Guiana; Amazons.
- amelda*. **O. amelda** Dyar (141 f) is somewhat similar to *irrorata* by the dense lilac-grey strewing on the brown ground, but the transverse markings are represented here by quite obsolete darker brown bands being only noticeable by less light strewing, one being antemedian, one postmedian, a very feeble subterminal one, and the fourth close at the margin which is hardly dentate here, the projection on 5 is also but little rounded. The hyaline spot is somewhat larger than in *irrorata*, sometimes there is below it another very small one. Hindwing red-brown, with a slightly darker subterminal line. Mexico (Zacualpan).
- cuyabata*. **O. cuyabata** sp. n. (141 f) resembles the following *bilinea*, but it is smaller, darker, and much more variegated owing to the coarser brown strewing; the two antemedian lines are more undulate, especially the outer one which is inwardly angled on the submedian fold and outwardly on 1; at the cell-end a whitish transverse streak; postmedian line behind the cell obtuse-angularly rounded, it is the strongest of the lines, closely followed by the very fine feeble subterminal line, behind it another undulate-dentate submarginal line; the small hyaline spot on 6 is almost quite absent. Hindwing lighter reddish-brown with a median line which is angled on 6, and a feebler subterminal line. Type 1 ♀ from Cuyaba (Matto Grosso) in the Berlin Museum.
- bilinea*. **O. bilinea** Schs. (141 f) shows quite similarly arranged lines as *irrorata*, but the ground is here a brownish light grey, the lines are fine and dark, not edged lighter, 2 somewhat feebler antemedian lines, the 3rd is exactly in the middle and more distinct and darker than the others, almost straight; subterminal line almost undulate-dentate; behind the small hyaline spot there is another line being dentate as in *amelda* and disappearing analwards, behind it the margin is somewhat darker grey. Hindwing light reddish-brown with 2 shadow-like darker transverse lines. Brazil.
- azteca*. **O. azteca** Schs. (141 f) is somewhat larger, bluish ash-grey, strewn with brown, between the two antemedian and between the two postmedian lines of a brighter brown; the two anterior lines are slightly undulate; at the cross-vein a black dot amidst whitish scales; postmedian line almost rectangular on 6, behind the subterminal line especially analwards somewhat more intensely strewn with whitish; behind the yellowish hyaline spot an undulate-dentate short submarginal line disappearing analwards in a whitish brightening. Hindwing light red-brown, in the inner-marginal half and at the distal margin broadly darkened, with 2 rather distinct median and postmedian transverse lines. Mexico and Guatemala.
- avangareza*. **O. avangareza** Schs. (141 g) is extremely similar to *azteca* and probably only a form of it; somewhat smaller, lighter, the transverse lines nearer together, the ground between them less contrastingly brown, the black discal dot absent: the undulate-dentate submarginal line is more distinct and continued to the anal angle; apex of the wing somewhat sharper, like the marginal dents, too. Hindwing lighter brownish. Costa Rica.
- angelica*. **O. angelica** Grt. (= *hyalinopuncta* Pack.) (141 g) is in the male somewhat more slender than the preceding species, the abdomen is longer. Forewing light ashy grey with 2 nebulous light brownish slightly undulating antemedian and postmedian transverse bands; the anterior one has before it one dark dot each on the median and submedian fold, the posterior one behind it a row of vein-dots, which are connected by more or less distinct brownish undulate lines; then follows another very feebly marked brownish subterminal band and subapically a quadrangular and below it a smaller triangular, distally finely brown-edged hyaline spot; fringes brown, at the ends whitish. Hindwing brownish-grey with a feebly darker median line and distally light-edged postmedian line. Atlantic States. — **indistincta** H. Edw. is somewhat more brownish, more coarsely strewn and with quite obsolete transverse markings. Florida. — **seraphica** Dyar differs in the less deeply dentate distal margin, smaller hyaline spots, the upper one of which sometimes disappears altogether, and the grey, not brownish, feeble transverse bands; hindwing also greyer and without any reddish tint. Texas. — The larva of *angelica* is grey with a brown head: on the body fine black longitudinal lines assuming a V-like shape on the dorsum of the segments 5–10 and enclosing 2 small yellowish-green elliptical spots; the head is covered by the long whitish and brown, anteriorly projecting hair; between the long white hairs which are in places densely arranged like brushes there are single shorter stiff red bristles. The larva lives on ashes and lilacs.

O. bifenestrata Schs. (141 g) is probably a southernmore representative and hardly specifically different, *bifenestrata*. It is distinguished by a more complete (at least in the costal-marginal portion) black fine antemedian line, the nebulous band behind it being grey, hardly brownish, and much narrower; at the cross-vein there is often a black dot; the postmedian grey nebulous band is very narrow, too; fringe at the ends of the veins lighter speckled. Hindwing blackish-brown, at the margin darker. Described from Costa Rica, also from Rio de Janeiro and Sa. Catharina there are numbers of similar forms before me, thus apparently widely distributed.

O. maya Schs. (141 g) may be the somewhat more differentiated Mexican intermediate form between *maya*. the two preceding ones. Smaller, of a soft light grey, very scantily strewn with black, the hardly darker grey transverse bands as in *bifenestrata*, the postmedian one outside more distinctly defined by a blackish notched line, at the cell-end with a fine black dot; subapically only a hyaline spot; fringe only between 2 and 4 blackish-brown. Hindwing light reddish-brown. Jalapa; Colima.

O. magniplaga Schs. (141 g). Also like *maya*, somewhat larger, slender, apex of forewing more produced, *magniplaga*. the margin below the angle somewhat more oblique; marked like the 3 preceding species, but easily discernible by the reddish-brown marginal spot forming the exterior border of the undulate-dentate submarginal line and occupying the whole marginal area down to 2, being broadest between 4 and 6, where it borders on the large quadrangular hyaline spot. Hindwing reddish-brown. Panama; Costa Rica.

O. nigripuncta Schs. (141 g) belongs to the same group and is recognizable by the black inner-marginal *nigripuncta*. spot forming the lower end of the antemedian band; the two nebulous bands are chiefly darkened in the costal-marginal portion, especially the postmedian one in the costal-marginal third behind the cell; moreover, the markings are rather extinct except the postmedian row of vein-dots; the subapical hyaline dot is very small, below it another small blackish spot; the ends of the fringes are blackened. Hindwing brownish-grey. Guatemala; Costa Rica.

O. interniplaga sp. n. (141 h) is similarly marked as *nigripuncta*, but at once discernible by the two *interni-* deep blackish-brown large inner-marginal spots each of which forms the end of the two darker transverse bands; *plaga*. ground-colour ochreous brown, in the ♀ more red-brown; in the latter the whole antemedian band is darkened blackish, the distal margin being very strongly notched. Female type from Arouary (Cayenne), male type from an unknown habitat, both in the Berlin Museum.

O. reperta Wkr. (141 h) is somewhat similar, but the two inner-marginal spots are absent, the *reperta*. ground-colour is more a coppery red-brown, strewn with lilac whitish, the margin is much less strongly notched; the anterior faded transverse band is very broad, tinted purple, the posterior one is narrower, hardly curved round the cell-end, in *interniplaga* very strongly so; the other markings are the same. Hindwing reddish-brown. Guiana; Brazil.

O. basifusca sp. n. (141 h) is allied to *reperta*; ground-colour greyish-brown without a red tint, the whole *basifusca*. basal area as far as the exterior edge of the black antemedian band, which is more oblique than in the other species, densely strewn with black; the interior border of the antemedian band is distinct and irregularly notched, projecting with a pointed tooth on the median vein towards the margin; postmedian band more intensely blackened only at the costal and inner margins, at the inner margin it approaches the anterior band; marginal area with hardly any markings, the hyaline spot quite yellowish-green, oblong-quadrangular, outside bidentate; fringe black, crossed light on the veins. Hindwing blackish-brown with a reddish reflection, beneath greyish-brown, irrorated, with a black discal dot, a brown median line which is angular between 5 and 6, and an undulate-dentate subterminal line. Type: 1 ♂ from Campo Bello (Rio de Janeiro) in the Coll. ZIKÁN.

O. microps Wkr. (141 h) is a more common species. Forewing on the light reddish-brown ground densely *microps*. strewn with brown and coarsely with light lilac grey, below and behind the cell-end the light ground-colour is somewhat more prominent; antemedian line fine, irregular, black, below 1 removed towards the margin, behind it a hazy greyish-brown transverse band; at the upper cell-end a fine black dot; postmedian line greyish-brown, behind the cell and submedianly excurved, between basally concave, between this line and the undulate subterminal line a few black vein-dots; hyaline spot light greenish, quadrangular, outside concave, finely encircled by black, behind and below it traces of a dentate short submarginal line which is mostly somewhat broader rusty brown below the hyaline spot. Hindwing brownish, lighter in the basal half of the costal margin, with 2 dark, median and postmedian transverse lines, the latter beneath not denticulate. Brazil.

O. amoria Drc. (141 h), well figured in the Biologia, is very near to *microps* and the following *indentata*; *amoria*. larger and more slender than *microps*, and of a light reddish-brown ground-colour, scantily strewn with grey, the light brown bands as in *microps*, with a black cellular dot and a white subapical hyaline spot. Hindwing reddish brown with a narrow brown postmedian line. Fringe darker brown. Central America to Ecuador and Brazil.

O. indentata Schs. (141 i) is extremely similar to *microps*, somewhat larger and more slender on an *indentata*. average, looking somewhat lighter owing to its being less strewn, especially in the discal area; antemedian band more oblique, more notched in its exterior border, both the bands brighter reddish-brown at the costal margin;

the hyaline spot more elongate and outside deeper concave. Hindwing darker brownish-grey, beneath the distal transverse line is finely crenulate. Guatemala; Costa Rica; a somewhat smaller and beneath greyer and more monotonous specimen from Colombia (Muzo).

guanduna. **O. guanduna** *sp. n.* (141 i) is likewise near *microps*, but much more variegatedly spotted and easily discernible by whitish scales being accumulated at the cross-vein and by a transverse row of white subterminal dots arranged outside on the black vein-dots; the two median lines are much closer together, the posterior one is less curved; the first antemedian line is much more notched than in the preceding species; marginal area more profusely strewn with white. On the quite pale yellowish sand-coloured hindwing only the inner-marginal portion and a marginal band are broadly darkened brownish-grey, 2 feeble transverse lines are not angled below the costal margin as in the preceding species, but slightly bent. Beneath the forewing is almost yellowish-white, the hindwing densely and coarsely strewn with dark brownish-grey, the veins whitish, the transverse lines much stronger than above, obtusely angular on 5, the distal one outside bordered with white. Type: 1 ♂ from Guandu (?) (Espiritu Santo) in the Berlin Museum.

mutusca. **O. mutusca** *Schs.* (141 i) is above lighter grey than *microps*, only very scantily strewn with black, at the apex darkened, with the usual 2 transverse bands, the interior edge of the basal one and the exterior edge of the distal one marked by some black vein-dots, behind the latter another notched subterminal line; hyaline spot small, round, yellowish, below it mostly a tiny black spot. Hindwing brownish with 2 transverse lines, the interior line faded and more reddish than the exterior, more distinct, blacker line. Beneath discernible by the very strongly notched exterior transverse line of the hindwing. Rio de Janeiro.

castrona. **O. castrona** *Schs.* (141 i) is smaller, light grey, scantily strewn with black, in the costal-marginal portion also with some red-brown scales; both the antemedian and postmedian transverse lines are very close together so that they almost look like double lines without any brownish filling between, only at the costal margin their beginnings are somewhat broader red-brown, the two postmedian lines at the costal margin like 2 oblique costal-marginal streaks, behind them a small red-brown triangular spot representing the beginning of the otherwise quite extinct submarginal line; hyaline spot very small. Hindwing light brownish, 2 transverse lines hardly noticeable. Beneath very pale brownish, the hindwing somewhat more coarsely strewn with black, both wings with 2 extinct transverse lines, the interior one on the hindwing broader and more red-brown, the exterior one strongly notched. Castro (Paraná).

castra. **O. castra** *Jones*, described from a ♀, was not before me. Forewing ochreous, strewn with blackish-brown, especially costally and in the marginal area; a faded dark blackish-brown antemedian line is very strongly undulate, the similar postmedian line less distinct, behind it a dentate subterminal line; margin ochreous, fringe blackish-brown; at the cell-end a large round blackish-brown spot, the hyaline spot between 5 and 6 small. Hindwing glossy ochreous with 2 postmedian lines, the interior one red-brown, the exterior one more distinct and blackish brown. Beneath on the ochreous forewing with a brown cellular shadow being darkened on the cross-vein, and an undulate brown postmedian line; hindwing marked as above, but more intensely strewn dark and with a discal dot. Expanse of wings: 35 mm. Castro Paraná.

brama. **O. brama** *Schs.* (141 i) is above separated from the preceding species by the red-brown colour and its larger size: forewing strewn with a darker purple brown, especially in the basal third, the broad antemedian band still darker; at the cross-vein there is a small black light-edged spot; postmedian line of the usual shape, behind it at the costal and inner margins one small dark spot each; the undulate-dentate subterminal line on the inward dents intensified by black vein-dots; the subapical hyaline spot is yellowish, outside indented, below it often with a small black spot. Hindwing dark red-brown with 2 feeble transverse lines the distal one of which is crenulate beneath. Colombia; also from Sa. Catharina.

oriunda. **O. oriunda** *Schs.* (141 i). Forewing dark ochreous, with brown transverse bands, the interior one basally distinctly bordered with black, outside faded, the exterior one on the contrary outside distinctly notched, inside faded; between the bands a black discal dot: below the small hyaline spot a black spot in which there is often another small hyaline spot. Hindwing coloured like forewing, with 2 transverse lines. Maroni R., French Guiana.

ibar. **O. ibar** *Schs.* (141 i) is quite different; body light sand-coloured, head and thorax suffused with olive-grey, abdomen with lighter rings. Forewing light sand-coloured, dusted with light olive-grey, with double sandy brown antemedian and postmedian lines, the latter finely bordered with a darker colour, the outer line on 5 distally angular; the light subterminal line runs straight from the costal margin before the apex to the anal angle, before it at the costal margin a dark brown triangular spot, and behind it above vein 5 a black dot; apex pointed, almost falcate, the margin slightly dentate. Hindwing with a cinnamon-reddish tint with a slightly darker median band, bordered by a dark median and a light postmedian line. Beneath the forewing is without the antemedian line; hindwing bright, median band brown, outside distinctly bordered with white. From Cordoba (Argentina), described according to a ♀.

6. Genus: **Thyrioclostera** *gen. n.*

The only representative, originally described as a *Callopietria*, by DRUCE as *Carthara*, would match very well *Olceclostera* by the shape of the wings, but the neurulation is different. According to SCHAUS who

examined the type, vein 2 of forewing rises behind the middle of the cell, 3 and 4 on a distinct stalk, 5 comes from the centre of the cross-vein, 6—10 are stalked, and 11 rises near the cell-end. On the hindwing 3 and 4 on a short stalk, 6 and 7 on a longer one. Only 1 species.

Th. trespuntada Dogn. (= *bifasciata* Drc.) (141 i). Forewing chestnut-brown, in the discal area darker, *trespuntada*. with 2 whitish antemedian and postmedian transverse lines, the latter feebly S-shaped; at the cell-end there are 3 silvery dots in a triangle; veins of marginal area distinctly light, at the costal margin before the apex a light-edged triangular spot. Hindwing hardly lighter red-brown, at the anal angle lighter yellowish-grey, above bordered by blackish. Peru; Ecuador.

7. Genus: **Colabata** Wkr.

Forewing shaped as in *Apatelodes*, but the margins of the wings are dentate; neuration also similar; in the ♀ forewing 9 + 10 stalked with 8, whilst the ♂ often lacks vein 10. Shape of hindwing generally rounded.

Type: *C. lineosa* Wkr.

C. marginalis Wkr. (= *lineosa* Wkr.) (142 a). Ground-colour of forewing light yellow, but dusted with *marginalis*. bronze brown excepting the base and marginal area, at the costal margin and in the central area strewn with lilac whitish, with a dark, light-edged discal spot; with 2 fine brownish-grey antemedian and 2 postmedian lines, the first being strongly notched, the second almost rectangularly bent below the costal margin, the third the same on 5, the fourth undulate-dentate; in the yellow marginal area another regularly deeply dentate cucullate line. Hindwing in the disc hues with light brownish, with 2 median lines, the interior one strongly curved. The much larger ♀ is lighter yellow, less brown, and not at all dusted with lilac white. Brazil.

C. mendozata Dogn. (142 a) is very similar to *marginalis*, on an average somewhat smaller; ground- *mendozata*. colour the same, the median area and particularly the costal margin lilac white; the two postmedian lines are more separated, especially at the costal margin; the marginal area is hardly lighter yellow than the brass-brown subterminal area, therefore the marginal dentate line is much less distinct than in *marginalis*; the discal spot of *marginalis* is absent. Hindwing very similar to that of the latter species. Argentina and Paraguay.

C. thea Schs. (142 a) is likewise very closely allied to the preceding species, but easily separated by the *thea*. much sharper angle on vein 5 of the forewing with a distinct concavity above it and a more distinctly notched distal margin; colouring almost the same, but instead of the brass or bronze brown strewn much less strewn with brownish grey. Median area only whitish at the costal margin; at the cell-end a white transverse streak enclosing a small dark dot; the transverse lines, especially the second and third, are straighter, the third forms a sharp right angle on 5. On the less reddish-hued, more grey-dusted hindwing the transverse lines are more distinct. Argentina.

C. basifulva Kaye (142 a) resembles the ♀♀ of the preceding species, but by the shape of the wings it *basifulva*. forms the transition to the two following species. Forewing light ochreous, especially basad and subterminally strewn with red-brown, with the usual transverse lines; at the cell-end a dark streak. On the yellow hindwing a dark discal line is united at the lower cell-end with the postmedian line. Trinidad; surely only a form of *marginalis*.

C. ephora Cr. (= *uzita* Drc.). Forewing yellowish ochreous, basally and subterminally but little strewn *ephora*. dark, the antemedian band straighter than in the preceding species, on the whole distally concave, only on the median somewhat distally angular; postmedian band much less curved and the notched line behind it towards the costa less distinct, subapically a nebulous band behind it; submarginal notched line as in the other species. Hindwing with 2 coppery red-brown nebulous bands. Guiana.

C. lybia Drc. (142 a) is very much like *basifulva*, less strewn, excepting the costal marginal portion, *lybia*. the transverse lines almost exactly as in *marginalis*, between them a dark spot in a yellow halo at the cell-end. Hindwing light yellow with 2 reddish-brown nebulous bands, the exterior one near the margin, the interior one thinner, almost rectangularly rounded on 6. Panama to Brazil. Southernmore specimens are mostly more strewn and form the transition to — **nubilosa** Dogn. (142 b) which I do not consider to be a separate species, *nubilosa*. just like the last 3 species, anyhow. In *nubilosa* the ground-colour is more bony white, more densely strewn with red-brown, the darkest subterminally at the costal margin where it represents a square dark costal-marginal spot. French Guiana. — Still much darker, at the same time also larger and with broader wings is — **hoppi** f. n. *hoppi*. (142 b), from Chachatoy (Colombia); here almost the whole wing is strewn with purple brown, intermixed with lilac white scales, the ground-colour showing through deeper ochreous, the purest near the small discal dot and in the lower half of the marginal area. Hindwing more extensively suffused with red-brown, before the subterminal broad nebulous band separated by a narrow light interspace with a fine line. Types ♂♀ in the Coll. HOPP-Charlottenburg.

dora. **C. dora** Schs. (142 c) is smaller and apparently rather variable, the light yellow ground irregularly strewn with greyish-brown, in the middle costal-marginal portion also somewhat whitish; both the antemedian transverse lines irregularly notched, both the posterior ones strongly undulate-dentate; the exterior one outside bordered with light yellow; at the cross-vein a small black dot in a light yellow halo; subterminally a light yellow though also slightly strewn undulate line, and before the margin the usual fine black cucullate line; distal margin strongly dentate. Hindwing densely suffused with brown, the lines as in *hoppi*, i. e. before the subterminal band with a fine line besides. Brazil.

liliana. **C. liliana** Schs. (= *jucunda* Dogn.) (142 b) differs from the preceding species in the colouring and marking. Ground-colour bright ochreous, almost rusty yellow, with 3 fine rather straight transverse lines which are basally broadly bordered with pinkish lilac like the greatest part of the median area; at the cell-end a small strigiform spot in a light oval halo; the antemarginal dentate line approaches the margin on 2 and 5 more than on the other veins. Hindwing with greyish-brown nebulous bands as in *dora*. Brazil, Novo Friburgo.

hezia. **C. hezia** Drc. (142 c) is marked similarly as the preceding species, but the rusty yellow ground-colour is only traceable in the basal portion, the rest of the wing being densely dusted with greyish-brown, without any pinkish lilac tint; antemedian and postmedian transverse lines somewhat more curved than in *liliana*, the anterior one inwardly bordered with chalky white like the costal margin which is triangularly expanded in the middle and comprises the discal dot; the posterior transverse line is finely undulate and on both sides narrowly bordered with white; median line absent, instead of it a feeble grey shadow extends from the lower cell-angle to the centre of the inner margin; the antemarginal cucullate line is far remote from the margin and feebly dusted with white. Hindwing brownish-grey with whitish ends of the fringe and indistinct blackish nebulous bands. Antennal shaft white, pectinations blackish-grey. South-Eastern Peru.

illauta. **C. illauta** sp. n. (142 c) is smaller and more slender than the preceding species, but with broader wings, a pointed apex and a slight concavity below it and a convex distal margin, scarcely dentate. Forewing of ♂ on the tan-coloured yellow ground throughout strewn with blackish-brown, with 2 almost straight transverse lines edged with white as in *hezia*, and a feeble median line between them passing outside close by the black discal dot to which a chalky white spot is appended below; costal margin, especially in the distal half of the median area strewn with white; submarginal cucullate line as in *hezia*. Hindwing light yellowish-grey with a broad postmedian nebulous band of blackish irroration. The ♀ is almost quite light yellow, strewn scarcely darker, the transverse lines more distinct and more broadly edged with white. According to a couple from Passa Quatro (Minas), Brazil; types ♂♀ in the Coll. J. ZIKÁN.

8. Genus: **Zanola** Wkr.

Distinguished from the other genera by the costal margin of the hindwing being straight or concave and showing an indenture before the apex. Neuration exactly as in *Apatelodes*, but shape of wings generally broader. In the ♂ the distal margin of the forewing is not or hardly concave below the apex, and below it more or less dentate.

Type: *Z. difficilis* Wkr.

verago. **Z. verago** Cr. (= *difficilis* Wkr., *vivax* H.-Edw., *harpis* Drc.) (141 k, 142 c) ♂ of a very variable ground-colour, the yellow ground being strewn with brownish-grey, more or less violet or red-brown; of the purest yellow is a spot below the cell behind the antemedian line and 2 subterminal spots in the upper half of the wing; costal margin mostly rather broadly dusted with lilac white; the dentate transverse lines usually vanish in the dark-strewn ground; a small discal streak in a light oval. Hindwing densely strewn like forewing, excepting the somewhat yellow marginal portion. The larger ♀ is almost purely yellow, little strewn. Under surface variegated, especially the hindwing of a bright lilac, with 2 feebly dentate transverse lines. Mexico; Venezuela; Surinam.

impedita. **Z. impedita** Dogn. (141 k) is above extremely similar, but it also shows a concave indenture below the apex of the hindwing, and it is at once discernible by the 2 very strongly dentate transverse lines on the hindwing beneath; the other marks of distinction stated by the author, i. e. the postmedian line touching the subterminal line at the anal angle, does at least not prove correct in the specimens before me from the same takings from Mt. Tolima. Colombian Central Cordilleras, Mt. Tolima.

aegina. **Z. aegina** Cr. (141 k) has narrower wings than *verago* and is much more uniformly and densely dusted with dark red-brown, basally and in the lower two thirds of the marginal area with a slight rusty yellow shine, on the veins and in the apical portion of the costal margin dusted with bluish; the notched transverse lines are little prominent in the dark ground; at the cell-end a red-brown discal spot pupilled yellow above; the usual antemarginal cucullate line; fringe white, on the ends of the veins broadly blackish-brown. Hindwing monotonously dark red-brown, with white fringe, only apically with a slight rusty yellow shine, below the apex with a deep indenture. Guiana.

elongata. **Z. elongata** Schs. (141 k) is similar to *aegina*, but it has longer and narrower forewings with a more oblique distal margin which is much less dentate, which, however, may only look so owing to the absence of the

fringe; moreover, coloured and marked as *aegina*, but the apex is rusty yellow as far as the tip. Hindwing more rounded without the indenture below the apex, blackish-brown with a whitish apical spot. Described according to a ♀ from Costa Rica (Tuis).

Z. fieldi Schs. is smaller. Body above dark reddish brown, beneath reddish yellow, abdomen with *fieldi*. oblique brown lateral streaks. Forewing dark brownish-grey, costal margin and basal third below the cell dull reddish-brown; dark antemedian, median and postmedian lines marked from below the subcosta; at the cross-vein a reddish-yellow streak of scales; a fine dark subterminal line is distally arcuately dentate, an antemarginal line reversely so, between 4 and 5 before it a reddish-yellow spot; at the anal angle a light brown shadow. Hindwing dark brown, above the cell and 6 reddish-brown, at the costal margin in the middle whitish. Expanse of wings: 30 mm. Costa Rica.

Z. lychnica Dogn. (141 k) is a very small species looking like a small *verago*. Forewing lighter and darker *lychnica*. red-brown with a fine white antemedian line which is inwardly shaded darker brown and outside rusty yellow; at the cell-end a dark streak in a whitish oval, above it white dusting at the costal margin, below it a dark median shadow; a fine white postmedian line forms a large bow round the cell; behind the antemarginal cucullate line small reddish-yellow marginal spots, the largest of which recedes between 6 and 4 as far as the postmedian line. Hindwing monotonously light brown. Peru (Upper Madre de Dios).

Z. poecila sp. n. (141 k) is somewhat similar to *lychnica*. Forewing brownish-grey, in the basal third *poecila*. and apically rusty yellow, — the thorax is more or less rusty brown, too — with 3 fine black transverse lines, the antemedian one inside bordered with lilac white, the white colour separated at the costal margin in the shape of a V; veins fine black; at the cell-end a black discal streak in a reddish white oval, behind it follows a fine black postmedian line and somewhat farther outside a slightly curved subterminal line on both sides bordered with white which colour is expanded at the costal margin into a triangle and bends inwards from 6, the ground before it being darkened like a spot; the antemarginal cucullate line is only traceable at the apex. Fringe distinctly speckled black and white. Hindwing brownish-grey, at the costal-margin almost purely white, enclosing the beginnings of a brownish grey postmedian double line; at the cell-end a rusty yellow spot appearing also on the light brown under surface which exhibits 2 dark notched lines and a large costal-marginal spot. Type 1 ♀ from Passa Quatro (Minas), Brazil, in the Coll. W. HOPP-Charlottenburg.

9. Genus: **Compsa** Wkr.

Scarcely separable from *Apatelodes* and distinguished from *Zanola* by the straight, hardly convex costal margin of the hindwing. Forewing with a sharp apex of the wing and a rounded distal margin showing very faint traces of dents which are a little more developed in the hindwing. Neuration same as in *Apatelodes*.

Type: *C. saturata* Wkr.

C. saturata Wkr. (= *trilunula* H.-S.) (142 c). Scheme of marking and colouring exactly that of the *saturata*. preceding species: forewing dark red-brown, in the basal third and subterminally more or less lighter, at the apex almost rusty yellow; the blackish-brown, undulate-dentate antemedian and postmedian transverse lines on the averted sides bordered with a lighter rusty yellow colour; before the margin the usual cucullate line which is only clearly prominent in the yellow apex; the exterior half of the median area is crossed by a lead-coloured transverse band traces of which appear also behind the antemedian line. Hindwing blackish-brown, before the anal angle with an oblique rusty yellow patch. The much larger ♀ is more clearly outlined reddish-yellow and yellow, and it shows a yellow spot also at the anal angle of the forewing. Brazil.

C. felderi Drc. (142 d) is of a more slender build, with broader wings, lighter red-brown than *saturata* *felderi*. and more uniform, without the contrasting yellow; the transverse lines in the ♂ set with silvery white spots, the largest at the posterior line below the submedian fold; in the disc a circular black-centred ochreous spot. In the ♀ the postmedian line is more a narrow silvery white line on both sides edged with blackish-brown. Hindwing lighter than in *saturata*. Mexico to Costa Rica.

10. Genus: **Carnotena** Wkr.

This genus is founded upon but one small species and is hardly tenable; in my opinion it is rather coincident with *Colabata*; as to its structure I am unable to give any particulars, since I am only in possession of a sketch kindly made by Mr. TAMS, according to which the scheme of markings agrees exactly with that of *Colabata*; the margins of the wings, accordingly, are not dentate. The species was hitherto taken to be a Geometrid, but according to TAMS it belongs here; it was once more described by WALKER as *Aspilates*.

C. xanthiata Wkr. (= *perlineata* Wkr.) (141 k) is above golden yellow, on the forewing with 5 red *xanthiata*. transverse lines, both the antemedian ones angular below the costal margin, the exterior one and the postmedian line being crenulate, between them a small discal dot; the subterminal and antemarginal lines are dentate and united above the anal angle. Hindwing somewhat paler with 2 feeble transverse lines. Amazons, Ega.

12. Family: Saturnidae.

In conformity with the enormous number of *Saturnidae* occurring in America — about 750 forms being known today — we are met with most varied shapes. We were hitherto accustomed to consider the *Ceratocampidae* or, as they are called today: *Syssphingidae*, as an independent family. HAMPSON, according to his dividing principle, believed to have found a good means of division in the absence of the proboscis and tibial spurs of the *Saturnidae*, whereas they are present in the *Ceratocampidae*. But we shall directly see that, considering our present knowledge of the abundance of forms, this is not sufficient, the boundaries becoming more and more effaced, so that one may ad lib. range the boundary-forms here or there. Since PACKARD found that the large *Arsenura*, *Dysdaemonia*, and their allies can neither be assigned to the genuine *Saturnidae*, as was customary, JORDAN has closely investigated this group and, in meritorious works, comprised the insects as the superfamily of “*Saturnioidea*”, subordinating the various groups as families. We follow here his example, but in order to conform with the scheme of this work we comprise the whole as a family and, considering the evidently very great relationship, we subordinate the genuine *Saturnidae* (with the subordinate groups of the *Attacinae* and *Saturniinae*) and the *Syssphingidae* (with the 2 subordinate groups of the *Arsenurinae* and *Syssphinginae*) as subfamilies, to which also in America the quite heterogeneous *Oxytenidae* and *Cercophanidae* are attached as two more subfamilies.

JORDAN found the only incontestable mark of distinction between the *Saturnidae* and *Syssphingidae* to be a small parasternum in the mesosternit of the *Saturnidae*, whilst that of the *Syssphingidae* is large. Moreover there is a biological difference, the *Saturnidae* chiefly having larvae with fleshy warts or stellately haired or spined knob-like warts and spinning a cocoon, whereas the *Syssphingidae* mostly exhibit long fleshy spines on the first and last segments only in their youth, being later generally bare, and the metamorphosis taking place in the soil without a cocoon. The latter, however, is not always the case, since the group of *Telea-Tropaea* the exterior of which is entirely like that of the *Saturnidae* spin cocoons, whereas, anatomically, they belong to the *Syssphingidae*, being another evidence for the obliteration of the boundary between the two subfamilies.

As in all other faunal regions, so in America the *Saturnidae* also number among the most magnificent Moths often attaining quite a respectable size. The colouring and marking are likewise very similar on the whole to that of the well-known types from other parts of the globe, and we are everywhere met with parallel forms corresponding to the other faunae; among the *Attacinae* the numerous *Rothschildia*-forms are particularly remarkable, representing rather true images of the Indian *Attacus*; exactly as in other continents we find the green, long-tailed *Tropaea* corresponding to the *Actias*, whilst the *Telea-Melosamia* group is quite similar to some *Antheraea*. In the Volumes X (p. 497) and XIV (p. 313) we have pointed out other parallel features. On the other hand, however, quite a number of remarkable representatives cannot be compared with any other groups; as for instance the *Dirphia*-group, the *Hemileucidae*, *Hylesia*, and among the *Syssphingids* the isolated *Rescynthis*, *Arsenura*, and *Dysdaemonia*, as well as the very strange species of *Copiopteryx*. Nor are the *Eacles*, *Citheronia*, and *Adelocephala* comparable with any other forms.

In the Introduction to the Indian Part, it has already been pointed out that the *Saturnidae* are undoubtedly a very old group adhering, with a certain rigidity, to the same design of marking, the eye-shaped central spot between 2 transverse stripes, which we also find in America in the very same way, especially well expressed in the genus *Automeris* in which the eye, being confined to the hindwing, often exhibits the most magnificent colouring. Besides the characters of marking, it is also in America the great distribution which makes us presume that the *Saturnidae* are extremely old. We find them from the north-western territory down to the

southernmost parts of Chile, where the re-occurrence of northern forms after crossing the southern tropic is less conspicuous than is the case in Africa, where it marks a most characteristic feature. It is just in Argentina and Chile, where we still come across very remarkable and variegated representatives both among the real *Saturnidae* (*Polythysana*) and among the *Syssphingidae* (*Dysdaemonia fosteri*), although the number of forms decreases considerably to the north and south. The tropics of America certainly contain the greatest variety and an incredible abundance of species.

Real protective colourings are less common with the American forms than for instance in the African Region, where it is an especially characteristic feature of the *Carnegia* and *Ludia*. Beside the peculiar *Neocarnegia basirei* which resembles a crumpled withered leaf with many holes in it, there are only the green forms of *Tropaea* which are rather imperceptible among the green leaves. Moreover, we may mention yet the *Lonomia*-species copying yellow or brownish leaves provided with rusty or spore-like spots, mostly even with a brown median vein, as well as most of the *Automeris* which look like withered leaves, when at rest.

By far the most of the *Saturnidae* are "defiant forms" which, by means of their often strikingly developed frightening eyespots, are undoubtedly able to frighten off small-sized enemies. If one has seen, for instance, the large *Automeris metzli* opening and closing its hindwings on being disturbed, as butterflies do, and displaying the enormously developed eyespot, one may easily imagine that to a certain degree it is protected by this and still more so by its large size.

Of the larvae of the American *Saturnidae* we know relatively much, quite a number of them having been bred in Europe and being, therefore, well known. The larvae of *Automeris* are apparently particularly protected by their often very effectively burning hairs. The larva of *janus*, for instance, is enveloped in so dense a prickly armour of horribly burning hairs that it may cause very dangerous injuries. As in other faunal regions we also often find here very brightly variegated warning colours, the insects frequently being green with variegated warts on black belts.

A unique position is occupied by the *Syssphingid* larvae, above all the *Arsenurinae*. We find here the same or quite similar conditions as were described with the family of the *Brahmaeidae*. They are remarkably soft animals, in their youth with large horns in front and behind, which mostly disappear with their later moults. The best example for this group is the well known "hickory-devil" (cf. picture on cover).

The food-plants of the American *Saturnidae* are chiefly all kinds of foliage-trees, frequently fruit-trees. Already in the Indian Part it was mentioned that, for instance, the larva of *Pl. cecropia* occurs on many species from about 20 different families of plants, being thus extremely polyphagous. Wherever large species occur in great numbers, they may, owing to the great voracity and the quick growth of the larvae, defoliate whole trees and forests. This, however, is not only known of the large species of *Samia* and *Telea*, but also smaller animals, such as some *Hylesia*, e. g. *H. nigricans* Berg from Argentina, may do enormous damage to fruit-trees or willow plantations. There are, however, also herbivorous larvae, for instance among the *Hemileucidae* a whole group living on grass, which may sometimes devastate pasture-land, if they occur in great numbers, as it was ascertained for *Euleucophaeus oliviae*. The quite different *Oxytenidae* live on Rubiaceae. The *Saturnidae* apparently do not live on real poisonous plants, as has also been ascertained in reference to the other faunal regions.

Many species are known to live gregariously in their larval stage, for instance several species of *Hylesia*, some of which set out in lines in search of their food like our processionary caterpillars, in order to return again to their common nest. Others, such as *Dirphia gregatus*, build a solid nest similar to that of the Pierid *Eucheira socialis* (Vol. V, p. 55) in the shape of an oval bag of 15—20 cm length, which being open at both ends, is fastened to the end of a twig with a stalk and to which adjoining leaves are drawn; in this nest also the pupation takes place in separate cocoons.

The way of pupating does not differ from the usual scheme, as far as the genuine *Saturnidae* are concerned, all of which build cocoons of a rather coarsely or densely matted meshwork which is often even wrapped up in leaves and, in certain species, suspended on a thread. No American species supplies really useful silk, it has occasionally been tried to utilize the cocoon-silk of *Ph. cynithia* and *C. promethea*, but it cannot be reeled off. With the exception of the *Telea* and *Tropaea*, which are externally and also biologically very closely allied to the *Saturnidae*, the *Syssphingidae* pupate without a cocoon naked in the soil. The entirely different *Oxytenidae*, whose larvae recall Sphingid-like types, pupate with few threads between rolled-up leaves, whereas the *Cercophaninae*, more like the genuine *Saturnidae*, weave oval or more pear-shaped cocoons which are open at one or both ends.

The habits of the American *Saturnidae* are chiefly the same as in the other faunal regions. In the real tropic belt itself presumably all are more or less nocturnal, both the sexes being taken on the lantern at night. The farther one proceeds to the north or south, the more the ♂♂ fly in daytime, as for instance in North America the species of *Pseudohazis* and *Hemileuca* which are coloured like butterflies, and in Southern Chile particularly the conspicuously variegated *Polythysana* the ♂♂ of which keenly swarm about in search of the lazily seated ♀♀. IZQUIERDO has recently made studies on the attractive force of the ♀♀ of *P. edmondsi*; these insects behave exactly as for instance our *Orgyia*-species are known to do, since a great number of ♂♂ may be allured by a single virgin female.

Moreover, the *Heliconisa* occurring in Southern America are especially remarkable for the great sexual dimorphism, the ♂♂ with their hyaline wings dashing along in the sunshine and tracking the enormously stout dark-coloured females which are sitting hidden in the grass. In a very charming way J. F. ZIKAN has informed us of the innumerable ♂♂ of *H. pagenstecheri* whirling about in the air like the drift of large snow-flakes. Very differently coloured and marked are also the sexes of some *Dirphia*, such as those of the *tarquinius*-group, as well as some species of *Automeris* such as *flexuosa* or even the well-known *io*, many species of *Copaxa*, and especially among the *Syssphinginae* a great many species of *Eacles* and *Citheronia*. The *Syssphingidae* provided with a rudimentary proboscis very likely do not take up any food as imagines, whereas the *Oxytenidae*, which have a well developed proboscis and look exactly like Geometrids, probably do so, although we are hardly cognisant of their habits.

I. Group. Cell of forewing open (*Attacinae*).

1. Genus: **Philosamia** Grt.

Regarding this genus being quoted as *Samia* in Vol. II, p. 212, we may refer in general to the above mentioned place as well as to Vol. X, p. 503, where the genus and species has been dealt with at large. We merely repeat here the presence of a small proboscis without any function; antennae of ♂ and ♀ pectinate; in the latter sex hardly shorter. Abdomen above provided with several rows of woolly tufts; both wings with a crescentiform hyaline spot. Neuration otherwise not peculiar. The only species to be considered originates from the Indian fauna from where it was acclimatized both in Europe and — since 1861 — in North America.

Ph. cynthia *Dru.* This universally well-known lepidopteron with its ground-colour varying between *cynthia*. loamy yellowish and olive green or brown has been figured so very often that we only refer to the figures in Vol. II pl. 33 a and Vol. X pl. 52 c. The American specimens which were named — **advena** *Pack.* are not very *advena*. large and, particularly in the female, they have a thickset shape with obtuse wings, the colour being never very bright green. Especially in the region of the Atlantic coast the form is rather common in the neighbourhood of large towns. The white-hued, lighter or darker green larva exhibits 6 rows of bluish fleshy thorns and chiefly lives on *Ailanthus*, *Ilex*, *Sambucus*, but besides also on nearly all foliage-trees and shrubs. The silk gained from the cocoons is of little value, coarse, and cannot be reeled off but only carded. — The larva could be bred by the coupling of *cynthia* ♂ with *promethea* ♀, it is said to have exactly corresponded with the larva of *promethea*. According to STRECKER, this hybrid has also been observed as imago in nature and is said to combine the colour of *cynthia* with the discal marking and the shape of the wings of *promethea*-♀. According to the same author, the male obtained by breeding, however, is almost exactly like a blackened *promethea*-♀.

2. Genus: **Rothschildia** Grt.

The representatives of the palaearctic genus *Attacus* in America are a very homogeneous well characterized group of partly closely allied and often hardly differentiated species, particularly because the frequently wrong use of the names has caused dreadful mistakes and confusions; we have tried to disembroil as much as possible, and by the aid of Dr. JORDAN and SCHAUS, we believe to have attained some clearness in the right use of the names. They are large lepidoptera, the apex of the forewing, especially in the ♂♂, often somewhat falciform, though roundly produced, with a more or less triangular or, preferably in the ♀♀, oval hyaline spot on all the wings, situate between 2 characteristic transverse lines. Palpi short, antennae in both sexes pectinate, though shorter in the ♀♀. On the very broad forewing veins 2 and 3 rise rather distantly separated, the cell is open as in all the genera of this subfamily. Hindwing especially in the ♂♂ often extraordinarily long so that the comparatively slim abdomen does not extend to the centre of the inner margin, at the distal margin often somewhat concave, in the ♀♀ more rounded and shorter. Larvae stout, cylindrical, with short starlike arranged hairs on knob-shaped tubercles, not unlike the palaearctic larvae of *Saturnia*, or also without tubercles. They pupate in a frequently pear-shaped cocoon.

Type: *R. hesperus* L.

aurola. **R. aurola** Cr. (= *ethra* Oliv., *atlas* Oliv.) is one of the largest and best known species with a rather much produced apex of the forewing, collar predominantly brown, only in front and behind with a white line; antemedian line somewhat shortly, notch-like produced on the veins, the portion between the lower cell-edge and the inner margin rather straight, hyaline spot obliquely triangular, the proximal margin concave, the distal point extending into the strongly and irregularly notched postmedian line; characteristic are the very long and strong notches of the pinkish grey subterminal band. The pinkish-white subapical spot is outside defined by an almost straight white line, the black triangular spot behind it is large, on its outside a dark red narrow crescent; the black submarginal line forms very regular bows; hindwing of ♂ very long, in the submarginal bow there are small black bows turning reddish towards the costal margin. Southern Central America, but chiefly from Guiana. — *speculifer* Wkr. (102 b), according to the kind information by Dr. JORDAN, is the common South-Eastern Brazilian subspecies with somewhat shorter hindwings, otherwise differing little from the nomenclatural form, only being mostly somewhat darker, more chestnut brown in the ground-colour. — *andensis.* **R. andensis** Rothsch. is still much darker chestnut red in the median area, the metathorax also white like the basal abdominal band; the greyish pink subterminal notches still more distinct, the white postmedian line less strongly notched, its black interior border much less prominent; hindwing considerably shorter. From South-Eastern Peru at altitudes of 2 or 3000 m. Much farther to the north in Mexico, the species is represented by *roxana.* a very large, broad-winged form with a but slightly produced apex of the forewing: — **roxana** Schs. (102 a) of a very dark chestnut ground-colour, with larger, longer extended hyaline spots, the proximal margin of which is deeper concave, whilst the distal point extends beyond the white postmedian line which is but little notched; the dents of the subterminal band are also less developed. By the minute examination of the genital organs the specific difference may be found. The larva of *speculifer* is green with a somewhat lighter lateral stripe and small red tubercles. It lives on *Rieinus* and other plants.

chiris. **R. chiris** Rothsch. is very similar in its exterior to *aurola*, but different in the genital organs; antennal dents somewhat longer, legs and metathorax less white; ground-colour at least in the disc above deep chestnut red, the white postmedian line extends from the costal margin in an almost straight line to $\frac{2}{3}$ of the inner margin and is strongly undulate, its black interior border broad, basally faded, the blackish-brown line outside of it less densely scaled white than in *aurola*, behind the black subapical spot there are 2 black spots, not a dark red crescent; on the hindwing all the submarginal spots are black, only the uppermost feebly tinted red. From the dry season, South-Eastern Peru, at an altitude of 6000 m.

hesperus. **R. hesperus** L. (103 a). Dr. JORDAN writes me about this species: "LINNÉ's *hesperus* has nearly always been wrongly identified. LINNÉ quotes MERIAN's plate 52 under "*atlas*" and plate 65 under "*hesperus*"; he says that *hesperus* is more yellowish than *atlas* and that the larva is smooth, i. e. he has probably made his description according to MERIAN's plate. We have this light *hesperus*, which is very similar to *betis*, from French Guiana and the Amazons, and the grown-up larva has in fact no tubercles. PLOETZ' figures as "*procyon*" belong to this place; it is quite wrong to identify *hesperus* as a South-Eastern Brazilian insect; the typical locality for LINNÉ's types is Surinam (from Dutch collections), whilst nothing at all came from South-Eastern Brazil at that time." *Hesperus* is smaller on an average than *aurola*, lighter yellowish brown, the prothorax white, the metathorax not white; the antemedian line forms very characteristic round distal convexities in the cell and between it and the inner margin; the hyaline spots are relatively small, all the 3 sides in the ♂ slightly concave, the distal point just interrupts yet the black inner border of the postmedian line which is rather uniformly undulated, forming inward bows, on the veins distal points; the greyish pink notched band behind it is generally not very prominent and narrower than in *aurola*, the notches thereby somewhat shorter; behind the black subapical spot there are 2 small black spots more or less mixed with red. Panama to Guiana, Amazons, and Eastern Colombia. From Western Colombia (Bella Vista) originates (e Coll. NIEPELT) a most magnificent form, probably the most variegated of all the *Rothschildia*-forms: — **poecilator** *poecilator.* f. n. (134 a); median area Pompeian red, submarginal area orange-red, the lilac-white notched band before it distally very brightly bordered with dark brown; hyaline spots larger than in *hesperus*, their sides hardly concave, the white of the postmedian line has almost vanished owing to its broad orange distal border and the likewise broad black inner border; the large light subapical area is bluish-white, distally almost light blue, behind the black triangular subapical spot there are crimson spots; the flat black submarginal lunae are inside filled with olive yellow, the marginal area behind it is loamy brown, crossed by orange-red, subapically black veins. On the hindwing the 6 uppermost submarginal spots are crimson. At once discernible from the somewhat similar *chiris* by the entirely white collar.

betis. **R. betis** Wkr. (102 e) is of a still lighter orange yellow ground-colour, the antemedian line not convex, the apex of the forewing more produced, the postmedian line therefore more oblique, much less notched, between the costal margin and hyaline spot hardly notched, the white portion broad, the orange distal border narrow;

the greyish pink subterminal band is but very little prominent and does not extend so far to the costal margin; the reddish crescent behind the black subapical spot almost linear, the white subapical line above it notched, the submarginal crescentiform bows reddish or loamy brown. Brazil. In the Berlin Museum e Coll. MAASSEN by the manuscript name of: — **imitator** f. n. a large form very similar to *hesperus* with a less produced apex *imitator*. of the forewing, smaller hyaline spots and a somewhat more notched postmedian line, from Cayenne. Larva black, on each ring with 2 narrow red belts, without any tubercles.

R. morana Schs. (102 b) is somewhat like *betis*, of a more cinnamon reddish colour, the collar white *morana*. like the anal end; transverse lines broad white, antemedian line broader rounded, veins 2 and 3 broad white; hyaline spots very large, with obtuse points, on the forewing triangular, the lower sides at most very slightly concave, on the hindwing only the side towards the costal margin straight, the two others forming a single demi-bow; the postmedian line is strongly notched, the subterminal area, especially the inconspicuous feebly notched pinkish-grey band narrow; submarginal bows fine, brown, between the veins receding to the subterminal area, on the veins only as far as the centre of the olive brownish marginal area, in its deepest concavity bordered with white. On the hindwing the uppermost submarginal spots are red, the others deep black, the anal spot is the largest. Guatemala and Mexico (Misantla).

R. lebeau Guér. (= *lebeaui* auct., *bolivar* M. & W.) (102 a). Basal and subterminal areas red-brown, *lebeau*. median area darker, more or less tinted olive, costal margin dusted with white, transverse lines very broad white, antemedian line in its upper and lower portions slightly convex, at the lower cell-edge it forms but one point distally; hyaline spots especially in the ♀ very large, the distal point projects far beyond the postmedian line which is slightly undulate in its upper portion, towards the margin concave, in its lower portion particularly between 2 and 3 more notched; the greyish-pink subterminal band only extends to the centre between veins 3 and 4, above it only marked by darker brown dusting; submarginal line similar to *morana*, but darker blackish-brown. On the hindwing the pinkish-grey subterminal band hardly extends beyond vein 3 and, at the anal angle, it mostly leaves free a red-brown spot of the ground-colour. In the ♀ the hyaline spots are pear-shaped, oval; the submarginal lunular line is sometimes inwardly filled with black spots also on the forewing as on the hindwing: — **catenigera** ab. n.; type: 1 ♀ in Coll. DRAUDT. Mexico to Venezuela and *catenigera*. Colombia. At once separable from the very similar *orizaba* by the entirely white collar. WALKER'S *speculifer* var. 3. probably belongs hereto since the patria is stated to be Mexico. The larva is yellowish green or of a pure yellow with black torn transverse bands and red tubercles between. — **aroma** Schs. (101 e) is probably also *aroma*. a form of *lebeau*; in the ♂ the forewing is more falcate, the colouring more variegated, lighter and brighter reddish-brown; hyaline spots triangular, extending to the postmedian line, the transverse lines broad white; the pinkish-grey subterminal band extends up to beyond vein 5. In the ♀ the hyaline spots are especially large, oval, on the forewing pear-shaped. Honduras.

R. arethusa Wkr. (= *speculum* M. & W.) (102 c) resembles *lebeau*, the ground-colour is lighter yellowish *arethusa*. brown, the median area darker, narrower, the hyaline spots narrower, the hyaline spots narrower, too; the black subapical spot is pointedly triangular, the two black spots on the outside of it powdered with yellowish grey; postmedian line less undulate, in its upper and lower portions it forms one marginally concave bow each. Hindwing relatively short and rounded. Brazil, Paraguay, and Argentina. — In **rhodina** Jord. the postmedian *rhodina*. line is still deeper indented between the costal margin and the hyaline spot, the white and brown sealing behind it is more extensive, the hindwing slightly concave between the apex and vein 4, in the ♀ only feebly roundish. Amazons (Obidos). Larva black with yellowish green belts across the centre of each ring, and narrower similar segmental indentations; it pupates in an oblong cocoon forming a thick pupa hued with blue.

R. aricia Wkr. (= *arethusa* M. & W.) (102 c) is distinguished by the broadly rounded falcate apex *aricia*. of the forewing. Abdomen in its anal half above more or less white; ground-colour reddish-brown, often with a somewhat greenish tint, otherwise marked like *arethusa*; on the triangular hyaline spot of the forewing the lower slightly convex side is the longest, the proximal point touches the antemedian line; subterminal area, especially the pinkish-grey band is narrow, the latter distinctly darker blackish-brown, and widening towards the costal margin; the black subapical spot is not so pointedly triangular, the accompanying spots forming a yellowish-grey crescent. The hyaline spot on the hindwing is especially large. Colombia, Brazil. — **xanthina** *xanthina*. Roths. has more extensive white on the abdomen, the wings much more suffused with yellow, the submarginal area between veins 1 and 4 almost purely yellow or at least with 3 large orange spots. South-Eastern Peru.

R. orizaba Westw. (102 a) is of a most variable ground-colour, but invariably discernible from its allies *orizaba*. by the brown collar being only in front and behind narrowly white-edged as in the *aurola*-forms; hyaline spots longer triangular than in *lebeau*, postmedian line more notched, the greyish-pink notched band more distinct, extending farther upwards and mostly outside bordered by a darker colour; the ground-colour varies extraordinarily even at the same habitats, the median area is mostly olive brown, the basal and marginal areas more chestnut brown. Chiefly distributed in Mexico and extending in the north as far as Arizona. At the same

- ochracea*. habitats, in Mexico, there also occur ochreous specimens: — **ochracea** *f. n.* In Mexico another very conspicuous *prionidia*. form is found: — **prionidia** *f. n.* (134 a) of less than half the size, with a more falcate apex of the wing, light olive brownish ground-colour, the hyaline spots being proximally much deeper concave, distally extending far beyond the postmedian line, the very narrow light pink subterminal band almost reaching to the costal margin. I cannot decide whether it is a special condition-form; perhaps it is only a stunted form. Several specimens originate from the capital of Mexico, taken in June and August, without any transition-forms to *triloba*. the normal form. — In **triloba** *Rothsch.*, described from Costa Rica, the hyaline spots of both wings are proximally deeply indented, the lower side is twice as long as the upper, also on the hindwing, the point projects beyond the postmedian line. — **meridana** *Rothsch.* resembles the following form, but beneath the abdomen is less white; the hyaline spot of the forewing is proximally $\frac{1}{3}$ longer than costally, often concave; the hyaline spot of the hindwing is proximally shorter than costally, here just as long or longer than distally. Merida *bogotana*. (Venezuela). — **bogotana** *Rothsch.* is in the male brighter reddish-yellow, the abdomen beneath all white, the triangular hyaline spot on the forewing with straight sides, proximally and distally equally long, costally only half as long, touching the black postmedian line as on the hindwing and far remote from the anterior transverse line; the pinkish-grey band behind it is less broad than in *cauca*. The hyaline spot on the hindwing is distally rounded, the straight proximal side longer than the costal one; submarginal spots all equally large; the upper *cauca*. ones reddish. Colombia (Bogota). — **cauca** *Rothsch.*, from the Cauca Valley, is darker chocolate brown, with small hyaline spots, those on the forewing proximally straight, far remote from the anterior transverse line, and neither reaching the posterior line which is not so strongly dentate as in the nomenclatural type, between 2 and 3 not so deeply indented, finer, and more remote from the margin; the pinkish-grey band behind it is broader, but not so prominent as in *orizaba*; the subapical crescent is filled with red, the white line before it straight. On the hyaline spot of the hindwing the anterior and posterior sides are equally long, the proximal side rounded and short; the upper submarginal spots are very large, reddish. Beneath the costal margin of the *equatorialis*. forewing is not dusted with grey. — **equatorialis** *Rothsch.* is in the male bright tan-coloured brown, the ♀ ochreous, in the ♂ the subterminal area is also ochreous, in the disc reddish blackish-brown, dusted with white; postmedian line strongly dentate, the pinkish-grey band behind it broader than in Mexican specimens, the white dusting less dense; the subapical crescent is filled with red, the white line before it straight; hyaline spot proximally rounded, rarely straight, on the hindwing small, proximally very round, submarginal line better *peruviana*. marked than in the Mexicans. From Western Ecuador. — **peruviana** *Rothsch.* has a still more dentate postmedian line and a larger hyaline spot which is basally incurved or straight. Beneath all the submarginal spots of the hindwing are red. Carabaya (South-Eastern Peru). In the larva all the tubercles are equally large, conical; green, with a yellow sublateral stripe, anal plate and prolegs also green, edged with black; it lives on foliage trees such as cherries, ash-trees etc. The natives are reported to wear a necklet on which cocoons are threaded in order to prevent the whiskers from growing.
- prionia*. **R. prionia** *Rothsch.* (103 b) is allied to *zorulla*, but different in the genital organs; postmedian line in both wings strongly dentate, the white portion and its red distal border broad; the pinkish grey band distally to it is extended towards the costa as far as the apical spot which is brighter pink; the costal angle of the hyaline spot on the forewing is rounded, the proximal edge oblique; the hyaline spot on the hindwing is large, more than twice as long as broad, the basal end in front obliquely cut off, behind rounded; the pinkish-grey band is narrow, dentate, the posterior submarginal spots small, only the last being large. The species also resembles *lebeau*, but the postmedian line is more dentate, both the wings narrower, the hyaline spot on the hindwing much longer, the pinkish-grey band more dentate. North-Eastern Brazil, Venezuela.
- zorulla*. **R. zorulla** *Westw.* (= *splendida* *Clem.*, *cinctus* *Tepp.*) (101 c) is relatively small and slim, in the median area dark olive brown, the antemedian line between veins 1 and 2 mostly with a very distinct convexity towards the margin; posterior transverse line very strongly dentate, the white and red portions broad, the pinkish-grey band narrow, extending to veins 4 or 5; the hyaline spot of the hindwing is proximally either concave, straight or even convex, the anal submarginal spot mostly very large. This is the chiefly Eastern Mexican form which, however, was also found in Arizona. In Western Mexico (Guerrero, Colima) light cinnamon-reddish *guerreronis*. specimens predominate: — **guerreronis** *f. n.* (134 e); here the white portion of the postmedian line is mostly *inca*. extraordinarily broad, with larger hyaline spots. — **inca** *Rothsch.* shows the pinkish-grey subterminal band extended farther anteriorly, on the forewing more deeply dentate, on the hindwing posteriorly much less extensive than in the nomenclatural type, more sharply outlined, distinctly dentate; postmedian line finer, also its reddish-yellow distal border, especially towards the costal margin; posterior submarginal spots on the *zorulloides*. hindwing larger than in *zorulla*. From South-Eastern Peru. — **zorulloides** *Dogn.* exactly resembles *zorulla*, the ground-colour is just as olive brown: distinguished by the straight postmedian line being only moderately wavy and not so strongly and uniformly notched as *zorulla*; the white line bordering distally on the pink apical spot, is likewise straight. From Ecuador (Loja). The larva shows before its last moult yellow, at last red tubercles, the adult larva is quite smooth, green, with lateral blue and white oblique stripes, it lives on oaks, cherries, ailanthus etc., pupating in a cocoon similar to that of *orizaba*, though smaller and more regular.
- amoena*. **R. amoena** *Jord.* is similar to *zorulloides* and *maurus*, with shorter and broader wings, postmedian line somewhat less strongly dentate than in *maurus*, in front and behind curved somewhat more basad; the

subterminal band behind the white postmedian line is grey, only a narrow reddish line between both; the white subapical streak is shorter than in the allies; median branches in the central area yellowish reddish; hyaline spots triangular, all the 3 sides concave, the black edge distinct: on the hindwing the median area is broader than the distal area. Western Peru.

R. maurus *Burm.* (101 b) is distinguished by the brownish black ground-colour and by the quite straight *maurus*. and strongly and regularly notched postmedian line running as in *zorulla*; hyaline spots on forewing distinctly triangular, relatively small, almost as in *hesperus*, and on both wings remote from the postmedian line; on the hindwing the hyaline spots are more oval; the space behind the postmedian line is extensively strewn with grey, the light grey apical spot of the forewing relatively small, the white line distally bordering on it is followed by a large black triangular spot. Tucuman (Argentina). — **lutea** *Rothsch.* has a more loamy ground-colour, the *lutea*. postmedian line is less strongly dentate, on the forewing above the hyaline spot hardly dentate at all and basally incurved; the grey subterminal strewing is considerably more extensive, and distally produced on the veins; the hyaline spot extends with its point into the postmedian line, proximally in front incurved, below it convex; hindwing with especially large oval hyaline spots the black edge of which is more distinct than in *maurus*, the distal margin of the white line shows but very little pink; by the yellow tint the form also recalls *arethusa*. Paraguay, smaller and darker also from Rio de Janeiro.

R. maurusius (*i. l.*) *sp. n.* (101 c) has been known by this name since a number of years, but evidently *maurusius*. never described; smaller than *maurus*, in the ♂ the apex of the forewing is more produced, well distinguished by the subterminal area being strewn with bluish greyish-white as far as the apex and the marginal area, so that the large light triangular subapical spot is entirely absent, with transverse lines similar to those in *maurus*, but still more notched, the white portion just as broad as the flesh-coloured portion behind it: hyaline spots much larger; more rounded, reaching the postmedian line on the forewing; the triangular black subapical spot sharply pointed as in *arethusa*. Peru, Argentina. Perhaps *lichtenba* from Mexico is the northernmost representative.

R. lichtenba *Dyar* (102 b) is one of the smallest species looking like a very light drab *zorulla*, but the *lichtenba*. hyaline spots are oval, rounded, the subterminal band is strewn with light bluish-grey and extends to the costal margin, whereby it recalls *maurusius*; the black subapical spot is pointedly triangular as in *arethusa* and *maurusius*; above it there are 2 red crescents behind the strongly undulately dentate broad white subapical line. Western Mexico (Guerrero, Colima, Oaxaca). — **micrinus** *Maass. i. l.* (134 c) is a ♂ from Ecuador, in the *micrinus*. Berlin Museum; I take it to be a local form of *lichtenba*; ground-colour somewhat darker olive brown, hyaline spot triangular, the lower side being the longest, on the hindwing pear-shaped with a distal point; the white postmedian band is much narrower and less notched, particularly on the forewing in the costal portion.

R. tucumani *Dogn.* (= *vibidia Drc.*, *steinbachi Rothsch.*) (102 b) is the smallest species and quite different; *tucumani*. ground-colour olive yellowish grey, the anterior transverse line below the cell very round, the posterior one regularly flatly dentate, subterminal area very narrow; between veins 6 and 7 a very large round black spot, above it a smaller one and below it a pointed triangle; hyaline spot of forewing proximally very deeply concave, on the hindwing almost straight. From Argentina.

R. condor *Stgr.* (= *stuarti Rothsch.*) (101 b) is a very peculiar form connecting *tucumani* with *Eupackardia condor. calleta*. Ground-colour blackish-grey; hyaline spot of forewing very narrow and elongate with a continuation to the costal margin; submarginal markings very similar as in *calleta*. On the hindwing the hyaline spot is distally pointedly prolonged. We figure STAUDINGER's type from the Berlin Museum. High Andes of Peru and Bolivia.

R. jacobaeae *Wkr.* (= *affinis Fldr.*) (103 a) introduces quite a different group of species. Ground-colour *jacobaeae*. chestnut-red, at the costal margin broadly dusted with greyish-white; hyaline spot almost pentagonal owing to the long lower side resting on the median for some distance and the costal side exhibiting basally a small appendage which is straightly cut off above; hyaline spot of hindwing exceedingly long; postmedian line flatly undulate-dentate, in the costal portion on the forewing inwardly very convex, the 2 subapical black spots similar as in *tucumani*, but more triangular. Submarginal spots very high, in the shape of a horizontal X, or butterfly-shaped. Larva exactly like that of *splendidus*, $\frac{1}{3}$ larger, green, with 2 light yellow oblique bands and a red, below yellow-edged anal spot. Southern Brazil, Argentina.

R. erycina *Shaw.* (= *hesperus Cr.*, *satyrus Fldr.*, *amazonia Pack.*) (103 a) is similar, of a most variable *erycina*. ground-colour, postmedian line more notched, in the costal portion on the forewing still deeper concave; from the apex of the hyaline spot 2 or 3 black stripes extend to the submarginal line; the small subapical spots are reddish, outside pointedly triangular. The nomenclatural form from Southern Brazil to Argentina. The northernmost form is: — **nigrescens** *Rothsch.* from Costa Rica; here the median area in both wings is heavily *nigrescens*. suffused with black, the pink subterminal area narrower than the space from here to the margin, and it extends upward to the apex of the hyaline spot, outside of it there is a brownish-black band, between the latter and the margin on the forewing there are van Dyke-brown spots, behind them a sand-coloured grey band, on the hindwing a series of large black double spots, distally to them a series of intense black streaks; hyaline spots

- martha*. smaller than in *erycina*. — **martha** *Rothsch.* is similar to *nigrescens*, but less blackened in the median area, the pink area in the hindwing broader than the marginal area; the brown band outside of it narrower than in *nigrescens*, and lighter brown. The black submarginal spots on the hindwing are smaller, the distal streaks thinner; hyaline spots still smaller than in *nigrescens*. Sa. Martha. — **vinacea** *Rothsch.* is in the median area of a brighter wine-colour than *e. erycina*, the black borders of the transverse lines are broader, the hyaline spots larger, on the forewing the spot at the apex of the hyaline spot black, the red subterminal area is narrower, outside bordered by an undulate pure white or yellowish-white line; the blackish-brown line distally to it narrower than in the other forms; the spots on the hindwing distally to the pink area are deeper brown than in *erycina*, the submarginal spots blacker. South-East Peru. — **luciana** *Rothsch.* is a West-Indian insular form, hitherto ascertained in Sa. Lucia; ground-colour dingy tan-coloured, in the median area only slightly tinted red, the white transverse lines broad, the posterior line in the costal portion on the forewing not dentate, the ochreous border of this line broad; the subterminal area at the apex of the hyaline spot but little darker than the apical part of the costal-marginal area, the grey subterminal band distally bordered with reddish-brown; the white line from the apex to the hyaline spot behind more remote from the blackish postmedian line than in the other subspecies; the loamy grey submarginal band is subapically lobately expanded inwards. On the hindwing the black submarginal spots are small. — According to the kind information by Dr. JORDAN, the type of *satyrus* is a very dark specimen of *erycina* being painted over except some small places, the under surface dull blackish-brown, darker than in all the other specimens though not painted over.
- hopfferi*. **R. hopfferi** *Fldr.* (= *pegasus* *Bsdv. i. l.*) (103 b) is more yellowish-brown than *erycina*, the apex of the forewing especially in the ♂ more prolonged, the hyaline spots of the forewing longer, triangular; the lower side is the longest, on the hindwing a very long rhombus with entirely parallel sides. Brazil (Bahia, Sa. Catharina). — **rhombifer** *Burm.* is nothing but a somewhat browner form with broader wings and a less produced apex of the forewing, from Argentina and Paraguay.
- splendidus*. **R. splendidus** *Beauv.* (= *hesperus* *Cr.*, *belus* *M. & W.*) (103 b) is smaller than the preceding species, of a dark red-brown ground-colour, the apex of the hyaline spot on the forewing projects far beyond the postmedian line, the basal side of it prolonged in an appendage to the costal margin, the subterminal area almost as dark as the median area, especially also the large subapical area. Distributed from Mexico to Southern Brazil. — *mexicana*. In the much smaller Mexican form: — **mexicana** *f. n.* both the wings are shorter, the hindwings rounder; the hyaline spots are smaller, the large subapical area lighter, the white postmedian line outside bordered by a pinkish-red line, the subterminal area behind it broader than in the nomenclatural form, lighter pinkish-grey, parted by a whitish line; the marginal area is apically more yellow, in the lower half parted by a distinct darker submarginal undulate line. Thorax and abdomen lighter claret-coloured. Huatusco. Type in Coll. DRAUDT. Larva green with white oblique stripes traversing 2 rings from in front above to behind below, and red anal feet. It lives on orange trees.
- zacateca*. **R. zacateca** *Westw.* (103 c) is not to be confounded with any other species by the uncommonly large oval hyaline spots; ground-colour black, brightened by dark cerise; the transparent postmedian line is very near to the margin, the small black diaphanous subapical spot surrounded by bright carmine. The ♀ is much redder, with a broader subterminal area which is strewn with bluish-grey. Colombia (Bogota).

3. Genus: **Eupackardia** *Ckll.*

This genus was established for a single species, the exterior of which is already more similar to the genus *Callosamia*,^f but also has some resemblance to *Rothschildia*, and is allied to *R. condor*, as we mentioned at that place. The shape of the wings is generally somewhat broader and rounder, the discal spot no more transparent, but scaled, and exactly shaped as in the *Samia*-species. In the neuration there is no essential difference to be found. Palpi somewhat longer.

- callela*. **E. callela** *Westw.* (= *polymmata* *Tepp.*) (101 b). Blackish grey, forewing with 2 white transverse bands, the anterior one narrow and angular, the posterior one broad, flatly S-shaped, behind it a series of blue-pupilled black small eyespots, the uppermost of which is larger and outside bordered by deep carmine. Hindwing only with the distal band. Discal spot tricuspidate arrow-shaped, or more or less reduced, it is either absent on the hindwing = **semicaeca** *Ckll.*, or on both wings = **caeca** *f. n.*, as in a ♀ specimen of my own collection. *semicaeca*. Guatemala and Mexico, from where it penetrates to North America (Arizona). The larva has the same shape as *Phil. cynthia*, but the tubercles are much thicker and larger. Green, the tubercles at the thickened base red, above it turquoise blue, the small short spines black. Legs and anal shield yellow, the yellow prolegs basally black, it lives on cherry.

4. Genus: **Callosamia** *Pack.*

Very closely allied to the preceding genus, distinguished by the very distinct sexual dimorphism. They are somewhat smaller species, the scheme of marking recalling that of *E. callela*, but the postdiscal band is

undulate-dentate, irregular. In the neuration hardly any difference; palpi somewhat shorter; on the ♀ antennal joints the anterior two pectinations are shorter than the posterior two. Larvae not essentially different from the general type, but distinguished from those of *Philosamia* by only the 2nd, 3rd, and 11th rings bearing fleshy thorns, the other rings only punctiform tubercles. The cocoon is suspended on a stalk and mostly wrapped up in leaves.

Type: *C. promethea* Dru.

C. promethea Dru. (129 b). The ♂ is black with a but very feebly traceable postdiscal line, in the yellowish-grey margin with a black undulate line which is transformed into small spots on the hindwing; apex of forewing above the black eyespot dusted with dark red, with a short white notched line; no discal spots. The larger ♀ is more purple brown, both the lines of the forewing distinct, like the discal spots, the spot on the forewing is mostly very small or obsolete. ♀-specimens without any discal spot are named: — **caeca** Ckll. Larva bluish-green, the fleshy thorns coralline. It chiefly lives on Laurus, Liriodendron, Liquidambar, and cherry. The silk of the cocoon cannot be used. Predominantly occurring in the Atlantic States, from South Canada to Florida, to the west through the Mississippi Valley as far as the eastern frontier of the great prairies. The ♀ of *promethea* has been hybridized with *cinthia*-♂; the product has the colour of *cinthia*, with the discal spots and shape of *promethea*-♀.

C. angulifera Wkr. (129 c) is very similar, the ♂ browner, with both the transverse lines, the posterior one of which is distally dusted with whitish in a variably broad extent. The ♀ is much more variegated, ground-colour from cerise to orange-yellow, with much larger discal spots, those on the ♂ hindwing mostly obsolete. — **carolina** Jones is smaller and lighter and has yellow discal spots and transverse bands, the area outside of it dusted with golden brown. Beneath the transverse lines are purple red instead of black. Southern Carolina. — **securifera** M. & W. (129 c) the types of which we can figure is perhaps only an especially light form of *carolina*, in the ♂ the ground-colour is much lighter brown, in the ♀ quite light yellow. The statement of the patria: Central America is surely wrong. Larva similar to that of *promethea*, but with fine black belt-markings before the last moult; it chiefly lives on the tulip-tree; the food-plant of *carolina* is stated to be Magnolia glauca.

5. Genus: **Samia** Hb.

Extraordinarily similar to the preceding genus and externally characterized by larger species with broad, rounded wings with non-diaphanous discal spots and without the distinct sexual dimorphism of *Callosamia*. The ♀ antennae are still somewhat shorter combed than in the latter, the legs are covered with very dense woolly hair. Larvae on the 2nd to 4th rings with one pair each of more ball-shaped shortly spined fleshy cones and a single one on the 11th ring, whilst the other rings bear longer and thinner small fleshy thorns exhibiting a few bristly hairs on the tips. The cocoon is not suspended, but fastened on the twig longitudinally. — The following hybridizations have hitherto been ascertained: *cecropia* ♂ + *gloveri* ♀, *cecropia* ♂ + *rubra* ♀, *columbia* ♂ + *cecropia* ♀ and reversely, moreover *promethea* + *gloveri*.

Type: *S. cecropia* L.

S. cecropia L. (101 a) is one of the best known moths. Rather invariable, olive brown with 2 transverse bands which are bordered with whitish on the averted sides, and with crescentiform discal spots, the one of the forewing being more or less tinted red. Marginal area yellowish-grey with a large black spot inwardly light blue, then again black-ringed, between 6 and 7; subterminal area more or less suffused with red. Larva light green, cones and pectoral feet yellow, the fleshy thorns on the 2nd and 3rd rings orange red or coralline. It lives on various trees and shrubs such as roses, willows, maple, lilacs etc. Distributed over the whole Atlantic coast of North America to the west as far as the great prairies. — An artificial form bred by an experiment of temperature is named: — **macula** Reiff which shows a submarginal row of black spots also on the forewing, as on the hindwing. *cecropia* can be hybridized with all the 3 other species of *Samia*.

S. gloveri Stkr. (101 a) is distinguished by a more cerise or Pompeyan red interior half of the wings, the whole subterminal area being yellowish-grey, strewn with dark. — **reducta** Neum. is a smaller stunted form from the high mountains of Colorado. The larva is very similar to that of *gloveri* and likewise polyphagan. Rocky Mountains from Alberta and Assiniboia to the south as far as Arizona. *gloveri* can easily be hybridized with *cecropia* and also with *columbia*, the product is also found in nature.

S. columbia Sm. (101 a) is smaller on an average, of a duller colouring, not so bright red as the preceding species, especially the postdiscal line is outside not at all shaded with red. Larva on larches. From the Northern Atlantic States. — **nokomis** Brodie is the form from Manitoba, of a brighter colouring, with a larger white spot on the hindwing. — **wenonah** Brody, from Pelly, North-Western Territory, is smaller and still brighter, the colours more distinctly contrasted; the only extremely northern specimen known is presumably only an intensely marked *nokomis*.

rubra. **S. rubra** Behr (= *curyalus* Bsd., *californica* Grt., *ceanothi* Behr) (129 c) is easily separated by the quite red ground-colour. — *parvima-* **parvima-** **macula** Grt. is distinguished by the reduction of the discal spots. — **kasloensis** Ckll. is above darker purple brown, beneath much blacker and less red. From British Columbia. — **cedrosensis** Ckll., *kasloensis.* from Mexico (Cedros I.), is broadly and diffusely blackened at the distal margin in both wings above, with *cedrosensis.* hardly any submarginal markings; ocellus of forewing small; beneath intensely blackened. — In aberrative specimens the ocelli may be entirely absent as in *E. calleta*. Larva green with blue or yellow knobbed tubercles with black thorns. It lives on *Ceanothus thyrsiflorus*, but also on cherry and apple. *Rubra* can be hybridized with *cecropia*, the product being occasionally also found in nature.

II. Group.

Cell of forewing closed (Saturniinae).

1. Division. Vein 1 b of hindwing absent (Saturniinae s. str.).

1. Genus: **Sagana** Wkr.

Shape somewhat like that of the palaearctic *Rhodinia*, of medium size, the ♂ with a roundedly produced apex of the forewing, on both wings with crescentiform hyaline spots enclosing the likewise curved cross-vein. On the forewing 5 comes from the upper cell-angle, 6 close before it, 7 and 8 from the centre of the upper cell-margin, 9 and 10 being quite absent. Cell of hindwing very long, 5 from the upper angle, 6 a little before it; 7 terminates into the apex. Proboscis rather well developed, palpi rudimentary. Antennae of ♂ bipectinate, in the ♀ shortly pectinate.

Type: *S. sapatoza* Westw.

sapatoza. **S. sapatoza** Westw. (103 c). Wings on the greyish brown ground densely strewn with greenish yellow, the most densely on the averted sides of the two transverse stripes, the distal one of which is undulate; submarginal area mixed with a darker red-brown, at the apex of either wing a small black, distally white-pupilled spot. Colombia. It has recently also been bred, but apparently nothing has yet been published about the early stages.

2. Genus: **Saturniodes** Rothsch.

Very closely allied to *Sagana* and also *Copaxa*, with longer antennal combs, the anterior tibia with a short or absent spine. Cross-vein straight, in the centre of the mostly round hyaline spot. The subcostal vein of the hindwing terminates in the distal margin. A few species from the High Andes.

Type: *S. medea* Maass.

medea. **S. medea** Maass. (104 a) is a variable large beautiful species; blackish-grey, strewn with yellow, with 2 undulate-dentate transverse stripes which are bordered with white on the averted sides, the exterior stripe being double. Eyespot of forewing with a large hyaline centre, distally finely surrounded with yellow. In the nomenclatural type the submarginal line of the forewing is narrow, the apical spot above and beneath small. Under surface blackish brown, both wings with a narrow white submarginal line; below the apical spot of the *carina.* forewing there is a narrow, white crescent bordered with red. Ecuador. — **carina** Rothsch. The white submarginal band of the forewing is 5 mm broad; beneath strongly mixed with yellow, the grey ground almost entirely suppressed; the black apical spot of the forewing is smaller than the ocellus of the hindwing, the submarginal bow below it is red, not larger than the black following bow. Carabaya (Southern Peru), from an altitude of *charila.* 9000—9500 ft. — **charila** Rothsch. Like *carina*, the white submarginal band broader and also beneath very distinct. Beneath preferably greyish-white, both wings with a blackish-brown band mixed with yellow distally to the eyespot of the forewing and straight through the eyespot of the hindwing; the submarginal black and *miles.* red is more extensive than in *carina*. Marcapata (South-Eastern Peru), according to 1 ♂. — In **miles** Rothsch. the white submarginal line is narrower, the black apical spot of the forewing larger, on the under surface a large red spot behind it. The white submarginal line of the hindwing is distinct, on the forewing only behind distinct; ground-colour whitish-grey. Abdomen laterally with a black, white-edged line. From Western Peru. All these forms are extremely rare hitherto, our figure has been made according to a magnificent ♂ of the Berlin Museum.

orios. **S. orios** Dyar (104 a). According to the photo of the type which was most kindly put at our disposal, it seems to be very similar to the form *carina*, unless it be *carina* itself. Apex of forewing apparently somewhat more produced, apex of hindwing more angular, its distal margin straighter and the anal angle more produced; median area on both wings narrower, subterminal line broad, on the hindwing the antemedian line touches the eyespot. Beneath grey, only towards the margin strewn with yellow, with a black straight median band across both wings, the white submarginal line absent in both wings. Cuzco, Peru, 11 500 ft.

ockendeni. **S. ockendeni** Drc. is likewise similar; antennae and abdomen quite black. Forewing dark brown, strewn with yellowish; antemedian line yellowish white, subterminal line light brown, not white, more obliquely extending from near the apex to the centre of the inner margin, distal margin fawn. Antemedian line of hindwing quite black, without any white, only bordered by few yellowish scales, not reaching the costal margin. Under

surface dark red-brown, strewn with black, the transverse lines broader than above and quite black, without any white; at the apex 2 red spots. 5 inches. South-Eastern Peru, Carabaya (7000 ft.).

S. muellerana Dyar, of which only a photo is before me, is undoubtedly also a *Saturniodes* though it was described as an *Agapema*. Antennae light yellow. Wings shaped as in *medea*. Of a soft greyish-brown colour, the antemedian line in both wings blackish, faded and broad, subterminal line double, undulate, the interior portion black and more distinct, the exterior one broader and distally strewn with white; at the apex a flesh-coloured spot enclosing an inwardly black, outwardly red spot; ocellus black with a straight white central line, with brown, red, and black rings, proximad between the red and black with a narrow white demiring. Hindwing in the costal-marginal area light yellowish, without an apical spot, ocellus similar as on forewing. Expanse of wings: 97 mm. Mexico City, only 3 specimens known hitherto. — **heringi** f. n. (104 b) probably belongs to it, but it has a quite sooty black ground-colour, the marking is otherwise the same except the transverse lines being more distinct, those on the hindwing much deeper and roundly sinuate, in *muellerana* inwardly forming acute angles on the veins, the costal-marginal portion here considerably broader light, almost greenish yellowish-white, extending to the eyespot; the shape of the wings appears to be somewhat higher and more slender. According to 1 ♂ from Panama. Type in the Berlin Museum.

S. copaxoides Dyar (104 b), likewise described as *Agapema*, also belongs hereto, a smaller species with blackish-brown wings, a reddish-white collar and costal margin of the forewing, marked as the preceding ones; antemedian line especially on forewing feeble, the little eyespot rosy-red, in a black ring with a white-hyaline central streak, of a somewhat oval shape; subterminal line only indistinctly double, on the hindwing more distinct. Marginal area behind it lighter, at the apex a white spot centred black and red. Western Mexico (Guerrero; Colima).

S. semioculata Fldr. (104 a), in my opinion, belongs quite near to *copaxoides* and cannot be a *Sagana*. Only known to me from FELDER's figure according to 1 ♀. Marking almost the same as in *copaxoides*, only the ground-colour somewhat more yellowish; eyespots oval, especially that on forewing very narrow. Stated from Venezuela.

3. Genus: **Copaxa** Wkr.

A large group of imposing, often sexually dimorphous species mostly with hyaline spots on the wings, the apex of the forewing being usually falcately pointed or rounded produced. Palpi very short, drooping. Forewing with a somewhat rounded cellular apex, 6 proceeds a little before the upper angle, 7 and 8 stalked from the centre of the anterior edge of the cell, 9 and 10 absent. Hindwing the same, 5 from the upper angle, 6 a little before it, 7 from the centre of the anterior edge of the cell, terminating far below the apex into the distal margin. Abdomen mostly short and relatively slim. The species often have a most variable colouring. There is still little known of the biology.

Type: *C. decrescens* Wkr.

C. decrescens Wkr. (130 a). Light greyish-brown with an olive tint or also more reddish-brown, especially in the cell, or with a light pink tint particularly behind the distal oblique line which runs straight from below the apex to the centre of the inner margin; the interior transverse line below the cell sharply broken inward; hyaline spot small, triangular, surrounded by yellow, in the ♀ larger. Hindwing with a straight, distally light-edged antemedian line, a feeble median shadow behind the small hyaline spot and an undulate-dentate postmedian line with sagittary thickenings on the veins; the space behind it feebly darkened in the shape of a band. Costa Rica, Panama, Colombia to Brazil, a common species. — **olivina** f. n. I call a very light olive greenish form with a lilac silvery grey brightening in the marginal area. — **purpurascens** f. n. (105 a) is a dark purple brown form dusted with lilac, with a whitish lilac pink brightening in the marginal area. — **rufinans** Schs. (105 b) are bright red-brown forms with a rusty yellow brightening in the cell and above it, whilst the surroundings of the apex of the cell is darkened greyish-brown as far as the oblique line. The last 3 forms with all their transitions from Mexico. The ♀♀ seem to occur chiefly in the form *purpurascens*, at least I have seen no others among the great number of specimens before me. — **troetschi** Drc. (= *marona* Schs.) comprises light reddish fawn forms, the transverse lines distally dusted with lilac pink, the cell and median shadow more rusty yellowish or reddish. The apex of the forewing is figured excessively long in the Biologia, but in fact it is longer than in Mexican specimens. The type from the Berlin Museum is lying before me. Panama to French Guiana. — **niepelti** f. n. I call a very variegated form from Western Colombia (Bellavista), type in the Coll. NIEPelt; ground-colour warm brownish olive, the cell before the antemedian line bright fox-coloured, behind it more feebly dusted so, the postmedian line on both wings outside bordered with light lilac pink, the hyaline spot, especially that on the hindwing, in a very broad and bright orange ring.

C. sophronia Schs. may be a form of *decrescens*; dark olive brown, collar and basal half of costal margin strewn with white, the small hyaline spots at first orange, distally finely surrounded with black, transverse lines darker, median and postmedian areas between 2 and 7, excepting the upper half of the cell, shaded darker; from the costal margin to vein 6 a darker postmedian shadow behind which the apical area is lighter; the fine postmedian interior notched line from the costal margin to the centre of the inner margin distinct, behind it

between 7 and the inner margin a 3rd brownish line; margin between 6 and the apex shaded darker, at the apex a small white spot strewn with black. Hindwing in the basal half darker, behind the dentate dark postmedian shadow a deeply dentate dark line with dark short vein-streaks, behind it brownish lunulae. Expanse of wings: 115 mm. Guatemala.

curvilinea. **C. curvilinea** Schs. may also be a form of the preceding species; monotonously dull brown, collar whitish, costal margin as far as beyond the centre yellowish-reddish grey; antemedian line feebly marked, the small hyaline spot as in *decrescens* finely surrounded with black and yellow; postmedian line outside between 6 and the inner margin narrowly bordered with lilac-whitish, the same feeble dusting at the distal margin. Hindwing with a straight antemedian line, the hyaline spot with a broader ochreous ring, behind it a brown shadow, then lilac whitish streaks and black vein-dots which are connected by a feeble darker undulate line; subterminal whitish vein-dots. Expanse of wings: 102 mm. Costa Rica.

denda. **C. denda** Drc. (105 b). Yellow, collar and first third of costal margin light lilac grey; base of cell and the space before the distal oblique line more or less extensively dusted with rusty reddish; the reddish-brown antemedian line similar as in *decrescens*; the oval hyaline spot finely bordered with black, then yellow and again black; before the blackish-grey oblique line an indistinct red-brown notched line, the marginal area also on the hindwing more or less hued with light lilac grey. The ♀ is more cinnamon reddish and more intensely marked. Mexico, Guatemala.

syntheratoides. **C. syntheratoides** Roths. (105 b) is similar to *denda*, but of a much purer yolk-colour and in the ♂ hardly marked at all, in the ♀ much more, similarly arranged as in *denda*, but the hyaline spots are much larger and quite round, parted by the cross-vein; behind the postmedian line in more distinctly marked specimens reddish-brown shading which exhibits two rounded projections between 2 and 4. Hindwing with small rusty brownish subterminal shadow-like spots. Legs rosy reddish. Panama.

anestios. **C. anestios** Weym. This species having been described from 1 ♂ without the patria being stated must look very much like *denda*, but it has no sharply pointed, but an obtusely rounded apex of the forewing. Golden yellow with a straight red-brown oblique stripe as in *denda*; the small oviform hyaline spot is bordered by a very fine brown ring, then a yellow one, and outside a red-brown one, proximad above it another punctiform hyaline spot; costal margin red-brown with white scales, from its base along the median vein, between 2 and 4 and through the distal half of the cell a distally widening red-brown longitudinal stripe as far as the postmedian line, another similar stripe from the centre of the costal margin across the veins 5 and 6; basal 2 notched red-brown transverse stripes; before the apex a small white costal-marginal triangle; marginal area as in *syntheratoides*-♀. Hindwing marked the same, before the margin with 2 red-brown notched lines, the exterior one broader and more indistinct. Expanse of wings: 115 mm.

cinerea. **C. cinerea** Roths. (122 a) is unicoloured ash-grey, without any transverse lines, only on the hindwing there are traces of an antemedian line; at the cell-ends of both wings small hyaline spots. Expanse of wings: 127 mm. Described from 1 ♀, habitat unknown.

expandens. **C. expandens** Wkr. (105 a). Wings broad, apex of forewing pointed; golden yellow, in the disc behind and above the cell dusted with blackish-brown, around the cell-end with 3, sometimes 4 small hyaline spots; antemedian line irregular, postmedian line fine, undulate-dentate, behind it a broad black straight nebulous stripe, distally between 2 and 4 projecting with 2 round convexities. Hindwing with a straight broad antemedian line, in the disc with 1 or 2 small hyaline spots; a rounded undulate-dentate postmedian line and a submarginal nebulous stripe which is more broken up in spots. Venezuela.

arpi. **C. arpi** Gschwandner is very similar, larger, the apex of the forewing obtusely rounded; ground-colour darker, ochreous, behind and especially above the cell dark brown irroration, enclosing 3 hyaline spots with black, yellow, and again black edges; the subterminal black nebulous stripe is distally concave, and widened between the veins 4 and 6, the notched line before it as in *expandens*; the subterminal darkening between 2 and 4 is very feeble. Hindwing similar as in *expandens*, the hyaline spot at the cell-end small, oval, surrounded by black, yellow and again black. Expanse of wings: 113 mm. Southern Brazil, Sa. Catharina.

trimacula. **C. trimacula** Roths. is very similar to *arpi*, much larger and at once discernible by the absent notched stripe before the postmedian oblique stripe. Forewing loamy brown, sometimes covered with light reddish, behind the cell with 3 round hyaline spots; $\frac{1}{3}$ from the base extends an indistinct zigzag line, from the apex to the centre of the inner margin a dark oblique line. Hindwing similar, but with only one hyaline spot, behind it there are a number of small round dark spots; an antemedian transverse line. Expanse of wings: 136 mm. Central America.

multifenestrata. **C. multifenestrata** H.-S. (130 a) is an extraordinarily variable species, in the typical form fawn-coloured greyish-brown, especially in the female sex, the two black transverse lines (the posterior one mostly only in its apical portion) notched, before the latter a second notched line of a more brownish colour; around the cell-apex 4 hyaline spots, the second from below being the largest and parted by the cross-vein; before and below the cell-end especially in the ♀ 2 small hyaline spots; posterior transverse line outside analwards wider darkened, between 2 and 4 with 2 more or less distinctly biapic projections. Hindwing the same with 3—6 hyaline spots in the disc. In the ♀ a principal subspecies with a beautiful yolk-coloured ground-colour occurs: —

flavescens f. n. (130 d); purely yellow ♂♂ matching it I have not seen. The yellow ♂♂ are mostly extensively *flavescens*. dusted with violettish grey or red-brown, especially subterminally and around the cell-apex. — **rufotincta** *rufotincta*. *Rothsch.* (130 e) is in the basal $\frac{2}{3}$ reddish orange, in the marginal third deep brown. Panama. — **rufa** f. n. are *rufa*. deep chestnut-red, — **olivina** f. n. dark olive brown specimens. Mexico-Panama, also from Western Colombia *olivina*. before me in the typical form (Coll. NIEPELT).

C. satellitia Wkr. (130 d), described from Brazil, in my opinion is by no means identical with *multifenestrata*, but a different species; typical *multifenestrata* I have not seen farther to the south than Panama and Western Colombia. From Brazil 2 ♀♀ are before me, which are very closely allied to the said species though constantly differentiated. Shape of wings somewhat narrower, distal margin more oblique, position and proportion of the hyaline spots to each other different; in *multifenestrata* the uppermost is relatively large, the following small, in *satellitia* the uppermost the smallest, the 3rd and largest is in the former species bipartite by the cross-vein, in *satellitia* besides divided into 3 parts by the fold, the spots on the hindwing being much rounder; the posterior transverse line on both wings hardly notched, broader, more faded and indistinct, outside more intensely strewn with whitish-grey.

C. simson Maass. (105 c) is the largest *Copaxa*, dark yellow or orange brownish, strewn with red-brown *simson*. especially in the median area excepting the inner-marginal portion, costal margin and collar intensely strewn with white, veins of median area blackened; transverse lines as in the other species, on the hindwing very deeply undulate-dentate; hyaline spots large, inside surrounded with grey, then yellow and outside finely with black; marginal area lighter. From Panama.

C. canella Wkr. (104 d ♀, 105 a ♂). Light brown with the usual 3 transverse lines, ocellus as in *simson*; *canella*. collar and costal margin intensely strewn with white. Brazil, a more common species. — **flavina** f. n. (105 c) *flavina*. are specimens with a golden yellow ground-colour, in which especially the upper half of the median area and the subterminal space behind the line are intensely strewn.

C. joinvillea Schs. (105 c) is very similar to *canella*, mostly somewhat smaller and darker, easily *joinvillea*. discernible by the longer and somewhat more narrowly produced, falcate apex of the forewing. — Whether — **vitellina** f. n. (105 c) is a yellow form of it or a distinct species I cannot tell according to the only specimen before *vitellina*. me. Apex of forewing not quite so far produced as in typical *joinvillea*, the colour is a pure golden yellow without strewing, the marking otherwise not different. Southern Brazil.

C. lavendera Westw. (= *chapata* Westw., *plenkeri* Fldr.) (104 d) is marked like the preceding species, *lavendera*. but sexually very dimorphous, the ♂ of a most variable colouring; light orange brown, red-brown, dark or olive brown, the distal oblique stripe mostly distally strewn with white, ocelli much larger and more variegated. The ♀ is yellow, in the median area strewn with black, behind the distal oblique line red-brown with black strewing, between 2 and 4 with 2 round projections; marginal area loamy brownish. Mexico.

C. mannana Dyar (120 a) may also belong to this genus. Forewing of ♂ with a falcate apex; brown, *mannana*. costal margin and collar grey; forewing with a small slit-shaped hyaline spot, the feeble transverse lines purple brownish, the interior line irregular, the exterior one feebly double. Hindwing from the costal margin to beyond the cell excepting the margin rosy red; discal ocellus large, black, inside with a light blue dusted crescent with a broad reddish-yellow ring and surrounded by black; the two transverse lines disappear in the pink costal-marginal area, the exterior line is undulate-dentate. The ♀ has more quadrangular wings with a straight distal margin, yellow, strewn with grey, collar and costal margin grey, the discal hyaline spot tiny, transverse lines broader and more distinct, marginal area excepting tornus hued with pink, with a small dark subcostal spot. outside dusted with pink and purple. Expanse of wings: ♂ 95, ♀ 100 mm. Mexico, Hidalgo, 9000 ft.

C. cydippe Dre. (103 d) has been described as *Attacus*; I know it only from the description and figure *cydippe*. in the Biologia and place it here only provisionally, because it neither fits to any other place. Apex of forewing very pointedly falcate; colour dark red-brown with transverse lines as in *lavendera*-♀; each wing exhibits a small narrow oval discal hyaline spot, and subterminal markings which are very near to the margin and composed of small outside rounded spots distally surrounded by light grey. Described from Orizaba (Mexico).

PACKARD, in Monograph etc., 1914. p. 164, mentions another *C. disjuncta* without any description, in which vein 9 of the forewing rises from 8 as a very short branch close before the apex; who is the author? I could not discover anything else about it.

4. Genus: **Agapema** Neum. & Dyar.

It represents the palaearctic genus *Eudia* Jord. (cf. Vol. II, p. 222) in America and, in fact, hardly differs anatomically. The antennae especially in the female slightly longer pectinate, likewise with a bare ventral stripe. Forewing with exactly the same neurulation, though I find 5 and 6 of forewing to be short-stalked in *homogena*, in *galbina* not so. The costal vein of the forewing terminates into the costal margin, the subcostal vein into the apex. Thus it appears hardly necessary to separate it from the genus *Eudia*.

Type: *A. galbina* Clem.

galbina. **A. galbina** Clem. (103 d). Rather scantily scaled, brownish grey with 2 broad not quite distinct transverse lines and very faint traces of a somewhat undulate subterminal line; eyespot from outside inwards: black, yellow, black with a hyaline central streak; in the apex a black spot distally bordered with white, then with red; distal margin bone-white, outside passing over into the grey ground-colour. Hindwing the same, but the basal area lighter. We figure an aberrative ♂ in which the median area is broadly interrupted by the widened white transverse stripes: — **interrupta** ab. nov. (103 d as *galbina*). Arizona and Northern Mexico. — **anona** *Ottolengui* *anona*. on the whole is a darker local race from Texas; especially the basal and median areas of the forewing are more blackish with more distinctly prominent white transverse bands and markings; the costal area of the hindwing is likewise darker scaled with a dark subbasal demi-band. The Mexican race (from Chihuahua) has been *dyari*. separated as — **dyari** Ckll. and is characterized by lighter hindwings. Larva on Grease wood, the young larva has been described to be black with long fawn-coloured hair.

homogena. **A. homogena** Dyar. (103 d) is larger, more densely dusted, with a darker ground-colour, the veins distinctly marked light yellowish ochreous, the inner transverse line yellow, pointedly produced distally on the median vein, the outer line almost straight, narrow, white; costal margin and the outermost border of the bone-white marginal area ochreous; ocellus as in *galbina*, but besides with a light blue crescent in the proximal half between yellow and black. Hindwing lighter, only with the distal transverse stripe. Mexico, also found in Arizona.

5. Genus: **Calosaturnia** Sm.

Anatomically hardly separable from *Agapema* or *Eudia*, at most somewhat smaller and more slender, the antennae a little shorter and somewhat shorter pectinated. In the neurulation no essential difference. Biologically different by the larvae the thorns of which produce a burning sensation. Only 1 species:

mendocino. **C. mendocino** Behrens (103 d). Forewing red-brown, only with the discal ocellus, without distinct transverse stripes. Hindwing orange with a broad black subterminal band and discal eyespot. Northern California. The eggs are deposited in numbers of 1—10 pieces on leaves of “Manzanita” (*Arctostaphylos tomentosa*). Larva green or reddish-brown, with severely burning thorns.

6. Genus: **Polythysana** Wkr.

Very similarly structured as *Automeris*, but palpi short, apex of forewing somewhat produced though rounded. On the forewing 3 rises somewhat nearer to 4, 6 on a short stalk with 7 and 8. On the hindwing the cell is longer, occupying almost $\frac{3}{4}$ of the length of the wing; otherwise neurulation almost the same. The male imagines fly at noon in the sunshine around the tops of trees and are difficult to capture. The larvae exhibit magnificent spots on the 2nd and 3rd rings, 8 bicuspid thorns on the 3 first rings, 4 star-shaped tufts of spikes on each of the 6th to 11th rings, 3 of them on each of the 12th and 13th rings. They pupate in a pear-shaped cocoon which is open at one end. They all live in Chile.

Type: *P. rubescens* Blch.

rubescens. **P. rubescens** Blch. (= *andromeda* ♀ M. & W., *rhodocera* Prittw.) (104 c) is a very common species and of a rather variable colouring and marking. Forewing yellowish-grey with a large dark basal inner-marginal spot, 2 transverse bands the distal one of which projects between 2 and 4 with round projections almost to the margin and a somewhat oval eyespot between them. Hindwing dark orange, suffused with crimson in a variable extent, and with a carmine, white-centred ocellus and 2 narrow darker transverse bands. Common, but difficult to capture. The ♂♂ fly in the sunshine round the tops of trees between 12.30 and 2 p. m.; the ♀ flies at night. Chile.

andromeda. **P. andromeda** Phil. (104 c) is externally very much like *rubescens*, but easily discernible by the circular, not oval, ocellus on the forewing and the absence of the basal transverse line on the hindwing. The latter is reversely coloured, red, instead of orange in *rubescens*, and orange, instead of red in *rubescens*, the apex of the forewing is somewhat less produced than in *rubescens*. Antennae light red-brown, not black. Chile.

edmondsii. **P. edmondsii** Btlr. (= *andromeda* ♂ M. & W.) is very similar to *andromeda*, but the distal border of the distal transverse band is of a purer white; hindwing carmine, in the inner-marginal half of the disc and at the distal margin orange, the margin brown. The ♀ is lighter, more flesh-coloured, the disc outside olive brown. Common in March and April, the ♂ flies in the sunshine between 9.30 and 11 a. m. The stout grey larva with hair-pencils lives on roses and pupates in a widely meshed whitish silk-web. Chile.

cinerascens. **P. cinerascens** Phil. (= *apollina* Fldr., *albescens* Btlr.) (104 b) is easily discernible from the preceding species by the quite different duller yellowish-grey colouring without red, sometimes almost white. Scheme of markings otherwise the same. The rarest of the 4 species, flying between 9.30 and 11 a. m. Larva beneath

light green, above pinkish-grey, the magnificent spots velvety black, the thorns on the 4 first rings red, at the end black and yellow and ending in a white hair, the other spikes being yellow with black tips. The pear-shaped cocoon between leaves. Chile.

7. Genus: **Automeris** Hbn.

An immensely large genus of rather homogeneous species which have hitherto not yet been exactly differentiated and therefore offer many difficulties, especially since the denomination is very confused. They are mostly large beautiful lepidoptera with brightly coloured hindwings provided with a large discal ocellus. Antennae of ♂ broad, bipectinate, in the ♀ different, mostly filiform or feebly serrate, with bristles. Palpi rather well developed, reaching the frons or projecting beyond it; eyes rather large; proboscis sometimes recognizable as a feeble thin thread. Shape of wings mostly rather broad, apex of forewing more or less pointed, often falcate. Forewing with 3 subcostal branches, 7 and 8 on a long stalk, 10 shortly before it. 5 is removed down almost into the centre of the cross-vein; also on the hindwing 5 proceeds from below the upper cell-angle; 6 almost equidistant from 5 and 7, the costal vein terminates into the apex or before it, 7 into the distal margin or right below the apex. Larvae cylindrical with star-like bristled or spiked knob-shaped tubercles. The thorns produce a very severely burning sensation; nevertheless the larvae seem to be very much exposed to the attacks of ichneumonids. Pupation in cocoons with wide meshes.

Type: *A. janus* Cr.

A. janus Cr. is a well-known large species, forewing greenish-brown, finely strewn darker, the antemedian line very strongly undulate, feebly darker, the median area generally somewhat lighter, more violettish-grey, discal spot very large, in its proximal half darker, in the distal half lighter with single black vein-dots around it; postmedian line in the nomenclatural type undulate, shortly produced distally on the veins, blackish-brown, inside bordered with a lighter shade, the light subterminal line of the usual shape, marginal area distinctly greyish-violett. Hindwing in the disc yellowish-grey, basal area with rosy red hairs; ocellus very large, mostly somewhat oval, jet-black, towards the centre lighter yellowish-grey, in the centre dusted white, with a white angular transverse line; behind it follows a black thick line feebly dentate on the veins, then after a short distance a broad rusty red band. Margin violettish-grey. Ecuador, Venezuela, Eastern Colombia, Guiana. — **metzli** Sallé (= mestli Bsdv.) (106 a) is the more northern form from Mexico and Guatemala, mostly smaller on an average, the antemedian line less undulate, the postmedian line quite straight, the black dots in the surroundings of the discal spot much stronger, the discal spot in the middle often parted by a black transverse streak, the submarginal band of the hindwing of the same rosy red colour as the basal area. Ground-colour generally somewhat lighter, more yellowish-brown. — **collateralis** Hamps. is an aberrative form frequently occurring in both the preceding forms, in which the black arcuate line of the hindwing touches the very large ocellus; hardly worth while denominating it. Larva described to be so profusely set with strong tufts of spikes that it looks like a cluster of moss. The burning effect is uncommonly severe, so that it may produce dangerous injuries. Pupa in a very coarse and widely meshed reticulate cocoon.

A. beckeri H.-Schäff. (106 a) is somewhat like *janus* on the forewing, but the colour is more loamy brown, the antemedian line forms only 2 large bows and a very small one above the inner margin, the postmedian line is more distinctly double. Hindwing without any pink, basal area with long greyish-yellow hair, the very large eyespot loamy grey in the disc, almost blind, very scantily strewn with white in the centre, extended to the inner margin by black dusting. Both the transverse lines behind it broad, the interior line black, undulate, the exterior line composed of spots, in the ♂ mostly also black, in the ♀ sometimes reddish-brown. Abdomen loamy brown. Brazil.

A. egeus Cr. The ♂ is purple brown, the ♀ much lighter red-brown, in the median area and at the margin lighter violet; markings rather indistinct except the blackish brown postmedian line which is bordered with whitish-blue inside; eyespot of hindwing with a large iris of the ground-colour with a small black pupil, behind it the usual 2 black lines, the interior one near the ocellus, turning strongly analward before the inner margin, the exterior one very broad, smoky grey. The orange abdomen shows blackish rings at the base of the segments. Guiana to Southern Brazil. — **boops** Fldr. (106 b) is the form from Venezuela and Colombia. Discal spot much broader and larger with a blackish central dot, in the distal border with thick black triangles; marginal area somewhat narrower. Hindwing with more reduced though brighter orange basal hair. Ocellus larger, the yellowish-grey iris smaller, the black pupil larger, hardly strewn with white; thorax lighter red-brown. The figured Colombian specimen from the Berlin Museum matches it very well. — **zelleri** Grt. & Rob. (106 a) is said to originate from North America; it has never been heard of again from that country. In the Berlin Museum a ♀ was found exactly matching the diagnose, with a green label as "zelleri" found in "Texas", apparently written by GROTE, presumably the type which we figure. Basal and marginal areas dark brown, median area much lighter, suffused with violet, the large brown discal spot outside with 3 dents and a white

central dot, without black dots outside; the feebly curved postmedian line is light, on both sides bordered with dark, at the costal margin 2 cm distant from the apex; eyespot as in *egeus* with a white transverse streak in the small black pupil; subterminal band behind it outside straightly defined, in contrast with *egeus* and *boops* where it is outside undulate and more interrupted on the veins. Abdomen brownish ochreous.

postalbida.

A. postalbida Schs. is a large species allied to *egeus*, with a very light median and marginal area; the antemedian line forms 2 flat bows, with a little contrasting discal spot, marked by 5 black dots; postmedian line plain, almost straight, inwardly bordered by a feebly lighter colour, vanishing towards the costal margin; the dark subterminal area outside roundly bordered undulately. Hindwing almost white, the black pupil in the large ocellus strewn somewhat white with a white central streak. The ochreous abdomen with feebly dark ringlets. Balzapamba (Ecuador). — **niepelti** f. n. (106 b) is larger, the black antemedian line much more strongly undulated, in the cell and submedianly with 2 projections each towards the margin; discal spot tridentate with 4 black dots around it and a white central dot; postmedian line double, inside blackish-grey, outside purple brown, filled with light brown, almost straight, only slightly bending towards the base below the costal margin; subterminal line more dentate, the marginal area behind it as light as the median area. Hindwing very light grey with a feebly yellowish tint, almost the whole pupil of the ocellus thickly filled with white, the marginal area behind the two black lines densely strewn with greyish-brown, crossed by rusty yellow veins, the fox-coloured abdomen with broad black ringlets. Western Colombia (Bella Vista); type in Coll. NIEPELT.

niepelti.

larra.

A. larra Wkr. (= palegon *Bsdv.*) (106 b) differs from the preceding ones in the straighter postmedian line extending nearer to the apex and being filled with bluish-white; discal spot sometimes with a white central dot, but always with 4 dots below and outside. Hindwing of a somewhat more reddish tint, the eyespot in the centre with a larger black, white-strewn pupil, with a distinct white transverse streak, the two lines behind it black, the interior one plainly bent, the exterior one composed of thick black spots. Under surface brighter rusty brown than in the allies, with a large black discal spot. Brazil. — **panamensis** f. n. (106 c) from Chiriqui, is much darker red-brown, the distal half of the median area densely strewn with bluish-white, the postmedian line somewhat more curved, slightly concave towards the margin. The light yellowish-grey disc of the hindwing is very extensive, the ocellus large, especially the pupil very extensive with a thick white transverse streak, the distal one of the two lines behind it not divided into spots, but quite straight, the brown marginal area behind it narrow. Type: 1 ♂ in the Berlin Museum.

panamen-
sis.

cryptica.

A. cryptica Dogn. (108 a) has brown forewings with a white basal spot and somewhat darker brown straight transverse lines, on the inverted sides bordered with light violet, the inner line at the costal and inner margins equidistant from the base, the outer line at the inner margin rising close at the base and terminating far before the apex at the costal margin; discal spot rectangular. Hindwing light lilac, basally with ochreous hair, with a large eyespot with a blackish-brown iris and a black, white-strewn pupil, with a white transverse streak; behind it a broad black uniformly rounded subterminal band, behind it a whitish band before the violettish-brownish margin. Colombia.

banus.

A. banus *Bsdv.* (107 b). Thorax very dark brown, abdomen brick-coloured yellowish or ochreous. Forewing basally and in the marginal area olive brownish mixed with yellowish hair-scales, the median area somewhat purer brown, in the ♀ tinted violet and, like the anteterminal area, strewn with white; transverse lines darker, on the inverted sides strewn somewhat white, especially the outer line in the costal-marginal part. The darker discal spot with intense black marginal dots and a black central streak. Hindwing reddish brick-coloured, in the marginal area olive brown or yellowish-brown, densely strewn with white excepting the reddish veins. The large black ocellus with a greyish-yellow iris, in the black pupil strewn with white, with a white transverse streak; behind the black postmedian line, which is slightly interrupted on the veins, there is a red-brown nebulous band. Mexico.

amanda.

A. amanda Schs. (108 a) is very similar to *banus*; head and thorax dark velvety brown, abdomen light reddish-brown with darker segmental margins. Forewing more unicoloured violettish-brown, the fine lines darker; the interior oblique line from the costal margin to the median vein, then inwards and, on the submedian fold, turning outward again; the large discal spot indistinct, marked by dark dots, the distal line straighter than in *banus*; hindwing light reddish-brown, the light brown, large ocellus with a black ring contains an oval black pupil surrounded by white, and a white central line; distal margin violettish-brown with 2 brown distal lines. Expanse of wings: 86 mm. Bolivia.

proximus.

A. proximus Conte (= *ecuadora* *Weym.*) (108 a) is very similar to *amanda*, darker brown, much more intensely strewn with white, especially in the median area, the grey discal macula very densely strewn with white, the postmedian line towards the costal margin somewhat undulate-dentate, inside bordered with an intense white. Disc of hindwing more yellowish ochre; above all separable by the broadly black-curved ochreous abdomen. Ecuador, Colombia. WEYMER's type of *ecuadora* is before me from the Berlin Museum, it belongs to this species and has nothing to do with the figure by STRAND in Lep. Niepeltiana, which belongs to *erisichton* (cf. ib. p. 733).

oweni.

A. oweni Dogn. is likewise rather near to *banus*, the forewing is more yellowish-grey, with the 2 transverse lines and the well marked discal spot. Hindwing beautifully orange, at the inner margin with orange hair; the ocellus is very large, somewhat flattened, with a yellowish-grey iris enclosing 2 black, white-strewn pupils

of unequal size, the larger one is parted by a grey vein and shows a white transverse streak, the smaller one being above it; behind the ocellus follows a black undulate line and outside a grey, rather indistinct line disappearing in the grey distal margin. Thorax dark brown, abdomen beautifully yellow. Described according to 2 ♂♂ from Zamora (Ecuador).

A. subpictus Dogn. (= *colombianus* Bouv.) (108 b). Head and thorax blackish-brown, abdomen *subpictus*. brown with single ochreous hairs. The brown forewing is strewn with white basally and in the median area; transverse lines darker, the posterior line from close behind the centre of the inner margin to 5 mm before the apex, proximad strewn with white; the dark discal spot is oblong, in places marked with black. Hindwing light olive or yellowish ochreous, the large ocellus with a dark olive iris and 2 or 3 black, white strewn and bordered pupils, the middle one being the largest, the anal one mostly only a narrow white streak, or absent altogether; behind them there is a double fine, feebly dentate subterminal line, distally dusted with white as the brown marginal area. Colombia (Bogota).

A. subobscura Weym. I do not know in nature, it may belong to *subpictus*, but it has an ochreous ab- *subobscura*. domen with broad dark brown rings and is therefore also similar to the following *abdominalis* from which it is said to differ in the more pointed apex of the forewing, the unicoloured marginal area, and the broad brown margin of the hindwing extending to the yellow disc, whilst in FELDERS species the yellow colour extends far into the marginal area. Forewing brownish-grey, in the median area lighter, at the costal margin and distal margin darker; postmedian line straight, dark brown, proximally bordered with whitish-grey, from the apex to $\frac{3}{4}$ of the inner margin; discal spot brown, round, with 3 black dots in its edge. Hindwing dark ochreous, with a large brownish-grey ocellus in a black ring of 2 mm width, and a pear-shaped black pupil with a white transverse streak; the brown distal margin is traversed by 2 whitish-grey lines. Under surface conspicuously dark blackish-brown. Bogota (Colombia), described according to a ♀.

A. denticulatus Conte (= *moerens* Jord.) (107 c) is quite different, but it resembles the *banus*-group *denticulatus*. by the hindwing with the pale olive brown ground and the abundant white strewing at the base, median area and distal margin of the forewing; separated by the undulate-dentate postmedian line which is bordered with white on both sides; subterminal area especially in the lower half angularly projecting into the white-strewn margin; ocellus of hindwing with a but very small white-powdered pupil; the exterior one of the two subterminal lines is broad, analward likewise angularly projecting. Thorax blackish-brown, abdomen and base of hindwing ochreous. Peru; Ecuador (Sarayacu).

A. despicata sp. n. (108 b) is allied to the *banus*-group to a certain degree. Thorax dark brown, abdomen *despicata*. dull ochreous; forewing unicoloured dull olive brown, anterior transverse line extremely feeble, whitish, extending as in *proximus*, the posterior line hardly more distinct, straight from the last third of the inner margin to 3 mm before the apex, in front of the apex with somewhat whitish, scanty hair-scales; discal spot slightly darker than the ground-colour, in its lower border a dark brown arcuate streak, outside 2 black dots in the middle and in the upper angle; subterminal line feebly lighter, undulate, behind it scantily strewn with whitish. Hindwing in the disc dull reddish ochreous, the large ocellus, which is relatively narrowly edged with black, with a very extensive olive brown iris and a small, intensely white-strewn pupil with a white transverse streak; the ocellus shows distally a very feeble and narrow light yellow border closely followed by a fine black undulate line, proximally narrowly bordered by yellow, the marginal area being olive brown, traversed by a whitish undulate line. Beneath the straight postmedian line of the forewing ends 1 cm before the apex, on the hindwing it is likewise straight passing close behind the white discal spot. According to a ♀ from Chuchuras (Eastern Peru) in the Berlin Museum.

A. abdominalis Fldr. I only know from FELDER'S figure; it has a more obtuse apex of the forewing than *abdominalis*. the preceding species, with a lighter violettish-grey marginal area, and besides the marginal area on the hindwing behind the black undulate line is reddish ochreous excepting the extreme brownish margin and a brownish transverse band passing through; the brown discal spot of the forewing shows a whitish central spot. The ochreous abdomen exhibits dark brown rings. Likewise from Bogota. According to the figure I should consider the species to be *illustris* with a somewhat darker ringed abdomen, as it is also shown on our figure of *illustris*.

A. illustris Wkr. (= *coffea* Bsd., *pelotas* Strd.) (107 a) is very closely allied to the preceding species *illustris*. and especially also to *rubescens* and its allies; on an average somewhat larger, the discal spot duller, with hardly or without any black dots surrounding it. Hindwing yellowish-red, the ocellus without the distal yellow ring, the undulate subterminal line neither bordered inside with yellow. Larva green with yellow branched thorns causing a fiercely stinging pain, with a light lateral stripe and small dark transverse spots above it; it lives on various trees and shrubs, especially Melastomaceae and Rubiaceae, on coffee, magnolias; and many others. Common in Brazil. The type of *pelotas* has been lying before me by the kindness of Dr. HORN; it undoubtedly belongs to this place.

A. pyiades Bsd. (107 b) is larger than *illustris*, with a somewhat paler ground-colour, in the ♀ more *pyiades*. greyish reddish, the discal spot forming outside 3 more or less distinct dents. Hindwing light reddish-ochreous, ocellus very large, with a very extensive olive brownish iris and a thickly white-strewn pear-shaped pupil with a distal point; the fine subterminal line behind it is undulate, then follows a brownish ochreous band and, separated by a narrow whitish space, the brownish marginal area. Thorax dark brown, abdomen ochreous. Brazil.

chacona. **A. chacona** *sp. n.* (108 b) is very near to *illustris*. Thorax dark brown, abdomen bright ochreous. Forewing densely strewn with brown on the ochreous ground, transverse lines very feeble, yellowish, the posterior one ending 6 mm before the apex; discal spot marked by 4 dots, with a narrow blackish central shadow; subterminal line marked by the contrast of the darker interior portion with the more yellowish marginal portion. Hindwing bright ochreous; ocellus very large with a very extensive brown iris and a small black, white-strewn pupil with a white bar crossing it; close behind the ocellus and touching it a thick black, very arcuately dentate line reaching neither to the costal nor inner margins, the reddish ochreous area behind it crossed by 2 brownish bands, the interior band being undulate. Described according to a ♂ from Chaco, La Paz (Bolivia), from the Berlin Museum.

pictus. **A. pictus** *Conte* (= *parilis* *Schs.*) (107 a) is likewise near to *illustris*, the transverse lines on the forewing are closer together, on the inverted sides bordered with yellowish, the anterior line only produced on the median vein, the posterior line feebly curved, arising 6 mm before the apex as far as about $\frac{2}{3}$ of the inner margin; discal spot dark grey. Hindwing light reddish, the ocellus distinguished by a very large black pupil parted by a white bar; behind the undulate black subterminal line a violettish-brown band. The ♀ is light purple brownish, in the discal area lighter lilac, the pupil of the ocellus may have a diameter of up to 8 mm, strewn with white with a large white central spot. The colours of our figure are too dull, as in all the figures of plate 107. Cayenne; also from Peru.

rubescens. **A. rubescens** *Wkr.* (105 d, 106 c) is a more common species distributed from Mexico and Guatemala to Venezuela. Forewing light brown mixed with yellow, the most contrastingly so in the marginal area; the yellow-edged antemedian line projects distally on the median vein and the submedian fold, the blackish discal spot is mostly white-centred and projects pointedly outside in the middle, often marked with 3 black dots, the yellowish postmedian line feebly bent, powdered with white below the costal margin, where it forms 2 flat bows. Hindwing brownish red, the large ocellus in a narrow yellow ring, with a pale brown iris and a black, densely white-strewn pupil with a white bar crossing it, behind it a black undulate line bordered with yellow on both sides, the marginal area yellowish brown. Thorax dark brown, abdomen orange brownish. The ♀ shows much darker, purple brown forewings.

nopaltzin. **A. nopaltzin** *Schs.*, described according to a ♀ from Paso de San Juan (Vera Cruz, Mexico), is very closely allied to *rubescens*, and I believe that it is probably only an aberrative specimen of it with a tripartite pupil; before me there is 1 ♀ with a bipartite pupil, which otherwise exactly corresponds with the diagnose and, excepting the ocellus, cannot be separated from the long series of *rubescens*-♀♀ from Mexico before me. Forewing violettish-brown, the postmedian line bordered with yellow. Discal spot with a white central dot; easily discernible by the ocellus on the hindwing, in the brown iris of which the pupil is divided into 3 parts, as in *liberia*, the largest middle spot with a white transverse line; ocellus with a yellow ring, the black subterminal line behind it indistinct. Expanse of wings: 80 mm. With *Conte* the signatures of the figures of *nopaltzin* and *menusae* have been exchanged.

moloneyi. **A. moloneyi** *Drc.* resembles *nopaltzin*, but it is smaller, the yellowish-brown ground-colour of the ♂ contrasts with the purple brown basal area and discal spot; the basal area is defined by a narrow brown line outside bordered with yellow; the postmedian line is likewise brown, proximad yellow, and it extends almost straightly from near the apex to the inner margin, and is powdered with white above; the very faint undulate submarginal line is likewise yellow. Hindwing darker red brick-colour, otherwise marked as in *rubescens*, but the ocellus is smaller. The ♀ is darker red-brown, the marginal areas in both wings dusted with white. From British Honduras.

godarti. **A. godarti** *Bsdv.* corresponds with *rubescens* in the marking, but it is smaller; ground-colour lighter reddish-brown brick-colour, only the narrow marginal area more yellowish; the brown discal spot is marked with 5 black dots. Hindwing yellowish-red, the iris of the black-edged ocellus of the same colour, the small black pupil with a white streak, the black undulate line behind it only proximad slightly bordered with yellow. Before me there is a specimen e coll. BANG-HAAS corresponding with the figure of the ♂ in the coll. OBERTHÜR. *Conte*'s figure of the ♀ certainly belongs to another species.

randa. **A. randa** *Drc.* (105 d) is likewise very closely allied to *rubescens*; larger, marginal area and transverse lines, less marked with yellow, the lines outside more broadly strewn with blackish, the discal spot surrounded by 5 black dots, with a fine black central streak which is often inwards bordered with white. Hindwing of a brighter yellowish-red brick-colour, with a larger ocellus lacking the yellow ring, the brown iris and the white strewing of the pupil more extensive; the line behind it broader, less undulate, and only inwardly bordered with yellow, marginal area browner. From Mexico and Guatemala.

zurobara. **A. zurobara** *Drc.* (105 d). We figure the type from the Berlin Museum. Forewing brown, the basal area, the short oblique shadow from the costal margin, and the subterminal shadow darker; transverse lines as in *rubescens*, feebly bordered with yellowish; the discal spot showing through from beneath has a whitish dot in the centre. Hindwing unicoloured reddish brick, also the iris of the ocellus which shows a relatively narrow black border, with a large black pupil, with a white transverse streak and very scantily strewn with white; the fine black undulate line is proximad hardly visibly bordered with yellow. Thorax not darker brown than the basal area of the forewing. Panama (Chiriqui).

A. cinctistriga Fldr. (105 d), likewise closely allied to *rubescens* and *randa*, is smaller, in the male *cinctistriga*. lighter, the transverse lines are yellow, the postmedian line uniformly bent, outside bordered with greenish-brown, scaled white below the costal margin, discal spot with or without fine black dots. Hindwing yellowish-red brick-colour, ocellus as in *zurobara*, the pupil more intensely strewn with white, outside with a narrow yellow ring, the fine black slightly undulating subterminal line inside bordered with yellow, the marginal area somewhat lighter, more yellowish. The ♀ is somewhat darker, more reddish-grey, the transverse lines more broadly bordered with dark, the basal area feebly dusted with whitish; it thereby recalls *coresus*-♀. Central America, to the north as far as Mexico.

A. aristei Dogn. has reddish yellowish-brown forewings with darker transverse lines, the anterior line *aristei*. straight, only incurved on the median vein, the posterior line from shortly before the apex to $\frac{2}{3}$ of the inner margin, inwardly white-scaled; discal spot oval with black dots around it and a white-scaled centre, the marginal area somewhat lighter. Hindwing coloured as forewing, but somewhat lighter, with a large somewhat oval ocellus, iris brownish, pupil black, powdered with white, with a white central dot, behind it a thick black, slightly dentate line and a similar brown submarginal line. Thorax blackish-brown, abdomen above brownish with reddish ochreous rings. A large species with an expanse of 102 mm, described according to a single ♂ from Bogota.

A. crassus Conte is most closely allied to the *rubescens*-group and was described according to a single ♂ *crassus*. from French Guiana. Front body dark brown, abdomen brick-coloured red. Forewing yellowish dark brown, basal area browner, the notched antemedian line yellow, discal spot likewise with a notched black-dotted border, blackish, darker centred; the fine postmedian line from close before the apex, brown, inside bordered with yellowish, the narrow marginal area behind the subterminal lines yellowish-brown. Hindwing dark brick-red, ocellus large, brownish grey, broadly edged with black, with a feeble yellow ring, a black pupil with a white transverse bar, and strewn with white, the black line behind it hardly undulate, on both sides bordered with yellow, then a brown band, marginal area yellowish greyish-brown. Expanse of wings: 90 mm. A ♂ from Eastern Colombia corresponds well with it.

A. tridens H.-Schäff. (108 c) is above brownish ochreous, the marginal area of a purer yellow like the *tridens*. transverse lines, the posterior line almost from the apex; the brown discal spot is often tridentiform outside, the points sometimes marked by black dots. Hindwing reddish with a black ocellus in a narrow yellow then again fine black ring, with a yellowish-grey iris and a tiny white or grey pupil; behind it an undulate-dentate black line bordered with yellow. Thorax brown. The ♀ is purple brown, dusted with lilac. Well recognizable by the almost blind ocellus. Brazil.

A. amoena Bsdv. (108 b) is separated from the allied species by the large black ocellus with a yellowish-grey iris and a black pupil enclosing a white angular streak. Forewing reddish greyish-brown, in the ♀ more purple brown, with a darker base and yellow transverse lines, and a brownish discal spot; the postmedian line begins 5—6 mm distant from the apex. Hindwing yellowish-red, behind the ocellus an undulating black line, behind it a red-brown band. Thorax brown, abdomen yellowish-red. Cayenne.

A. jucunda Cr. (106 c). Forewing of ♂ reddish-brown, of ♀ purple brown dusted with violettish white, *jucunda*. with a white basal spot and a whitish postmedian line almost parallel to the margin, starting a little before the apex; the antemedian line is only marked by white strewing behind the darker basal area, the discal spot and a short oblique band behind it darker. Hindwing brick-red or brownish-red with a yellow-ringed ocellus, a brownish iris and a black, white-strewn pupil; the black undulate line behind it is inside bordered with yellow. Abdomen brick-red. Guiana to Brazil.

A. divergens Bsdv. (= *jucunda* Cr. ♂ 249 A) being a ♂ does not at all fit to the figure of *jucunda*-♀; *divergens*. much smaller, rusty brown, with a broad yellow antemedian band, a black discal spot, and a yellow spot behind it; postmedian line and the ends of the veins behind it yellow. Hindwing rusty yellow with an oval ocellus, the iris of the ground-colour, the pupil black, strewn with white; behind the ocellus a short black arcuate streak, marginal area. Surinam. I have not seen anything similar, but according to the figure it seems to be allied with one of the two following species.

A. junonia Wkr. (108 c). Forewing of ♂ brownish yellow or also purely yellow, as in *tridens* with *junonia*. brownish ochreous transverse lines bordered with yellow on the inverted sides, the anterior line very sinuous, on the median vein and submedian fold distally pointedly notched; discal spot and often also the basal area dusted with lilac brownish, the former spot with four black dots and a curved blackish central line; postmedian line from shortly before the apex. Hindwing yellowish-red with a large black, yellow-ringed ocellus, a brownish iris and a large black, white-strewn pupil enclosing a white transverse bar; behind it is followed by a fine undulating line inside bordered with yellow which colour may also be confluent with the yellow ring of the ocellus. Marginal area yellow. The ♀ is reddish-brown, dusted with violet, the discal spot occasionally white-centred. Body ochreous. Mexico.

A. titania Fldr. (108 c). It is questionable whether this species is to be regarded as a form of the *titania*. very similar *junonia* or as a distinct species. Mostly somewhat smaller, of a brighter golden yellow colour, and easily discernible by entirely red hindwings, the ocellus not yellow-ringed, the black stripe behind it neither inside bordered with yellow, mostly outside touching the red band without a yellow intermediate line. Colombia.

- moresca*. **A. moresca** Schs. Head and thorax dark brown, abdomen light reddish. Forewing lilac brown, behind the cell and at the distal margin lighter reddish-yellow; the dark discal spot irregular, surrounded by black dots; the dark postmedian line is inwards bordered with reddish-yellow and extends from near the apex almost to the anal angle. Hindwing light reddish, at the margin lilac brown, with a large ocellus with a greyish-brown iris and a black, white-strewn pupil with a white transverse bar; behind it a fine black undulate line, inside yellow, behind which a red-brown shadow follows. Expanse of wings: 78 mm. French Guiana.
- oblonga*. **A. oblonga** Wkr. is a very large species, as large as *egeus*, in the ♂ the forewing is light yellowish red-brown, at the costal margin dusted with greyish-white, in the ♀ browner, the transverse lines light yellow, the anterior line notched, the posterior line straight, the marginal area is yellow, the discal spot oblong, brown. Hindwing reddish, in the distal half light yellowish, with an oval ocellus with a reddish-brown iris and an oblong black pupil with a white bar, behind it with 2 undulate bands, the interior one light brown, the exterior one light fawn. Body and thorax coloured as forewing. Bogota.
- jucundoides*. **A. jucundoides** Schs. Head and thorax red-brown, abdomen brownish-yellow. Forewing in the basal area light red-brown, at the base dusted with lilac, in the median area light lilac brown, with a blackish discal spot; the fine light reddish-brown postmedian line proceeds from near the apex: marginal area light brownish ochreous with a lighter subterminal shadow. Hindwing light reddish with a large light brown black-ringed ocellus in a yellow ring, instead of the pupil only with scanty white and grey scales, the line behind it being short. Expanse of wings: 63 mm. A small species from French Guiana.
- themis*. **A. themis** Dogn., described according to a ♂ from French Guiana, is very similar to *oblonga* and differs from it in the deep chocolate-brown thorax and the almost entirely black ocellus; abdomen ochreous. Forewing reddish-ochreous, with yellowish ochreous transverse lines; the posterior line from close before the apex to the inner margin, about half a centimeter before the anal angle; discal spot not darker, but finely edged with light with a few black dots and a white central dot; marginal area yellowish ochreous like the lines. Hindwing basally and at the costal margin and inner margin pinkish ochreous; the oblong black ocellus, only in the centre olive brown with a white central dot, is situate in a yellow circle touching the short black postmedian line, behind it before the reddish ochreous marginal area with a red-brown subterminal band.
- tamphilus*. **A. tamphilus** Schs. (107 a) is light reddish-brown on the forewing, at the distal margin yellowish; transverse lines somewhat lighter than the ground, the distal line from close before the apex to $\frac{3}{4}$ of the inner margin. Hindwing yellowish-red, at the margin lighter, the ocellus relatively small, brown, black, then narrowly yellow-ringed, in the centre a tiny grey spot with a white bar, the black subterminal line behind it inside finely bordered with yellow. Head and thorax dark brown. Forewing of ♀ more purple brown, dusted with lilac whitish. Brazil (Rio de Janeiro, Joinville).
- belti*. **A. belti** Drc. (= *zaruma* Schs.) (108 d) is a larger, very beautiful species, larger than *randa* which it resembles on the forewing, the discal spot which is somewhat narrower than in *randa*, a little more conspicuous, especially the black marginal dots more distinct. On the hindwing at once discernible by the extensively lemon-coloured disc enclosing the large, broadly black-edged ocellus; behind it a thick black line and a black band. In the ♀ the concave postmedian line is very distinct. Panama; Nicaragua.
- excreta*. **A. excreta** sp. n. (107 c) is a large species from Mexico, which seems to have been hitherto mistaken for *belti* or also *averna*, but which proves to be entirely different on being compared with the type of *belti*. Body as in *belti*, but abdomen redder. Forewing of ♂ densely strewn with brown on the ochreous ground, the ante-median line more notched, outside brighter yellow like the postmedian line which is straighter and outside not so contrastingly darkened. The red colour of the hindwing is more ochreous, not so crimson, the lemon-coloured disc and the ocellus more reduced, the latter as in *belti*, the black line not so thick, the band behind it red-brown, not black. The ♀ more purple brown, strewn with lilac white, the transverse lines, however, distinctly bordered with yellow. Types (♂♀) from Orizaba in the Coll. DRAUDT. In the figure the colours are much too dull, the yellow and red of the hindwing ought to be bright and distinctly defined. *averna* is a much smaller species, only as large as *boucardi*.
- macphaili*. **A. macphaili** Schs. (107 c) is somewhat smaller, in the ♂ the wings are shorter and broader, on the forewing the black postmedian line is distinct, especially in the ♀ inwardly somewhat lighter, more incurved than in *belti*, and beginning farther away from the apex, on the hindwing the yellow disc extends somewhat farther basad, the black postmedian line is thicker and not undulating. Abdomen red, in the ♀ more reddish-ochreous. Guatemala.
- foucheri*. **A. foucheri** Bouv. (108 d) is exactly as *macphaili* on the hindwing, but the disc is more pinkish, whilst the forewing exhibits the three black discal spots of *maculatus*, thus a most characteristic, unmistakable species. Colombia.
- liberia*. **A. liberia** Cr. (= *megalops* Wkr.) (107 c) is allied to the *rubescens*-group; colour of forewing varying between yellow and brown, transverse lines somewhat darker, the posterior line more or less incurved, towards the costal margin inside slightly scaled whitish, discal spot grey, distally extended in 3 more or less distinct dents; subterminal line and marginal area mostly of a purer yellow. Hindwing with a yellowish-red disc and

a large ocellus surrounded by black, iris light olive brownish or reddish, the pupil divided into 3 spots, the middle one being the largest, pear-shaped, parted by a white bar; the blackish line behind it rather fine, undulate-dentate, behind it a broader brownish line; marginal area coloured as forewing. The ♀ has browner forewings, the yellowish-red abdomen mostly curled brownish. Venezuela, Guiana, Colombia, Brazil, Peru. The green larva with bluish-green branched thorns, oblong yellow sublateral spots and a brown last ring lives on species of Citrus.

A. erisichton Bsdv. (= *ecuadora* Strd. nec Weym.) (107 d) is very similar to *liberia*, somewhat smaller, *erisichton*. more brownish-grey and more coarsely strewn, the transverse lines are more clearly outlined as distinct dark lines and not lighter on the inverted sides; the anterior line is almost straight and runs vertically to the inner margin, the posterior line is much more remote from the margin than in *liberia*, so that the median area is much narrower especially at the inner margin, the subterminal line is less sinuate. Ecuador. The figure supplied by STRAND in Lep. Niepeltiana, pl. XII, fig. 4, belongs to this place here and has nothing to do with the type of WEYMER's *ecuadora* lying before me (cf. *proximus* CONTE, p. 728!).

A. falco Jord. (108 c) resembles *liberia* in colour and marking, but the apex of the forewing is longer *falco*. and falcately extended, the black abdominal belts are broader. On the forewing the discal spot is surrounded by 4 thick black dots, 3 outside, one inside below; exterior transverse line nearer to the margin, inside narrowly bordered with yellow. On the hindwing the brownish loam-coloured marginal band is somewhat narrower at the anal angle than in *liberia*. From South-Eastern Peru (Carabaya), described from 2 ♂♂, in the Berlin Museum from Bogota.

A. coresus Bsdv. (107 d) is a common, well-known species from Southern Brazil, Argentina, and *coresus*. Paraguay. Forewing brown, basally dusted with white; transverse lines convergent towards the inner margin, the anterior line distally angled on the median vein, the posterior line about 5 mm before the apex with an inward bow, dark, on the inverted sides bordered with whitish or yellowish; the blackish or also whitish dusted discal spot shows black dots inside and outside, and a blackish central bar or dot; the oblique shadow behind it is very broad and dark like the subterminal area. Abdomen and hindwing in the disc yellowish-red with a large black-ringed ocellus with an extensive dark olive brown iris and an intensely white-strewn pupil and a more or less distinct white transverse bar; the black line behind it broad and undulating, behind it a rather broad brown nebulous stripe. Larva green with a white lateral line being above bordered with black, above the stigmata violettish-black small spots which are bordered with white below, with fir-tree like green thorns. The larva burns severely on being touched and is common on all kinds of trees in gardens and avenues.

A. maculatus Conte (= *curvilinea* Schs.) (107 d) is hardly to be mistaken for any other species. Forewing *maculatus*. of ♂ brown, of ♀ dark grey, antemedian line blackish-brown, straight and almost vertical on the inner margin. Postmedian line forming a large inward bow, behind it an almost straight, nearly just as dark subterminal line; discal spot darker brown, above and below with velvety black spots, a smaller third spot may be present outside, or also absent. Hindwing of ♂ orange, of ♀ dark olive grey, with a very large, broadly black-ringed ocellus with an olive brown iris and a very small white-strewn pupil; the interior subterminal line is broad, black, the exterior one narrower, brown. Abdomen reddish, with black bands. Guiana, Amazons (S. Paulo de Olivença), Peru.

A. phales Bsdv. is only known to me from the figure by CONTE from the Coll. OBERTHÜR. Forewing *phales*. rusty yellowish-brown, antemedian line yellowish, postmedian line slightly bent, likewise yellowish, somewhat undulate towards the apex; discal spot brownish, indistinct, with small black marginal dots; marginal area somewhat lighter. Hindwing yellowish red-brown, with a large yellowish-grey ocellus, broadly edged with black and with a white pupil; interior subterminal line undulate, black, exterior line brownish, indistinct. Thorax brown, abdomen yellowish-red. "South America."

A. flavomarginatus Conte (= *morescoides* Bouv.) (108 c) is a smaller species, forewing reddish-brown, *flavomarginatus*. basal area browner, the light brown antemedian line is dentate and distally dusted with yellow, the oblong brown discal spot white-centred; postmedian line deeply concave, terminating into the apex, brown, inside bordered with yellow; subterminal area brownish, marginal area lighter and more yellowish. Hindwing reddish-yellow, ocellus brown, narrowly bordered with black, the large pupil black, oblong with a large white spot and some white strewing, the black line behind it feebly undulate, behind it a dark brick-red band, margin violet. Chiefly separable from *phales* by the smaller and more oval ocellus. New Grenada.

A. sinuatus Conte is very similar to *flavomarginatus*, somewhat larger, of a lighter and more yellowish *sinuatus* ground-colour; the antemedian line outside more broadly bordered with yellow, the discal spot white-centred; postmedian line almost straight, terminating at the costal margin about 4 or 5 mm before the apex. Hindwing rusty yellowish-red, ocellus somewhat oblong, the narrow black ring bordered with yellow; the black undulate line inside somewhat yellow, behind it a red-brown band. Expanse of wings: 78—90 mm. From New Grenada, French Guiana.

A. ovalina Conte (109 a) is allied to the following *zozine*, but much smaller, the postmedian line much *ovalina*. deeper concave, and inwards, especially towards the inner margin very broadly bordered by pinkish white, the antemedian line being quite absent, the disc of the hindwing yellow, the base and inner margin red-haired; ocellus oval, pupil densely strewn with white, the undulating black line behind it broad, distally bordered with yellow, behind it follows a broad chestnut-brown band, margin lighter. Abdomen pink. South America?

- flammans.* **A. flammans** Schs. resembles *ovalina*, but it is much larger, with relatively narrow wings. Body pinkish brown like the wing; forewing with a yellow oblique line from the apex to the centre of the inner margin, and an indistinct discal spot, antemedian line absent. Hindwing smoky brownish-grey, costal and distal margin brownish-pink, border and fringe light brown; ocellus black with a reddish-brown pupil and a white centre, in a deep yellow ring, behind it a black undulate line. Type a ♀ with an expanse of 102 mm, from Colombia.
- obscura.* **A. obscura** Schs. (109 c), owing to the similar marking, is ranged best near *flammans*. Wings relatively thinly scaled, blackish, strewn with golden brown hair-scales; the undulate antemedian line indistinct, discal spot large, extinct, the black straight postmedian line from close before the apex to the centre of the inner margin. Hindwing similarly coloured with a black, uniformly bent distal line and a feeble dark discal spot. The ♀ is still more thinly scaled and more indistinctly marked. Brazil.
- zozine.* **A. zozine** Drc. (109 a). Ground-colour brown, variable, warming into olive, coffee, or reddish, antemedian line with two bows, discal spot slightly darker than the ground, feebly marked with black, postmedian line very feebly bent, outside bordered with whitish or reddish-grey, which colour covers more or less the whole marginal portion. Subterminal line shadow-like. Hindwing at the costal and distal margins like the marginal area of the forewing, inner margin with claret-coloured hairs, disc deep yellow; ocellus of medium size, broadly surrounded by black, in the disc variably strewn with white. Inner subterminal line black, slightly undulate, exterior line broader, brown. Abdomen yellowish-grey, above black, basally with claret-coloured hairs. In the Coll. DRAUDT a hybrid, size, colours and marking of wings exactly middling between ♂ and ♀, antennae to the left ♂, to the right ♀, abdomen stronger than in the ♂, though not quite reaching the ♀ volume, with ♂ clasp-organs. Mexico, a common species.
- melanops.* **A. melanops** Wkr. (= *brasiliensis* Bsdv. nec Wkr., *euryopa* Mschr.) (109 a) is very similar to *zozine*, somewhat larger on an average, mostly redder, apex of forewing more falcate, discal spot generally somewhat more distinctly outlined, postmedian line outside not so distinctly bordered with light, the short-subapical oblique band to it more distinctly marked. Ocellus of hindwing larger, whereby the yellow disc is reduced. In Brazil everywhere common, also in Colombia. It is impossible that the figure supplied by CONTE in his Essai, pl. XXI, fig. 3, which is undoubtedly a species from the *hübneri*-group — probably *amphirene* Bsdv. —, really belongs to *melanops*; the description is entirely different.
- nebulosus.* **A. nebulosus** Conte (109 a). Front body dark red-brown, abdomen pinkish-red. Forewing red-brown, basal area darker, central area somewhat lighter, the large oval discal spot darker, bordered with black; postmedian line straight, ending far before the apex, inwardly bordered with white. Disc of hindwing yellow, base and inner margin extensively pink-haired; the large ocellus almost quite brownish-black, in the centre strewn somewhat white, without a black pupil, with a broad black ring; the black line behind it broad, not undulate, outside with a somewhat yellow border, behind it a pinkish-brown band, the margin light brown.
- elegans.* Expanse of wings: 7 cm. South America? — **elegans** Conte is presumably only a variable specimen, separated by a grey discal spot of a more angular shape, and a smaller ocellus.
- basalis.* **A. basalis** Wkr. (110 a) is well recognizable by the peculiarly dull colouring; forewing light brown, in the median area somewhat lighter, at the base a yellowish-white spot, the dull brown discal spot white-centred, the lines fine, the posterior line often strong, extending from 5 or 6 mm before the apex behind the centre of the inner margin, inside feebly bordered with a lighter colour. Hindwing dull brown, at the inner margin sometimes with a very feebly pink tint, in the disc dull reddish-yellow, the ocellus very dull, brown, gradually warming into the blackish ring, in the centre strewn with white, with a white transverse bar; behind the black undulate distal line a very broad brown band, margin lighter. Abdomen very dull pinkish brown. Venezuela to Brazil.
- boucardi.* **A. boucardi** Drc. (109 a) is extraordinarily similar to *zozine*, somewhat larger, abdomen longer, forewing more reddish, more coarsely scaled, the marginal area not so contrastingly light, but the median area rather lighter, discal spot outside in the middle more prominent, more distinctly marked, postmedian line outside not so light. Hindwing more extensively claret-coloured, the marginal area narrower, with more prominently
- violacea.* dark veins. Costa Rica. — **violacea** Conte, based upon a ♀, exhibits a darker violettish brown ground-colour of the forewing, the hindwing also showing a violet tint except the yellow disc.
- zugana.* **A. zugana** Drc. is somewhat smaller, of a lighter and more yellowish ground-colour, the abdomen is black above and shows yellowish ochreous bands. Disc of hindwing dull yellow, with dull rusty red hairs at the base and inner margin, the ocellus of medium size, behind it a rounded black line and then a brown band. From Panama (Chiriqui).
- jivaros.* **A. jivaros** Dogn. (109 b) is likewise very similar to the preceding species, but at once discernible by the inner margin of the hindwing not being red but black. On the forewing the somewhat more curved postmedian line is more prominent, outside less light; the interior subterminal line of the hindwing is broad black, little undulate. Ecuador; Peru.
- vinosus.* **A. vinosus** Conte (= *meridana* Schs.) (109 b) is distinguished by relatively broad forewings, light reddish-brown, dusted with olive, the transverse lines on the inverted sides bordered with ochreous; discal spot

somewhat more quadrangular, grey; postmedian line from close before the apex, slightly inwardly convex to the inner margin behind the centre. Hindwing at the costal and distal margin coloured as forewing, inner margin broadly reddish-haired, disc dark yellow, the interior subterminal line feebly undulate, exterior line brownish-violet; ocellus of medium size as in *zozine*. Abdomen above red. Venezuela.

A. averna *Drc.*, described from a ♀, is somewhat larger than *meridana*, brown with a pink tint, behind the postmedian line darker, the latter inwardly bordered with yellow, originating 4 mm before the apex; discal spot large, blackish, with a white central dot. Hindwing light pinkish-brown, in the disc ochreous; ocellus with an extensive brownish-red iris and a black, white-dusted pupil with a white cross-bar; interior subterminal line thick black, exterior line a broad brown band. Abdomen brownish pink. Mexico.

A. pallens *Conte* (= *annulata* *Schs.*) (109 b). Body above dark olive brown, abdomen curled whitish. Forewing olive brown as far as the postmedian line, behind it reddish yellowish-grey; anterior transverse line fine, brown, straight in an oblique direction to the median vein, then undulate to the inner margin, the posterior line straight from the apex to the centre of the inner margin, at the cell-end a dark circular line with a dark central dot. On the hindwing the costal margin and the marginal area broad grey, inner margin olive brown, the disc bright yellow as far as the black, little undulate interior subterminal line, the exterior line forming a broad brown shadow; ocellus blackish-brown, broadly edged with black and in the centre scantily strewn with white. Expanse of wings: 74 mm. British-Guiana.

A. vomona *Schs.* (109 b). Wings broad, light red-brown, abdomen above black, the posterior margins of the abdomen narrowly reddish. On the forewing the antemedian line is rather indistinct, the postmedian line from shortly before the apex slightly bent to the centre of the inner margin, dark greyish-brown, inwardly yellowish ochreous; discal spot slightly darker than the ground, surrounded by some black dots. Hindwing in the disc yellow, at the costal and distal margins pinkish-brown, base and inner margin broad red; ocellus dark brown, broadly edged with black, in the centre white scales; interior subterminal line black, rather broad, behind it a reddish nebulous band. Venezuela.

A. pupilla *sp. n.* (109 b) is similar to *vomona*, with still broader greyish-brown wings, postmedian line from 3 mm before the apex straight to the centre of the inner margin, fine and distinctly black, inside finely bordered with yellow, the dark discal spot oval, finely and distinctly surrounded by black. Hindwing without any pink tint, greyish brown, with a yellow disc; ocellus quite black, in the centre some white scales. Abdomen deep black, at the end light yellow. Type: 1 ♂ from Merida, Venezuela, in the Senckenberg Museum.

A. curitiba *Schs.* Above greyish-brown, base of wings with a yellow spot, abdomen above purple red, beneath and at the anus ochreous. Forewing at the base and costal margin broadly brownish ochreous, margin light olive brown, discal spot feeble and only linearly surrounded; postmedian line straight from the apex to the centre of the inner margin, olive brown, inside pinkish white. Hindwing in the cell and at the inner margin purple red, ocellus dark brown with a white central line, broadly edged with black, in the yellow disc; the fine black interior subterminal line not reaching to the costal margin is distally bordered with yellow, behind it a purple red shadow, margin pinkish-grey. Curitiba (Brazil).

A. incarnata *Wkr.* (109 e). Varying between red-brown and olive brown, anterior transverse line irregular, posterior line straight from close before the apex to the centre of the inner margin, inwards more or less distinctly bordered with ochreous, discal spot rather inconspicuous, often with a white central dot and surrounded by black dots. Hindwing in the disc yellow, at the base and inner margin rosy red, ocellus large, round, iris greyish-black, with a white-strewn pupil, behind it a black line and a reddish band. Abdomen dark rosy red. Bogota (Colombia). — **cecrops** *Bsdv.* (109 c) is probably only the northern form distinguished by the more curved postmedian line, a slightly more falcate apex of the forewing and a lighter rosy red abdomen. Mexico to Panama. In North America (Arizona) the species is represented by — **pamina** *Neum.* (109 c) distinguished by its very light sand-coloured yellowish-grey ground, whilst a somewhat darker ochreous, reddish-strewn form is called — **aurosea** *Neum.* the exterior of which is very much like that of *boucardi* from which, however, it is easily separable by the pinkish red abdomen (being black in *boucardi*). Larva of *pamina*, when fully developed, above green, sublaterally and ventrally brown. With white subdorsal lines and white short lateral oblique stripes being above bordered with black and extending from in front above hindward beneath, separating the brown colour from the green; densely set with fir-tree-like tufts of stings, which are much longer on the first and last segments.

A. zephyria *Gr.* (109 e) is allied to the foregoing species, but easily separated from them by the absence of the antemedian line and by the postmedian line being inside broadly bordered with white and extending very obliquely from the apex to before the centre of the inner margin; ground-colour mostly darker brown. Disc of hindwing yellow, base, costal and inner margins with pink hair, ocellus and lines as in the preceding species. — f. **zephyriata** *B. & Benj.* is a deep red-brown instead of greyish-brown form and its relation to *zephyria* is like that of *aurosea* to *pamina*; intermediate forms may occur. New Mexico.

A. maeonia *Drc.* (109 d) for which PACKARD established the genus *Protautomeris* is marked somewhat like *zephyria*. Forewing light brownish-grey, in the median area often with a pink tint; basal and subterminal areas dark olive brown, both the transverse lines yellowish-white, on the averted sides with single ochreous scales; discal spot dark brown, especially in the ♀ often extended on the veins outward and inward in long

acute angles. Hindwing brownish-grey, marginal area like the median area of the forewing, the small ocellus rather dull, between the latter and the black postmedian line more or less extensive yellow colour. Abdomen above dark olive brown, in the ♀ blacker with claret-pink hair. Mexico.

orestes. **A. orestes** Bsdv. (= *hebe* Drc. nec Wkr.) (109 d). Forewing light yellowish greyish-brown, apically darkened olive brown, the light transverse lines fine, indistinct, the somewhat darker discal spot inside with 4, outside with 3 distinct black dots and a blackish central streak. Disc of hindwing of a bright chrome-colour, at the inner margin with light reddish-brown hair, marginal area as forewing; the large ocellus somewhat oval, blackish-brown, with a narrow black ring, in the centre strewn with white, postmedian line black, behind it a grey band. Guiana. The statement: Mexico is wrong and is due to DRUCE mistaking it for *hebe*.

serpina. **A. serpina** Btlr. is only known from the damaged ♀ type in the British Museum, being figured in CONTE. Accordingly, the species would have to be ranged near *orestes*; larger, with more pointed wings, hindwing with a longer inner margin and anal angle, distal margin less rounded. The colour is more light pinkish brown, the posterior transverse line somewhat nearer to the margin and originating parallel to it at the costal margin 10 mm before the apex, inwardly shaded with red-brown like the apical portion behind it. Hindwing in the disc more extensively yellow, basal part with light brown hair; the brownish iris of the ocellus is more extensive, the black ring narrower; the black line behind it more remote from the ocellus, more undulate. Expanse of wings: 11 cm. South America?

surinamensis. **A. surinamensis** Ky. (= *arminia* Stoll. p. p., *falcifer* Conte) (109 d) is distinguished by particularly falcate forewings; brown, in the anal half of the marginal area and often also in the centre of the inner margin lighter whitish-grey; antemedian line rather straight, postmedian line from more than 1 cm before the apex to the inner margin close behind the centre. Discal spot hardly darker, finely surrounded by blackish. Hindwing brownish-red, around the large ocellus yellow, the outer subterminal line forms a broad dark red band, abdomen dark red. Guiana.

innocia. **A. innocia** Schs. (= *altus* Conte) (109 d, e) is very similar to *surinamensis*, forewing somewhat less falcate, dark brown, in the marginal area pinkish-brown; anterior transverse line fine, black, undulate, at the inner margin more remote from the posterior line which extends straight from 9 mm before the apex to the inner margin; discal spot large dark, indistinctly surrounded by black with a small grey central dot. Hindwing violettish red, in the marginal area pinkish-brown, the very large ocellus in a yellow ring interrupts the black inner subterminal line. Head and thorax dark brown; abdomen light brown, above violettish-red. Expanse of wings: 77 mm. British Guiana.

pomifera. **A. pomifera** Schs. Head and thorax brown, abdomen above reddish; forewing brown, the black fine antemedian line very slightly undulate, the posterior line from 7 mm before the apex; discal spot oval, finely bordered with black, with a white central dot. Hindwing at the costal margin, base, inner margin, and subterminally reddish, at the distal margin light brown, disc bright yellow as far as the black subterminal line; the dark brown ocellus broadly bordered with black, with a black pupil crossed by a white bar. Expanse of wings: 72 mm. Peru.

macareis. **A. macareis** Schs. (109 e). Broad wings, pinkish-brown, basally and behind the postmedian line which extends from the apex to the centre of the inner margin darker, enclosing a subterminal brightening, antemedian line narrow, discal spot finely surrounded by dark. Hindwing pinkish-brown, between the ocellus and the subterminal line yellow, at the margin lighter; ocellus small, in the brown centre few white scales. Abdomen varying between reddish and carmine. Brazil (Petropolis).

naranja. **A. naranja** Schs. (= *ater* Conte, *umbrosa* Weym.) (109 e). Front body dark brown with single yellowish hairs, abdomen reddish-yellow, above extensively black-haired. Forewing blackish brown, basal area darker, the black antemedian line dentate, indistinct, discal spot almost round, often white-centred, in the lighter median area which is only darker towards the costal margin; postmedian line concave, terminating into the apex, the subterminal area behind it very dark. Hindwing orange, base and margins extensively covered with brownish-black hair, the blackish-grey ocellus in the centre white-scaled, the line behind it hardly undulate. Brazil, North Argentina, Larva greenish yellow with yellow branched burning hairs and large triangular oblique white, black-edged lateral spots beginning from the 2nd ring. The small brown cocoon is wrapped up in leaves.

complicata. **A. complicata** Bsdv. (109 e) is a characteristic species, above brown, with darker transverse lines and discal spot, the postmedian line from the apex obliquely to the centre of the inner margin. Hindwing deep brown, the black, white-centred ocellus in a deep yellow area; the only subterminal line likewise broad black; behind it the marginal area dark red-brown. Abdomen above black, beneath yellowish-brown. Venezuela to Brazil.

aurantiaca. **A. aurantiaca** Weym. (109 c) is similar to *complicata*, forewing more dark yellowish-brown or olive brown, towards the margin in the centre of the distal margin turning almost light grey, the postmedian line inwards very narrowly bordered with ochre, instead of the discal spot 3 dark brown dots; the disc of the hindwing is brighter orange, at the costal margin and base dark grey, at the inner margin almost black; the ocellus is more oval, in the pupil beside the white strewing a fine white line. Abdomen almost black, with light yellowish-grey hair. Southern Brazil.

umbrata. **A. umbrata** Bsdv. (= *uruba* Plötz i. l.) (110 a). Forewing brown with a more or less distinct blackish, almost straight median shadow, the fine light postmedian line near the margin, from the apex, somewhat

concave towards the margin. Hindwing dark yellow with a slight greenish tint, basally and at the inner margin with blackish and brownish red hair, the small ocellus blackish grey with a white pupil and a broad black ring; behind it follows a broad black band, behind which there is another band. Brazil.

A. inornata Wkr. (= fumosa Bsdv.) (110 a). A very variable, unicoloured blackish grey species more *inornata*. or less tinted brownish, only the abdomen showing some yellowish ochreous hairs; forewing basally and behind the slightly concave postmedian line darkened, the roundish darker discal spot mostly white-centred. Hindwing with a dull darker ringed, blind ocellus and 2 arcuate lines behind it, the interior line darker, sometimes feebly undulate, the posterior one somewhat broader and lighter. In the ♀ the abdomen shows more distinct ochreous rings. Common in Brazil. — **obsoleta** Niepelt is surely an albino variation of this species with exactly the same *obsoleta*. scheme of markings, of a much lighter, pale yellowish-grey colouring and an especially lighter ochreous body. The type from S. Paulo has been before me through the kindness of Mr. NIEPELT. Such albinisms seem to be of frequent occurrence in the genus *Automeris*, a very fine specimen from the Berlin Museum, evidently belonging to *basalis*, shows on its pale yellowish-grey ground all the markings, also the ocellus, only feebly marked as darker shadows.

A. violascens Maass. (114 g) is an entirely different insect which, however, does not fit into the genus *violascens*. *Hylesia*. Sooty black, thinly scaled, abdomen intermixed with scanty ochreous hairs; the obsolete marking consists of 2 shadow-like widened transverse lines, the inner one quite indistinct, the outer one feebly incurved from $\frac{2}{3}$ of the inner margin to shortly before the apex, between both a hazy thick discal spot. On the similarly coloured hindwing the ocellus is feebly ring-shaped, very hazily showing through from beneath, close at it a very obsolete postmedian line, behind which the somewhat more distinct subterminal line follows, approaching the margin. Sa. Catharina.

A. modesta Mén. (= midea Mssn., aspersus Bouv.) (110 b). Forewing dark yellowish-brown, the *modesta*. anterior transverse line hardly visible, yellowish, the posterior line yellow, from about 5 mm before the apex almost parallel to the margin to about 5 mm before the inner angle, before it at the costal margin intensely white-haired, in the narrow marginal area with a very feeble yellowish undulate subterminal line; the discal spot is feebly darkened grey, distally three-pronged with fine black dots in the tips and one in the centre. Hindwing on the copper-red ground darker and more blackish than forewing, only at the margin the same; the ocellus surrounded with a yellow ring which is outside finely bordered with black, the yellow inner border of the black undulate subterminal line inwardly edged with blackish, too. Guiana to Brazil (Para).

A. bilinea Wkr. (110 b) is not dissimilar and easily discernible by the dull violettish brick-reddish tint *bilinea*. of the disc of the hindwing; forewing lighter and intensely strewn with whitish violet, the purest white in the basal area and at the costal margin before the apex, the marginal area remains purer yellowish, the postmedian line more bent and extending directly from the apex to about 8 mm before the inner angle; also here the yellow ring of the ocellus is outside finely bordered with black like the very fine yellow interior border of the subterminal line. From Brazil (Para). — **vividior** f. n. is very similar, somewhat smaller, still more contrastingly *vividior*. strewn with white, abdomen yellow, hindwing in the disc bright yellowish-red, the light yellow ring around the ocellus broader. Probably only the Guiana-form of *bilinea*.

A. orneates Drc. (108 d, 110 c) is most similar to *modesta* and unmistakable. Shape of wings remarkably *orneates*. high, with very falcate apices; brown, at the apex almost black, before it with a broad, often obsolete ochreous oblique band; subterminal line close at the margin and parallel to it. Hindwing almost black with a small yellow-ringed ocellus, the narrow marginal area brownish ochreous. In the type from the Berlin Museum the ochreous oblique band of the forewing is darker, browner than in other specimens. The much larger ♀ is purple brown, densely strewn with violettish white. — **phrynon** Drc. (110 c), as STAUDINGER already presumed, is *phrynon*. surely only an albinistic light ochreous ♂ with a merely shadow-like ocellus, only the white centre being visible. From Panama, Honduras, and Colombia.

A. tristis Bsdv. (= hagar Niep.) (110 b) forms the transition from *orneates* to the following *falcata-tristis*. group. Above sooty blackish-brown, anterior transverse line very indistinct, the posterior line from shortly before the apex to about 1 cm before the inner angle, dark yellow; discal spot large, shadow-like blackish. Hindwing similarly coloured as forewing, with an orange-ringed, white-centred black ocellus nearing the margin as in the *janeira*-group and being proximally flatly concave; subterminal line little visible, inwards feebly yellowish. The ♀ is still darker, the ocellus very slightly encircled with yellow. Sao Paulo; Novo Friburgo.

A. hamata Schs. (= angulatus Conte, hippodice Mssn. i. l., ♀ insolens Bouv.) also has a very falcately *hamata*. produced apex of the forewing; brown, the darker transverse lines at the inner margin very near together, the interior one below the median inwardly interrupted to the centre of the inner margin, the exterior one proceeding from a little more than $\frac{1}{2}$ cm before the apex, where it is inwardly very intensely strewn with white; discal spot grey, finely surrounded with black. Hindwing orange brownish, ocellus and subterminal line as in *bilineata*, also the yellow margins once more finely bordered with black, the iris very extensively reddish-brown. The ♀ has more normally shaped wings and is more violettish-brown. Costa Rica, Venezuela

columbiana. to the Amazons (before me from Pebas, e coll. *Stgr.*). — **columbiana** *f. n.* is larger, much brighter yellowish red-brown, the median area slightly tinted violet, the transverse lines very distinct, the discal spot much larger, slate-coloured black, outside and inside notchedly surrounded with dark brown. Hindwing bright orange-red, turning rosy-red at the costal margin, the marginal area also coloured like that. Western Colombia (Bella *panamensis*. Vista). Type in the Coll. NIEPELT. — **panamensis** *f. n.*, the form from Panama, on the contrary is somewhat smaller, of a duller colouring, the hindwing not orange but light brown, the black ring of the ocellus of double width. Type in the Coll. B.-HAAS.

falcata. **A. falcata** *Bsdv.* (111 b). Wings elongate with a far produced pointed apex, dull brownish-grey with a lilac tint, transverse lines yellowish, on the averted sides darker brown, the exterior line from 8 mm before the apex, terminating at the inner margin 5 mm behind the interior line; discal spot oval, darker greyish-brown, finely surrounded with yellowish. Hindwing greyish claret-coloured, ocellus black with single white scales and a short white angular streak, with a dark yellow ring, subterminal line very undulate, outside of it a very indistinct red-brown undulate narrow band. Cayenne.

norcestes. **A. norcestes** *Bsdv.* (= *maasseni* *Mschlr.*) (110 c) looks almost exactly like *falcata*, but the ocellus is smaller with a distinct red iris and a more intensely white-strewn pupil, and a broader orange ring. The larger ♀ has normally shaped wings and is thinly scaled, with darker brown veins, the two greyish-white transverse lines almost or quite contiguous at the inner margin. Guiana. Amazons.

janeira. **A. janeira** *Westw.* (= *fumata* *Bsdv.*) (110 c) is extraordinarily similar to the following *cinerea*; shape of wings somewhat higher; besides distinguished by the redder disc of the hindwing, the red not yellow ring around the ocellus with a more extensively red iris and a reduced black ring; the small pupil is more intensely strewn with white; the whole hindwing is shorter and rounder. Brazil; Colombia?

cinerea. **A. cinerea** *Wkr.* (110 d) is a well-known species, the ♂ with a very falcate apex of the forewing, deep chestnut, the posterior transverse line in its lower portion yellowish. Hindwing coloured the same, with a red ocellus with a broad black, then narrow yellow ring. The ♀ is more greyish-brown, in the marginal area lighter, with fine darker veins, a conspicuous oval discal spot surrounded by greyish white, and yellow transverse lines being dark brown on the averted sides. Brazil.

acuminata. **A. acuminata** *M. & W.* (110 d). By the narrow yellowish-grey, black-dotted forewing with 2 yellowish subterminal lines from the apex, and the lemon-coloured hindwing the species is easily discernible and unmistakable; the black ocellus with a white-strewn iris and a white central crescent is somewhat oval, behind it a black line and a somewhat broader, greyer one in the brown marginal area. Brazil.

fusca. **A. fusca** *Wkr.* (= ♂ *combusta* *Wkr.*) (111 a) is very similar to the following *saturata*, but it has only a narrow yellow ring round the ocellus of the hindwing. The ♂ is deep red-brown, the ♀ more greyish-brown, as in *cinerea*. Specifically hardly separable from *saturata*. South America? From Balzapamba (Ecuador).

saturata. **A. saturata** *Wkr.* (= *schausi* *Edw.*) (110 d). Forewing red-brown with a darker oval discal macula narrowly surrounded with yellowish, and two darker, inwardly yellowish transverse lines strongly convergent towards the inner margin. Hindwing of a bright chrome colour, basally, at the costal and inner margins black-haired, with a broadly black-edged red ocellus and an oblong black pupil which is incompletely surrounded with white, behind it an undulate black line, then an interrupted brownish-red shadow-line in the brownish marginal area. Mexico (Jalapa).

nyctimene. **A. nyctimene** *Latr.* (= *damocus* *Bsdv.*) (110 e) is a large species with a most variable ground-colour, greyish-brown, dark red-brown, light rusty brown, with 2 darker transverse lines nearing each other at the inner margin and being more or less bordered with reddish yellow on the inverted sides, between them an oval, dark discal macula with a yellowish ring and often also a light pupil; veins, especially distinct in the ♀, in the marginal area lighter yellowish. Hindwing greyish-black with a very large Pompeyan red ocellus in a black ring and surrounded by yellow, the oblong black pupil parted near the proximal end by a blue-white transverse bar, incompletely surrounded by white strewn and on each side flanked by a small oblong, white-dusted guttiform spot; postmedian line black, undulate, behind it a broad brownish-red interrupted shadowy band, marginal area coloured as forewing. Brazil, Colombia. — **leucane** *Hbn.* (110 e) is the northern form, somewhat smaller, of a duller colouring, the postmedian oblique line straighter, arising nearer at the apex; on the hindwing the ocellus is smaller, the iris duller red, the yellow ring narrower and lighter. Mexico. Larva coal-black with light yellow tufts of stings. It lives on "Troena" (?).

acutissima. **A. acutissima** *Wkr.* (111 a) is surely different from *nyctimene*, smaller, in the ♂ with much narrower wings, the apex being long falcate; especially the ♀ is more thinly scaled, with more distinct light veins; on the hindwing the ocellus is larger on an average and, especially in the ♂, removed nearer to the margin, similarly as in the *cinerea*-group, the iris of the ocellus much darker brownish-red, only around the pupil lighter yellowish. It flies beside *leucane* in Mexico.

A. mülleri *n. sp.* (111 a) is another very similar species of this group; as large as *acutissima*, but the *mülleri*. apex of the forewing not so far falcately produced, greyish-brown, densely dusted with greyish-white, particularly in the marginal area of the forewing, the veins also in the ♂ marked yellowish-white, the transverse lines, especially the outer one, much more broadly shaded dark brown, between 5 and 7 with a distinct inward curve; discal spot below the centre rather much strangulated, in the inner half mostly darker than in the outer one, with a long light central streak. On the hindwing the two anteterminal lines are very near together, the margin itself is very light, sometimes almost creamy white. Abdomen almost black with reddish-yellow anal hairs. Mexico (Zacualpan); numerous specimens of both sexes, type in the Coll. DRAUDT.

A. memusae *Wkr.* (= *viridescens* *Wkr.*, *mimusops* *Bsdv.*) (111 b) is exactly like *falcata* in the forewing, *memusae*. the apex of the forewing is less pointed, the distal margin not so concave, the transverse lines more distinct, the hindwing marked as in *acutissima*, but the ground rather lighter than the forewing; ground-colour variable, light greenish-grey, greyish-brown, or deep red-brown. Brazil to Argentina; a common species.

A. gibbosus *Conte* (110 e) is a large form, several specimens of which are before me from Rio Grande *gibbosus*. do Sul, of a mostly very bright red ground-colour, the posterior transverse line distinctly black. On the hindwing the distal edge of the ocellus is undulate corresponding to the undulate border of the postmedian line. In CONTE the signatures of the figures of *memusae* and *nopaltzin* have been confounded. Larva black with straw-coloured tufts of stings.

A. apollinairei *Dogn.* is allied to *gibbosus*; thorax and forewing pale pinkish lilac, towards the costal *apollinairei*. margin yellowish ochreous, in the marginal area with ochreous veins, the transverse lines light ochreous, too, the inner line inwards olive, from the first fifth of the costal margin straight to the inner margin, where it is connected with the exterior line which runs straight to the apex, where the yellowish colour is very broad; the oblong discal spot is likewise ochreous. Hindwing light olive grey, little strewn, with a large ocellus surrounded by yellowish, exhibiting one large and two small black and dark red centres; the black regularly dentate line behind it is inside bordered with light ochreous, the subterminal line on both sides bordered with yellow and interrupted on the veins. Colombia.

A. lama *Berg* (= *joannisi* *Bouv.*) connects the *gibbosus* and *stuarti*-groups. Scheme of markings as in *lama*. *stuarti*, shape of wings more as in *gibbosus*; forewing blackish grey, veins and transverse stripes in the ♂ white, in the ♀ yellowish, much less distinct than in *stuarti*, the stripes not contiguous at the inner margin, the anterior transverse streak forms an obtuse angle in the cell close above the median vein, the posterior one proceeds from close before the apex; basal and submarginal areas more intensely darkened blackish like the discal spot which is bordered with whitish. Hindwing smoky grey, behind the ocellus lighter, the ocellus similar as in *gibbosus*, transversely oval, behind it a very undulate fine black line, behind it a less distinct line, both crossed by the yellowish-brown veins. Expanse of wings: ♂ 60 mm, ♀ 73 mm. From Argentina (Salta, Tucuman).

A. bivius *Bouv.* is described to be very similar to *lama*. Body above brown, beneath yellow, forewing *bivius*. above red-brown; transverse lines much more distinct and broader white, the posterior line from the apex, touching the much larger discal spot which is distinctly surrounded by white; basal and subterminal areas not darker than the ground. Hindwing much lighter and more yellowish; iris of ocellus redder, fringe distinctly white. Apex of forewing much less falcate than in *lama*. Expanse of wings: 67 mm. Described from a single ♂, patria unknown.

A. stuarti *Rothsch.* (111 b). Forewing blackish olive brown, with distinct creamy-white veins, two *stuarti*. creamy-white transverse lines almost touching each other at the inner margin, and a large round discal ring. Hindwing light olive grey with 2 undulate-dentate subterminal lines, the exterior one being broader and paler, and with a black, somewhat oval ocellus with an olive iris and a large black pupil the proximal and discal margins of which are strewn with white. Bolivia (La Paz); Argentina and Paraguay.

A. heisleri *Jones*, to a certain degree, is allied to *aspera*. Body and forewing greenish-grey, costal *heisleri*. margin of forewing narrow orange brown; the fine orange brown antemedian line is strongly distally angled between the origins of 2 and 3; the large discal spot is darker grey; finely bordered with orange brown; the exterior transverse line extends from the inner third of the inner margin to the apex, it is orange brown, outside bordered with dark grey; marginal area lighter, subterminal line very indistinct. Hindwing yellow, strewn with grey, at the inner margin with blackish-brown hair; the interior transverse line is fine, black, behind it a reddish brown band, marginal area greenish grey; the very large black ocellus exhibits an iris being densely scaled red-brown, a large oblong black pupil in a light reddish-yellow ground with a white transverse bar, inside and outside strewn with white, as well as 2 black small accessory spots. Expanse of wings: 91 mm. Curitiba (Parana).

A. aspera *Fldr.* (111 b). Forewing brownish-grey, strewn darker, with a darker, white-centred discal *aspera*. spot and very undulate-dentate black transverse lines, the anterior and the subterminal lines being less distinct. Hindwing either pale olive yellowish-grey, or with a feeble pinkish tint: — *rosacea* *f. n.*, and a finely black- *rosacea*. edged ocellus with an orange brown strewn iris and a black pupil; the latter, excepting its feebly white-dusted distal edge, is situate in a horseshoe-spot of the ground-colour and inside bordered by a straight white streak.

on both sides it is flanked by smaller black, white-strewn spots in the orange brown ground; they may also be absent. Southern Brazil (S. Paulo); Uruguay; Paraguay; Argentina. A common species.

submacula.

A. submacula Wkr. (111 A a) is a larger species, forewing light reddish-yellow, with feebly visible whitish dentate transverse lines and a somewhat darker, white-central discal spot. Hindwing lemon-coloured, behind the ocellus scantily strewn with blackish; ocellus with a velvety black ring, iris outside narrowly lavender-blue, inside cinnamon-reddish with a large quadrangular white pupil; before the yellowish-reddish margin 2 transverse lines, the interior one fine, black, undulate-dentate, the exterior one represented by broad blackish spots interrupted by the yellowish-red veins. Abdomen as forewing. Brazil (Parana). — **dioxippus** Bsdv.

dioxippus.

(111 A a) is smaller and darker, forewing dark brown with rusty yellow veins, and densely strewn and haired white, with a white basal spot, indistinct dentate transverse lines, and a white-centred darker discal spot. Hindwing light yellow, in the distal half strewn with black, the ocellus with a velvety black ring; iris in the distal half lavender-blue, inside rusty brown with a white pupil; postmedian line fine, black, undulate-dentate, behind it there are blackish subterminal spots outside strewn with white and interrupted by reddish-yellow veins; margin rusty brown. Abdomen reddish-yellow. Brazil; Yungas, Bolivia.

oberthurii.

A. oberthurii Bsdv. (111 A a). Forewing of the same greyish-brown, darker and white strewn ground-colour as in *aspera*, the transverse lines very feeble and indistinct, only very little dentate, the very small discal spot feebly centred greyish-white. Hindwing yolk-coloured, the black-ringed ocellus with an olive brown iris and a large black, densely white-strewn pupil; but one strong black, not dentate transverse line, behind it a brick-red shadow-like band, separated from the light greyish-brown margin by a narrow yellow line. Argentina (Cordoba, Buenos Ayres).

granulosus.

A. granulosus Conte is so closely allied to *oberthüri* that it is presumably only a variable specimen; it differs in darker red-brown forewings with white strewing in the distal half of the median area and of the marginal area; moreover, there are two yellowish transverse lines, the anterior one uninterrupted, the posterior one beginning at the costal margin about 8 mm before the apex and extending in a slightly distal convex curve parallel to the distal margin to the inner margin. Described from a ♀ from Brazil e Coll. OBERTHÜR.

castrensis.

A. castrensis Schs. (111 A a) is a smaller species with narrower greyish-brown, strewn forewings, a large whitish discal ring finely surrounded by dark, and a very oblique exterior somewhat darker transverse line. Hindwing light yellow, at the inner margin and around the ocellus with a very feeble reddish tint; the large ocellus is black, the iris dark olive brown with a large black, white-strewn pupil; the inner blackish transverse line directly adjoins to the outer somewhat lighter shadow-like stripe, a fine whitish line separates from the light brownish-grey margin; costal margin of the same colour. Abdomen crimson. Brazil (Parana; Minas Geraes).

eophila.

A. eophila Dogn. (= *aurora* Dogn., nec Weym.). Forewing brown with an oblong-quadrangular, black-edged discal spot with a white central dot bordered with yellow; the black transverse lines on the averted sides bordered with yellow, the anterior line submedianly angled, the exterior one sharply and regularly dentate, the points of the dents on the veins, incurved below 2; the irregular subterminal line a little white-strewn, with a black marginal line before the brown fringe being speckled white on the ends of the veins. Hindwing pinkish-red, with a round black ocellus, a greenish-yellow iris and black pupil with a white discoidal streak; behind the ocellus a well rounded black line, behind it a chain of whitish, brown centred internerval rings, the brown marginal area with ochreous veins. Expanse of wings: 49 mm. According to a ♀ from Tucuman (Argentina).

brasilensis.

A. brasilensis Wkr. (= *porus* Bsdv.) (111 b). This and the following 3 species are all very closely allied to each other. Forewing dull yellowish red-brown with a white basal spot and brown transverse lines, the posterior one beginning close at the apex, without white vein-dots; median area somewhat lighter, the contours of the discal spot marked by black dots. Hindwing red-brown, basally and towards the inner margin darker, the large black ocellus surrounded by yellowish, with a reddish-grey pupil outside extended into 3 or 4 points, enclosing a fine white angular bar; behind the black undulate subterminal line with a rusty red band, marginal area rusty yellowish. Brazil.

huebneri.

A. huebneri Bsdv. (= *quadridentata* Ky.) (111 c) is somewhat lighter red-brown, the posterior transverse line straighter, only near the inner margin slightly curved, and dotted white on the veins; hindwing still lighter, in the disc whitish-yellow, with a horseshoe-shaped pupil-spot being distally extended into 4 points, enclosing a very small white angular bar; marginal area yellowish-grey. Brazil (Minas Geraes).

coronis.

A. coronis Schs. (111 c) is larger than the two preceding species, abdomen red-brown with feeble smoky grey transverse bands. On the brown forewing the median area is somewhat lighter, greyer, the light brown discal spot very large, inside with 2, outside with 4 black dots; both the antemedian line forming two bows and the fine reddish-brown postmedian line are marked with yellowish-white dots on the veins. Hindwing at the base and inner margin dull pinkish brown, the very large ocellus black, broadly encircled with yellowish-white, the brown pupil-spot extended into 4 points, with a white angular bar in the centre; behind the ocellus

an undulate black line with a broad chestnut-brown band behind it. Fringe light reddish ochreous. Expanse of wings: 95 mm. Joinville, Brazil.

A. amphirene *Bsdv.* (= *porifera* *Strd.*, *melanops* *Conte* in tab.). Size and shape of *brasiliensis*; hindwing *amphirene*. greyish-red, basally spotted white, in the median area lighter; with brown transverse lines, the posterior line inside on the veins dotted white, extending near to the apex. Discal spot hardly darker, with a three-pronged, black-dotted exterior edge, often containing a small white dot. Hindwing light reddish-brown with a large black, yellow ringed ocellus with the horseshoe-shaped greyish-yellow iris containing a white angular streak; behind it a strongly undulated black line with a red-brown band behind it. Abdomen greyish brown. Brazil. This species is probably merely an insignificant, somewhat larger form of *hübneri*. The type of *porifera*, which was before me through the kindness of Dr. HORN, belongs to this species judging from the shape of the discal spot.

A. irene *Cr.* (= *luteata* *Wkr.*) (111 d). Forewing of ♂ varying between yellow and rusty reddish-brown, *irene*. of ♀ darker, the anterior transverse line indistinct, almost straight and vertical to the inner margin, strewn with whitish, the posterior line brown, beginning a little before the apex, inwards dotted white on the veins. Hindwing reddish-brown, in the ♂ more rusty yellowish, the large ocellus narrowly surrounded by light yellowish, with a two-pronged yellowish-grey iris and a white angular streak. Guiana. Larva light grey with darker segmental indentations and branched green thorns, beginning from the 4th ring with a yellow lateral stripe which is bordered with dark red above. It lives on pomegranate trees.

A. scapularis *Bsdv.* (111 d) is very similar to *irene* and perhaps only its Brazilian form. Forewing still *scapularis*. somewhat more pointed, ground-colour lighter, postmedian line yellowish, with hardly any white vein-dots, the discal spot with intense black dots. On the hindwing the ocellus is more broadly surrounded by yellow, the yellowish-grey iris three-pronged. Abdomen monotonously reddish greyish-brown. Common in Brazil.

A. metea *Stoll.* (111 d) has broader wings with less pointed apices, darker red-brown, in the ♀ more *metea*. lilac greyish-brown, the antemedian line projecting distally twice sinuate in and below the cell, postmedian line more intensely dotted white, discal spot surrounded by more intense black dots. Hindwing lighter, redder, the iris smaller and narrower. Brazil.
